Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38·4°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, January 2, 10 a.m. Bar. 30.4 Temp. 38°. Weather, Fine.

Sir William T. Thiselton-Dyer.

SIR WILLIAM T. THISELTON-DYER, who died at his home at Crickley Hill, near Witcombe, in Gloucestershire, on December 23, 1928, had been out of the public eye for years, but had kept in touch with his friends, although for some time past it was felt that the weight of his eighty-five years was telling more and more heavily on him. What influences exactly turned Dyer from the medical career for which his father—himself a well-known London practitioner of the middle of the last century—intended him, we do not know, but about a year after he had left King's College School, where he had Professor George Saintsbury as a co-pupil, and entered King's College with the intention of taking a medical degree through the metropolitan schools, the call to science—spontaneous or induced—led to his migration to Oxford, and he figures on the roll of Christ Church College for 1863. Dyer was then at the impressionable age of twenty, and among his teachers at Oxford were Rolleston and Daubeny, both of whom influenced him, the former by his sowing in Dyer's fertile mind the seeds which came to fruition in the methods of botanical teaching Dyer adopted when he, in turn, assumed the *rôle* of master, and the latter in more ways than one. Daubeny was then absorbed in the chemistry of plants and in agricultural experiments, while also intent on investigating the plants of the ancients, all of which gave a lasting trend to Dyer's botanical interests; indeed, to the end of his life the plants of the classics and their identification, whereon there is so much difference of opinion, was a subject very near Dyer's heart. He wrote many a critical disquisition on the subject, about which he knew more than most. After five years at Oxford, Dyer was called to the Chair of Natural History at the Royal Agricultural College at Cirencester, and during the two years he was there, he and Trimen published their *Flora of Middlesex*, while, jointly with Arthur H. Church, who was then Professor of Chemistry at the same College, he edited a British edition of a textbook, *How Crops Grow*, by S. W. Johnson, Professor of Agricultural Chemistry at Yale University. From Cirencester, Dyer graduated B.Sc. from London University and, while only twenty-seven, went to Dublin as Professor of Botany at the Royal College of Science. He was soon back, however, in London as Professor of Botany to the Royal Horticultural Society at South Kensington, and there he came into contact with Huxley, and renewed an earlier acquaintance with Charles Darwin, which was afterwards to ripen into a mutual regard. At that time (1872) Huxley, who soon recognised the qualities of the comparatively young occupant of the R.H.S. Chair of Botany, entrusted to Dyer the organising of the botanical part of the laboratory course of biology which he (Huxley) had just then initiated at South Kensington, and this gave to Dyer the opportunity of divorcing the education of the botanist from that of the medical student to which it had been tied of old, and placing botany on its own feet, as it were, as a natural science. This involved the introduction of laboratory work and demonstration—and all that they both mean—not in substitution of the field excursions, which, up to then, had been the only source of practical instruction in botany, but side by side with them. Dyer's work on Huxley's staff brought him into touch with the brilliant men of science of the day who formed the "South Kensington Circle" and, doubtless, influenced his appointment to the post of Assistant Director of Kew Gardens, an office of which he was the first occupant after its suppression by the Office of Works at the time when Sir Joseph Hooker was made Director. At one and the same time, that appointment brought Dyer's seven years of professorial life to an end and began his career as administrator—for the rest of his official life was spent at Kew. The second period of Dyer's active life began in 1875 with the appointment referred to above, and ended thirty years later after he had been Director of Kew for two decades. Those thirty years were pregnant of incident to Dyer in a personal sense—for two years after his appointment as Assistant Director he married his chief's daughter—and to Kew, which, when he joined the staff was the National Botanic Garden, and when he laid down the reins had become the mother garden of the Empire. Nowadays, we are apt to take it as a matter of course that there should be a botanic garden more or less in every country where the Union Jack flies, and that it should be directed by a Kew-trained man receiving all that Kew has to bestow of tradition, experience and practical knowledge, giving what it can in exchange and confiding some, at any rate, of its many troubles to its mother. That such a condition of affairs exists to-day is primarily due to Dyer. The conception of Kew as an Imperial institution was Dyer's, and he lived to see the fulfilment of his vision and its expansion by his successors. In its wider aspects, Kew of to-day, with apron strings stretching to the distant corners of the Empire, is a great monument to an able administrator, who achieved his end despite the inevitable prejudice, opposition and inertia which are apparently inseparable from public life. Although the overseas interests of Kew were an obsession with Dyer, he did not neglect the internal side of the administration. During his occupation of what he jestingly called the "papal throne" at Kew, Dyer conceived and, in 1887, began the publication of the *Kew Bulletin of Miscellaneous Information*, which was originally intended to assist colonials who were engaged in the production or exploitation of economic vegetable products. It is to Dyer, too, that we owe the *Museum Guides*, which he commenced after he had completed the reorganisation of the Museum. The Herbarium came under Dyer's reforming hand later, and he was able to add a good deal to the space available to his predecessor in office. During his directorship, the Jodrell Laboratory, which owes its existence to the munificence of the individual whose name it perpetuates, was established and equipped; the Temperate House, which had been commenced years before, was completed, and most of the glasshouses were rebuilt. Administrative duties absorbed so much of Dyer's time that, to the lasting regret of his friends, he had but little leisure for literary work. Soon after his appointment as Assistant Director, however, he began the editing of the *Flora Capensis*, which Sir William Hooker had originally suggested in 1863, and of which three volumes had been published before further progress was interrupted in 1865. The *Flora*, towards the cost of which the Governments of the Cape, Natal and the Transvaal made themselves responsible for the sum of £3,250, continued to engage Dyer's energies for some years after he had retired from Kew, and was finished in 1925. At the same time, as editor, Dyer resumed the publication, for the British Government, of the *Flora of Tropical Africa*, which also owed its inception to Sir William Hooker, and like the *Flora Capensis* had been commenced and allowed to stop. Dyer continued the editing of this until 1913, and the *Botanical Magazine* until 1907, when the tasks devolved on his successor, Sir David Prain. Apart from the above, and his incursions into the field of classical plant-lore, Dyer's literary work was mainly confined to a translation of Sachs's *Textbook of Botany* (1875), for which he and A. W. Bennett were jointly responsible. Dyer wrote with an easy, scholarly pen, and his tribute to the memory of that remarkable man, Sir Henry Collett, in the latter's *Flora Simlensis* (1902) is a happy example of his work. After Dyer had retired from official life, he represented his old University on the Gloucestershire County Education Committee, and he served on the Committee of the Bristol University. He was created C.I.E. in 1892, and K.C.M.G. in 1899. He was Vice-President of the Royal Society in 1896-97. In social life Dyer was a delightful companion; he had known the great men of science of the late Victorian era who foregathered at the Athenaeum—Owen, Charles Darwin, Huxley and the rest—and his reminiscences, especially of Darwin, were always of interest. He was never chary of counsel to those who sought it, and few young men asked his advice in vain. In his official career, Dyer was a *sahib* and something of a dictator, who, for all his autocratic ways, inspired affection, respect and loyalty in his staff. Kew and its welfare came before all else; he knew just what he wanted and generally attained it. If it was worth fighting for, he would fight for it to the end; and if, while in pursuit of his object, his feelings sometimes proved stronger than his judgment, as doubtless happened when he worked for the removal of Kew from the province of the Office of Works to that of the Board of Agriculture, as it was then, that is a very human failing.

Our Coloured Supplement Plate.—The coloured Supplement Plate presented with our first issue of 1929 depicts two very beautiful bearded Irises, *i.e.*, Eldorado and Iris King, both fine garden plants obtainable at modest prices. Eldorado belongs to the Squalens group, is about two-and-a-half feet high when flowering, and has handsome flowers which show a charming combination of gold, golden-bronze, mauve and purple. Iris King belongs to the Variegata group and is also about two-and-a-half feet tall when in bloom. The flowers are golden yellow, with bright crimson shading and veins on the broad limb of the falls. Both varieties flower in June.

Church in a Garden.—One of the most picturesque of the English churches in foreign countries is that of St. Alban, in Copenhagen, which stands in a pretty park. It is built by the side of a miniature lake, and is approached from the city by sylvan pathways. Close to it is the beautiful waterway known as the Sound, the banks of which form a charming promenade, and not far away is the beautiful sculptured mermaid on a group of rocks which is called, by English visitors, the "Peter Pan" of Copenhagen. The rural peace and tranquility of the scene are enhanced, rather than broken, by the silvery chimes of the bells which mingle with the rippling of the water.

Work for Unemployed in London Parks.—In order to relieve unemployment in special areas, the authorities have arranged three months' work for eight hundred men, at an estimated cost of £20,000, in several of the London parks. Drainage and repair work is to be done in Rotten Row, St James's Park and Kensington Gardens, and in the last-named place the grass area around the children's sand-pit is to be planted. In other Royal parks, especially at Richmond Park and Bushey Park, there is a lot of ditching, road repairing and plantation work to be done.

Polyploidy. — In commemoration of the centenary of the birth of John Innes, the Council of the Horticultural Institution is holding a Conference on "Polyploidy as a Source of Species and Horticultural Varieties." The Conference will begin at 2.30 p.m. at the John Innes Horticultural Institution, Merton, on Saturday, January 19, 1929. Tea will be provided.

Sutton Bonington Conference.—The Horticultural Organisers for the Midlands area are holding their quarterly Conference at the Midland Agricultural and Dairy College, Sutton Bonington, Loughborough, on Wednesday, January 9, at 2.30 p.m., when Mr. Montagu Allwood, of Haywards Heath, Sussex, will give an address, illustrated by lantern slides, on "Carnations." All who are interested are cordially invited to attend.

New Zealand Nature Reserves.—A policy of making State-owned nature reserves, with a view to preserving scenic features and protecting the flora and fauna, is being steadily pursued in New Zealand, so that the number of such reserves is now eight-hundred-and-six; since 1904, nearly half-a-million acres have been purchased by the State, at comparatively small expense, for these purposes. Some of the reserves are at present not easy of access, but will be better appreciated as settlement advances, while some are small and others are of no value for cultivation. A description of the recently acquired reserves is given in the *Scenery Preservation Report*, 1927-28, of the New Zealand Department of Lands and Survey, together with an account of the flora and fauna of Kapiti Island, situated at the western end of Cook Strait.

Monsieur Emile Lemoine.—M. Emile Lemoine, the famous nurseryman of Nancy, France, is the son and heir of the late M. Victor Lemoine, whose name is known throughout the world as the raiser of (among many other good things) the popular Begonia Gloire de Lorraine. M. Emile was born at Nancy on January 11, 1862, and joined his father in the nursery so soon as he had completed his scientific education under the direction of M. G. le Monnier, one of the most famous French botanists of his time. The Lemoine establishment has always been in the nature of a research laboratory, and a large proportion of its activities consist in hybridisation, in which Victor Lemoine's wife and two daughters have taken a prominent part. M. Emile Lemoine is responsible for the creation of a new race of Gladiolus, G. Lemoinei, which has added fresh lustre to the already high renown of the Nancy nursery, and in many other directions he has revolutionised previously existing standards, as in, for instance, Lilacs, Deutzias, Paeonies and Delphiniums. He was Secretary of the Société Horticole de Nancy from 1892 to 1919. In 1921, he was created Commander in the Ordre du Mérite Agricole, and in 1928 he received the signal honour of the ribbon and cross of the Légion d'Honneur. Few horticulturists have better deserved this distinction.

M. EMILE LEMOINE.

Eucalypti in California.—A key to the species of Eucalyptus grown in California, composed by Eric Walther, was published recently in the *Proceedings of the California Academy of Sciences* (4th series, Vol. XVII, No. 3; 1928). The author states that the most striking of California's cultivated trees are easily the several species of Eucalyptus—"Their towering serried ranks dominate the landscape and lend it a unique, exotic flavour totally lacking in other parts of the United States." The species most generally planted at the present day is E. Globulus, but a few years ago—during the boom—many other species were tried, but owing to lack of knowledge of the particular requirements of many of these species, few of them have proved successful. It is the view of Mr. Walther that before further attempts at growing Eucalypti or introducing them are made, statistics regarding the species to be found already in California, and their relative status, should be collected, and it was with this object that he prepared his key. He enumerates one hundred species and varieties actually in cultivation in California to-day, the majority of which are to be found in Golden Gate Park, San Francisco; on the University Campus at Berkeley; and at the former Experiment Station at Santa Monica. The key is based on the late J. H. Maiden's work (*A Critical Revision of the Genus Eucalyptus*), and attached to the key is an alphabetical list of the species dealt with; there is also a list appended of seventy-seven species which, it is stated, "have been reported at various times as grown in California, or seed has been offered."

Pyrethrum Production in England.—It would appear that the growing and harvesting of Pyrethrum for the production of Pyrethrum powder can be carried out successfully and in a practicable way in this country despite the inclemency of our climate, judging from the first part of a paper on this subject, contributed to the *Annals of Applied Biology*, Vol. XV, No. 3, by Messrs. J. C. F. Fryer, F. Tattersfield and C. T. Gimingham, who have, during recent years, fully investigated the question of whether Pyrethrum, grown under English conditions, still retains its toxicity from an insecticidal point of view. Chrysanthemum cinerariaefolium, the species from which Pyrethrum powder is obtained, was raised from Swiss and Japanese seeds, and the flowers from plants grown in six distinct localities in England were found to possess practically the same degree of toxicity. No significant effect was apparent as the result of drying the flowers by artificial means, although it was found that prolonged exposure to wet conditions led to some loss of toxicity; contrary to general opinion, the blooms remained in good condition, when stored in a reasonable manner, for long periods.

Hurricane Damage in Germany. — The hurricane which occurred in the Münster district of Germany in the second half of the month of November did considerable damage to nursery property, the total loss being estimated at 5,000 Rm., which was, however, covered by insurance. The damage consisted chiefly of broken glass, but the tremendous floods which followed the storm put several of the nurseries temporarily completely under water.

Horticultural Examinations, 1929.—Candidates for the examinations of the Royal Horticultural Society are reminded that the closing dates for entries for the 1929 examinations are as follows:—General Examination (Seniors and Juniors), January 14, 1929; Teachers' Examination (Preliminary and Advanced), January 14, 1929; National Diploma in Horticulture (Preliminary and Final), February 1, 1929; Scholarship Examination, March 30, 1929. Entry forms and full particulars may be obtained from The Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1.

Rose Trees and the Merchandise Marks Act, 1926.—The Report on Rose trees made by the Standing Committee set up by the Minister of Agriculture and Fisheries, the Secretary of State for the Home Department, and the Secretary of State for Scotland, acting jointly, has now been presented. Copies of the Report are obtainable through any bookseller or directly from His Majesty's Stationery Office, Adastral House, Kingsway, London, W.C.2, and branches.

Plant Importations into the United States.—Interesting statistics with regard to the importation of plants into the United States of America during the past year, were published recently in an American contemporary. The total importations of Roses in 1928 was 10,505,436, a decline of approximately 1,500,000. More than half of these Rose plants were from Holland, *i.e.*, 5,767,680; 2,941,450 were from England, 1,655,800 from France, 115,500 from Ireland and 25,000 from Scotland. 242,046,763 bulbs were imported, an increase of more than

37,000,000 over the preceding year. Importations of bulbs from Holland totalled 198,510,756; Lily bulbs to the total of 17,700,424 were received from Japan; 23,425,008 bulbs came from Germany; 1,169,076 Lilies from Bermuda and 1,077,101 bulbs from France. Importations of plants under special permit were, with the exception of the fiscal year 1927, greater than in any year since 1920, the total number of plants imported under this arrangement being 24,643,420. The greatest single item of importation was Narcissus, of which 15,869,180 bulbs were received; bulbous Irises were next with 6,349,134, while other items were Gladioli, 1,598,697; rhizomatous Irises, 8,069; Paeonies, 24,521; Roses, 9,460; herbaceous plants, 54,177; and fruit trees and small fruits, 2,615. During the last fiscal year 30,035 shipments of plants and bulbs were inspected under the Quarantine Restriction Acts; 29,854 were permitted entry under permit, and 181 were refused. A total of 16,836 interceptions of prohibited plants and plant products, from 97 different foreign countries, was made during the year; 11,886 of these interceptions were made in baggage; 1,979 in mail; 243 in cargo; 906 in ships' stores; 1,092 in quarters; and 729 at appraisers' stores. In all these instances the material was actually seized and destroyed.

Imported Tomatos.—It is announced that an application for an Order in Council under the Merchandise Marks Act, 1926, to require the marking of imported Tomatos in their fresh or raw state with an indication of origin, has been referred for enquiry to the Standing Committee set up under the Act by the Minister of Agriculture and Fisheries, the Secretary of State for the Home Department, and the Secretary of State for Scotland, acting jointly. Attention is called to the fact that, under the provisions of the Act, while the Committee in every case referred to them must consider whether the goods should bear the indication of origin at the time of sale or exposure for sale, they may also, at their discretion, consider and report upon the question whether such goods should bear an indication of origin at the time of importation. The date of the enquiry will be announced later. Any communication with regard to the matter should, however, be addressed, as early as possible, to Mr. H. J. Johns, the Secretary of the Standing Committee, 10, Whitehall Place, London, S.W.1.

Massachusetts Society Medal Awards.—Following upon the announcement that the George Robert White Medal of Honour had been awarded by this Society to Colonel William Boyce Thompson, is the report that the Jackson Dawson Memorial Medal has been awarded to Mr. T. D. Hatfield, Superintendent of the Walter Hunnewell Estate, Wellesley, Mass., "for his skill in originating and propagating hardy wooded plants," and the Thomas Roland Medal to Mr. E. G. Hill, Richmond, Ind., "for his skill in originating and cultivating Roses."

Scottish Seed-testing and Plant Registration Station.—A report dealing with the work of this institution at East Craigs, in the vicinity of Edinburgh, was issued last week by the Board of Agriculture for Scotland. The premises, which were occupied in May, 1925, consist of three laboratories with glasshouses, and after describing in detail the equipment and apparatus, the limited usefulness of seed-testing in so far as the agriculturist is concerned, is discussed. Without deprecating the great advantage that the practice of seed-testing has been to agriculturists, seed producers and seed consumers alike, it must be stated that the adoption of the principle of seed control by the international seed trade has been, in some respects, to the detriment of advance. This is particularly so with reference to consuming areas. A control station cannot certify (at least, generally not with certainty) variety or strain, and it is fairly obvious that the value of purest seeds of the highest germinating quality is tempered by the capacity of its ultimate product for acclimatisation. In a country such as this the question of strain should certainly outweigh considerations at least of purity, having regard to the high perfection of the handling and marketing of seeds as now established. During the season 1925-26, the number of samples tested for purity and germination was 8,279, while reports issued on samples numbered in all 18,716. During 1926-27, 8,131 samples were submitted for testing. The second part of the report deals with plant registration. Experiments carried out in connection with Wart disease in Potatos, and efforts made to achieve immunity in certain varieties, are referred to at length, and it is stated that the great impetus given to the improvement of the Potato by these efforts is shown most notably in the attention paid to the maintenance of pure stocks of varieties and in the encouragement of Potato breeding. In conclusion, the report mentions that the station deals with a considerable number of miscellaneous queries pertaining to all branches of agricultural botany and entomology. For the most part these enquiries relate to the identification of varieties of the Potato and of Potato diseases, identification of plants and seeds, identification of treatment of plant diseases in general, and general advice regarding Potatos and seeds.

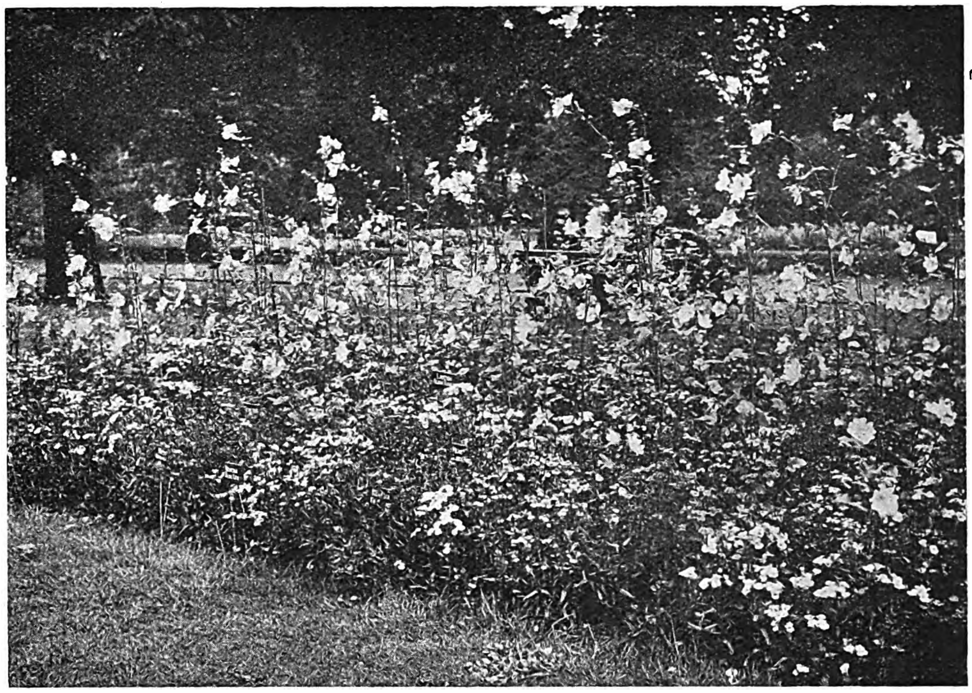

FIG. 1.—LAVATERA OLBIA AT REGENT'S PARK, WITH A GROUNDWORK OF NEMESIAS.
(see p. 9.)

An Introduced Capsid Injurious to Orchids.—Under this heading, a description is given in *The Entomologists' Monthly Magazine*, by C. C. Gimingham, B.Sc., of the capsid bug Tenthecoris bicolor, some specimens of which were found recently on a consignment of Orchids imported into this country from Brazil, and were sent to the Plant Pathological Laboratory of the Ministry of Agriculture, at Harpenden, Hertfordshire. This insect has, apparently, long been known in connection with Orchids imported into Europe; its appearance in France was reported in *The Gardeners' Chronicle* in 1908 (Vol. XLIII, Fig. 142, p. 313), while there are also records of its appearance in Germany. It has not infrequently been introduced into the United States from Brazil, Colombia and Venezuela. Mr. Gimingham suggests that it is quite a common pest of Orchids in South America, and in view of its recent appearance in this country he warns growers to look with suspicion on "any introduced insect living on a cultivated plant." He also suggests that this capsid bug may already be established in Orchid houses in this country, and he would be glad to be informed if any cases of its occurrence are noted.

Appointments for the Ensuing Week.—TUESDAY, JANUARY 8: Jersey Gardeners' Society meets. WEDNESDAY, JANUARY 9: National Carnation and Picotee Society meets; Wimbledon Gardeners' and District Mutual Improvement Society meets. FRIDAY, JANUARY 11: R.H.S. of Ireland meets. SATURDAY, JANUARY 12: Leeds Paxton Society meets.

"Gardeners' Chronicle" Seventy-five Years Ago.—*A Hard Continued Old-fashioned Frost.*—A frost that men of all ages of life declare "reminds them of their boyhood," has brought in the new year radiant with promise to the farmer of a cycle of more propitious seasons than he has of late for several years experienced. But mankind are not all farmers, nor the most inveterate farmers always on the farming topic; and viewed in other than the agricultural light, what a year has just opened upon us! Men verging on middle life are too young to realise the features that lower over the coming twelve months—and who shall say how many more?—with the prospect of another European and more than European war. It would not be easy to exaggerate the consequences that stand threateningly poised upon the moment when we have just turned from the old to the new year; a moment from which the view spreads back over nearly forty years of a Peace that had antiquated the very name of War amongst civilised countries, while before it lies an embroilment spreading like an Eastern pestilence, and enveloping nation after nation in its progress. It is impossible at a moment of suspense so circumstanced as that which this opening year brings with it not to feel a temporary lull of interest in every other less exciting topic, and to reflect with wonder on the mysterious power of evil to intercept and check the progress of good, and to compel even Peace to arm itself for Justice, to plunge into a calamitous struggle, after every unavailing effort to avert it, and to encounter a future whose probable vicissitudes baffle all foresight and conjecture. *Gard. Chron., January 7, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Seedlings.—Where a compact house can be devoted to the growing of Orchid seedlings requiring a warm temperature, the products of several genera may be accommodated and their requirements maintained more easily; otherwise, a moist position in the warm house should be set aside for them. A mean temperature of 65° is required, and humid conditions, so that the plants may be kept growing and receive no check. All the available light should be allowed to reach them at this season, therefore the roof-glass should be cleaned each time it becomes dirty; in smoky districts this occurs frequently during the winter months. The house should be vapourised occasionally to keep thrips in check; for if these pests gain a hold on the small plants considerable damage may soon be done, and the pests are difficult to eradicate if allowed to remain long undisturbed. Such neglect necessitates the rather slow and tedious work of removing the thrips with a weak nicotine solution applied with a small brush or feather, care being taken to prevent the solution coming into contact with the compost, which it will quickly turn sour at this season. Where a number of seedlings have been raised and are being grown on, there are always some plants requiring attention. With the prospect of more daylight in the near future, the present is a good time to commence re-potting any seedlings that require it, particularly Cypripediums that are in store pots and are large enough for potting singly in two-inch pots. Those that need larger pots, or where the compost has become sour, should be potted according to the size and strength of each plant, allowing a slight increase in the size of the pot each time up to the flowering size—four inches to four-and-a-half inches. A suitable rooting medium is two parts of A.1. fibre and one part Sphagnum-moss for the smaller plants, with one part fibrous loam added for plants of the green-leaved section when large enough for placing in three-inch pots, adding crushed crocks to keep the compost porous. The tessellated-leaved section do not require any loam in the compost. Cattleyas and allied subjects should be potted on when necessary in a compost consisting of three parts Osmunda or A.1. fibre and one part Sphagnum-moss, while Dendrobium seedlings may be treated in a similar manner as growth commences, but over-potting should be avoided; quite small pots or pans will accommodate Dendrobiums up to the flowering stage, while in all cases good drainage is necessary and firm potting essential. Careful watering is necessary for some weeks, to avoid saturation, but sufficient moisture should be afforded to encourage root action, while lightly spraying the plants and their surroundings on all favourable occasions is beneficial. Water should always be afforded the plants at a slightly higher temperature than the mean temperature of the house—an important point when rain-water is stored in tanks below the ground level. Water containing much lime is not suitable for the majority of Orchids, as it quickly kills the living Sphagnum-moss, and also often causes the compost to become sour.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Perpetual-flowering Carnations.—These may be propagated successfully during several months of the year, but cuttings taken during the next few weeks will be found to root more readily than those inserted at a later date. When selecting cuttings of perpetual-flowering Carnations choose those of medium size and near the base of the the flowering stem; make the cuttings by removing each selected side-growth with a heel. Insert the cuttings firmly in sandy soil; they should soon make roots if placed in propagating frames in a temperature of 50° to 55°. Remove the frames entirely every morning for a short time, to allow the condensed moisture to escape. Some growers favour rooting the cuttings in pure sand and in a higher temperature than that recommended above, but I prefer to root them in equal parts of soil and sand. Plants propagated last month are now ready for placing singly in small pots, using a light sandy soil, which should not be made too firm at this stage. After potting, stand the young plants on a moderately moist stage, so near the roof-glass as possible; under such conditions the roots will require very little water until they become more active. The temperature at this period should be as near 55° as possible, and as much air should be admitted through the top ventilators as the outside conditions will allow.

The Seed List.—If the order for seeds has not yet been placed with the seedsman, no time should be lost in doing so. There are several useful flowering subjects that will need sowing towards the end of the present month, notably Gloxinias, Streptocarpus, Begonias and an early batch of Clerodendron fallax.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—The majority of growers introduce their first batch of Strawberry plants to a little gentle heat at the beginning of the New Year. A little sweet, moist heat from fermenting leaves in a pit is, perhaps, the best medium in which to start the plants, as the gentle warmth thus provided stimulates root action before top growth commences. Unless we experience a complete change in the weather, little or no artificial heat will be necessary, as 40° to 45°, with a slight rise during the day, is all that is needed for the present. A slight check by frost would do the plants good; if this occurs, the pots should be protected by being plunged to the rims in ashes. Remove the plants, so soon as they approach the flowering stage, to a shelf in the lightest part of the Strawberry house, so that fresh air may circulate freely among them. Pollenate these early flowers with a brush at midday, when the pollen is dry and a little air is being admitted.

Cucumbers.—The next two months are the most difficult in which to maintain an unbroken supply of Cucumbers. Keep the plants trained thinly, crop them only moderately, and lightly top-dress the roots with warm compost whenever they appear on the surface. Encourage growth by occasional waterings with warm, weak liquid manure, and light sprinklings of the same on the paths and borders. Sow fresh seeds in small pots, and place them in a bottom-heat of 75° to 80°, removing the seedlings, so soon as they are well through the soil, to a light position in a temperature of 68° to 70°. Cleanse the house for the reception of these plants, and prepare the materials for providing bottom heat, *i.e.*, litter and leaves, so that all may be in readiness by the time the plants are ready for planting.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Preparation.—The arrangement of the flower garden calls for considerable forethought on the part of the enthusiastic gardener. The beginning of the New Year, with its long evenings, is a suitable time to review the successes and failures of the previous season's work and to lay plans for the coming summer display. The wise man will have made numerous notes on the results of his own work, and also of the various bedding schemes that have come under his observation while visiting other gardens and public parks throughout the year. Now is the time to prepare from these notes, so far as possible, the scheme of planting for the coming season.

Flowers from Seeds.—Look through the stock of seeds in hand and put them in proper order for sowing as required; obtain, so soon as possible, those necessary to complete the season's requirements. Nothing is more annoying to the gardener than to find that the seeds are not at hand when required. Therefore be advised to order your supplies early and, as good seeds are cheapest in the end, always buy from a house of repute.

The Rock Garden.—The removal of decaying leaves should receive constant attention, as these gather in the recesses and soon spoil valuable plants. New growth is beginning to show in some sheltered corners, and it behoves the ardent alpine gardener to be on the look-out to see that nothing interferes with his treasures. At Wisley, the beautiful Primula Winteri has been in bloom since early November. Planted near the base of a rocky ledge, facing nearly due north, where it gets abundance of moisture at its roots during summer and sufficient protection by slightly projecting rocks to shed the rain off its crowns, this charming plant flowers earlier in the open than in the alpine house. Many growers fail with this subject through planting it in a position where the plant does not receive sufficient moisture at the roots during the heat of the summer. If planted beneath slightly projecting rocks, these will protect the resting buds and also the blooms from autumn and winter rains.

Heaths.—Those who only know a few of the commoner varieties of this extensive family and who, in these days of labour shortage, desire to know what to plant to give a long season of bloom with little upkeep, might profitably make greater use of Heaths on soils that are free from lime. Even on soils containing lime such varieties as Erica carnea, E. c. King George, E. c. Vivelii, E. c. Pink Beauty, E. c. Queen Mary, E. c. Prince of Wales, E. darleyensis and numerous other hybrids belonging to this group, will grow well. Many of these are in flower in the Heath garden at Wisley at the time of writing, and should continue to brighten this part of the garden for many weeks. These will be followed by groups of E. mediterranea, E. m. Brightness, E. m. alba, E. m. superba, E. arborea, E. australis and others during early spring. Heaths may be transplanted easily, and when once established the work of upkeep is almost negligible. Trimming the clumps with a pair of shears to remove the decaying flower heads and to keep the plants from becoming straggly is all that is required.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Spraying.—It is generally advocated that the winter spraying of fruit trees should be left so late as possible in the season, and where the necessary labour and machinery are available and can be employed at the precise moment, that is sound advice. There are few gardens at the moment, however, where there is a surplus of labour; while in our variable climate favourable conditions are not of daily occurrence. Indeed, during the next eight weeks, when this important work should be completed, we shall be fortunate if one ideal day a week occurs. It is essential, therefore, that all preparations be made in advance by overhauling the spraying machines and hose, so that, if spare parts or additions are required, there is a margin of time for delivery before spraying becomes urgent. It is of equal importance, too, that all spraying material is at hand the moment it is needed, and a spraying plan drawn up. The following may prove helpful in arriving at an estimate of the materials required. Trees with a spread of ten feet will require two gallons of diluted spray per tree; those with a spread of twenty feet may require five gallons of diluted spray to be effective.

Winter Washes.—If a few of the fungicides and insecticides, employed as washes on dormant trees, and their respective dilutions of water, are considered, a fair estimate of requirements may be obtained. Lime-sulphur is, at the present time, the most popular all-round fungicide for winter work. When used at winter strength, *i.e.*, five per cent., it is most efficacious against Apple and Plum blossom wilt, Apple brown rot, mildew, scab, canker (in conjunction with other measures), Plum leaf-rust, and American Gooseberry mildew. When employed against Black Currant mite, however, the strength should be a little over eight per cent. or, roughly, one part in twelve. Ammonium polysulphide is another popular fungicide, and has a great advantage in that soft soap and nicotine can be mixed with it, so serving the dual purpose of insecticide and fungicide. It is, however, best employed as a spray when the fruit trees are in leaf, and it is particularly useful for spraying Gooseberry bushes in early summer against American Gooseberry mildew, as this spray leaves no deposit on the berries. The usual strength is one per cent., with the addition of 5 lbs. of soft soap to every one hundred gallons of water, to improve its wetting and penetrating qualities. The various tar-distillates differ very little from each other. They are most effective in destroying aphis eggs, and when used at five per cent. make most economical winter washes. Lime, when used as a cover wash just before the buds burst, is considered by some to be the most efficacious egg-destroying wash we have. It must, however, be made from the very best shell lime. It should be used at the strength of 2 lbs. to the gallon, or 2 cwt. to one hundred gallons of water. It is a most powerful cleanser and does not dry out or bind the bark of fruit trees like caustic alkali. Employed at the proper time, it is one of the best preventives of Apple sucker. The shell lime should be kept perfectly dry and air-tight until required for use.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Vacant Ground.—Where ground has to be dug, manure should be wheeled on to it and the ground turned over without delay. Soil that was heavily manured last year for deep-rooting vegetables will not require any this year, smaller vegetables, such as Lettuces, stump-rooted Carrots, Turnip-rooted Beet, etc., being suitable to grow on it.

Store Potatos.—On wet days the Potato tubers in store should be sorted, removing any that are decayed, or the sound ones may soon become infected. Place plenty of straw over them to exclude frost. Early seed Potatos for forcing should be placed in boxes and brought out into the light for sprouting.

Globe Artichokes.—A mulching of leaves or manure, or ashes, should be placed around the collars of Globe Artichokes to protect them from frost. Globe Artichokes die down early in the autumn and at this time of the year are always green with leaves. When a severe frost comes along they are liable to be badly crippled; therefore a mulching often proves of assistance.

Vegetables in Frames.—Where Lettuces and Endives are growing in frames, air should be admitted freely on bright days. Keep the plants free from weeds and at intervals stir the surface of the soil. Water them sparingly, and remove any decaying leaves.

Onions.—Where specimen Onions are required seeds should be sown now in boxes, in a compost of good loam, leaf-mould and sand. Put plenty of rough material at the bottom of the boxes for drainage, and place the boxes in a warm house. Good varieties are Ailsa Craig, Cranston and Premier. The ground for these Onions should be enriched, plenty of cow manure being incorporated. Leave the surface as rough as possible so that the frost may pulverise it. Before digging, a dressing of Vaporite, distributed evenly over the ground, should be beneficial to the crop later on.

Seakale.—More crowns of Seakale should be placed in the forcing house, and root cuttings prepared for planting in spring. These should be placed in ashes, crown-end uppermost, to encourage the formation of eyes.

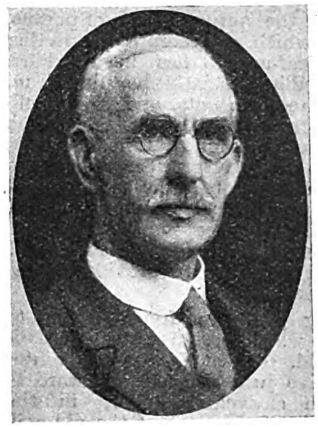
FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Plants in Frames.—Sweet Peas, Violets, cuttings of rock plants, and all other subjects in frames, should be attended to carefully; admit air freely, remove the lights on all dry, mild days, and even during slight frost admit a little air. In severe frosty weather keep the frames closed until a natural thaw sets in. Remove any decayed leaves from the plants and, if water is required, apply it early in the day during bright weather.

Clarkia and Schizanthus.—Keep both of these subjects dwarf by pinching out the growing points regularly until the days lengthen, when more satisfactory and firmer growths will be made. Do not allow them to become potbound, but avoid large shifts at present. One of the chief causes of failure in these soft-growthed plants is drought. If once the compost becomes dry the fine feeding roots perish, and the plants are not able to absorb water when it is applied, and consequently damp off at once.

Pruning and Training Wall Trees.—This work should be pushed on with all speed. Cherries, Plums and Peaches should be dealt with on the extension system in its fullest sense. If the growths are well-ripened, they should be laid in full length up to about eighteen inches, while if the leaders have to be cut back, they should be shortened to a bud facing the wall; in every case the growths should be fastened firmly to the wall. This gives a better lead than if cut back to a bud facing outwards, as is generally done. Lay in young shoots all over the trees to take the place of old, worn-out branches. If the trees have been neglected in this respect, remove a few branches to make room for young growths to be laid in during the coming season. Apples and Pears may also be grown well on the extension system, but it is not so necessary as with stone fruits. Provided the old spurs are removed, a few each year, the trees may be kept in healthy condition. When this work is finished spray the trees with a winter wash.



Carnations.—If the required number of cuttings of perpetual-flowering Carnations has not been inserted, no time should be lost in getting them in. A bed of sharp sand, in a box or case over the hot-water pipes, is ideal for them. Make the sand firm and insert the cuttings just deep enough to hold them erect. Side-shoots half-way up the flowering stems are best; they should be pulled off with a heel and the tail removed with a sharp knife. Water them in and cover them with glass for the first week or so, turning the glass each morning, after which they may gradually be inured to full exposure.

Asparagus.—The difficulty attached to growing this vegetable lies in establishing the plants after transplanting, but it is quite easy to avoid this by sowing the seeds in the permanent beds. In the meantime, the ground should be prepared. If it is of a clayey nature, sand, burnt soil and any other opening material should be added, and the ground trenched at least two feet deep, breaking up the subsoil as the work proceeds, and adding plenty of good manure or sea-weed to it. Horse manure is best for this type of soil. Leave the surface as rough as possible until sowing time, which will be in March or April. On light soils, deep trenching may be resorted to, adding liberal dressings of cow manure.

INDOOR PLANTS.

AMPHICOMES.

I HAVE searched in vain through a great many seed and plant catalogues, but nowhere can I find a reference to the most beautiful of the two species of this genus. I refer to Amphicome Emodi, with its remarkably handsome, trumpet-shaped flowers, which have large rose-colooured corollas, and bright orange-tinted throats. A large number of these showy flowers are produced on each plant, and as they are carried in an upright position the plants, when in flower, bear some resemblance to the Gloxinia. The only other species, A. arguta, is of a more graceful habit, the smaller, reddish-pink flowers being produced on slender branches. However, they are both worth growing, and nurserymen would be well advised to include the names of these plants in their catalogues, because, being natives of the Himalayas, they are almost hardy, and only require the protection of a slightly heated greenhouse to bring them safely through the winter.

The seeds are rather curious in structure, having a tuft of hairs at each end, and it is from this unusual feature that the generic name has been derived; *amphi*, meaning both sides, and *koma*, a head of hairs.

These half-hardy perennial herbs belong to the Bignoniaceae, and are closely allied to the Incarvilleas, which A. Emodi closely resembles.

These plants may be raised from seeds, which should be sown in the spring, in pots of porous, sandy loam, to which a generous proportion of finely-sifted leaf-mould has been added. The resulting seedlings should be potted up separately into three-inch pots, and when well-rooted in these, transferred to five-inch, which size will be large enough for A. Emodi, but A. arguta, being a stronger grower, requires a further shift to enable it to grow to its fullest extent. The compost for potting should consist of equal parts of loam, leaf-mould and well-decayed manure, and during the summer months a cold frame will be found to provide all the protection that they require.

Their flowering period is from August to September, after which period water must be gradually withheld, so that during the winter they should receive just sufficient moisture to keep them from shrivelling. Early in the spring they may be shaken out of the old soil, repotted, and restarted into growth to provide flowers for another season. *G. F. Gardiner, University Gardens, Bristol.*

EXACUM MACRANTHUM.

THE note upon Exacum affine, on page 408, Vol. LXXXIV, of *The Gardeners' Chronicle*, by Mr. L. G. Atkins, contains all the necessary details requisite to cultivate this E. macranthum successfully, and, if adhered to, no difficulty need be experienced, and the results will prove all that is claimed for this charming plant.

Exacum macranthum is quite distinct from E. affine, and surpasses it in every way in point of beauty. It has large, bright violet-blue flowers, nearly two inches in diameter, with conspicuous yellow stamens, produced in corymbose heads upon the terminal and axillary branchlets; it is a most attractive plant, and the flowers are borne no less freely than with E. affine, upon specimens eighteen inches to two feet in height. E. macranthum seems to be a rare plant in gardens at the present time, a condition attributable, doubtless, to the fact that it does not respond so readily to culture, and with the same freedom, as do many favourite indoor plants; perhaps the error of depending wholly upon late winter and early spring sowing of seeds, with the resultant failure of germination, is partly responsible for this plant remaining uncommon.

While perusing a seed catalogue of a well-known firm, I noticed seeds of Exacum macranthum listed therein, but I would advise sowing the extremely minute seeds of E. macranthum in early August with a view to obtaining strong, well-established young plants to winter near the roof glass, in a warm house with a temperature under normal conditions, not falling lower than 60°.

The compost should consist of equal parts fibrous loam and peat, with a liberal admixture of coarse sand and small granulated charcoal. Single plants may be potted finally into fifty-four or forty-eight-sized pots, or three plants may be accommodated in thirty-two- or twenty-four-sized receptacles. I do not usually advocate growing several plants in one pot, but Exacums lend themselves to such practice without detracting from their appearance.

During the period of growth the plants should be accommodated in a warm greenhouse, removing them to the flowering house when they commence to bloom. *Frederick Gooch.*

AZALEA INDICA IN JAPAN.

ALTHOUGH one of the early introduced species, and familiar in Europe, Azalea indica has little to connect it with India, except its misgiven name. The wild plants are occasionally found growing on the cliffs near a stream, but Azaleas are planted freely in Japanese gardens, where they form roundish bushes and produce an abundance of blossom in early June. This lustrous, small-leaved evergreen shrub is also much appreciated as a pot plant.

There are many garden forms. Among the recent introductions, the following are worth mention: Rinpo, brick-red, with white throat, many-petalled; Koraku, fine purplish-pink, one of the best; Hao, white, spotted with purple; Ranpo, purple with white throat—one of the parents is Koraku; and Shirosumi, greenish-white, very narrow petals.

An Azalea (now Rhododendron) indica specimen with which I am familiar is some twelve years old from the cutting. It is sixty-eight centimetres in width and forty-six centimetres in height. The owner paid 2s. 10d. for it last autumn, but the ordinary price for this size is about 5s. Plants twenty centimetres in height and one hundred centimetres in circumference are 2½d. each for the average kind, and the trade price is much lower than that. This will give some idea of the price of this Azalea in Japan.

Early in June this year, I went to collect a Gentiana in a village about twelve miles from my home, where a farmer buttonholed me, and asked me to see his fine Azalea indica. It was fine, although the flowers were over; the plant was five feet in height, and covered nearly four square yards. "Some days ago," the farmer said, "it was smothered with fine, brick-red flowers from the bottom to the top." When I was measuring the specimen, he added "If you like the plant, I will sell it for six shillings!"

Japanese nurserymen used to propagate Azaleas by cuttings, in the field, and four-year-old plants are good enough to sell in the market. *K. Yashiroda, Japan.*

ALPINE GARDEN.

ERYSIMUM LINIFOLIUM.

CRUCIFERS of the Wallflower persuasion are apt to be precocious in flowering, but few of them bloom so persistently here as this Spanish and Portuguese species. In spite of some sharp frosts, many plants of E. linifolium were carrying quite a number of blossoms during the Christmas season, and I much doubt whether there is any single week of the year in which it is not showing some colour. This, however, is not a hardy species. It was practically all killed here during the winter of 1927-28, only a few seedlings in very sheltered crevices surviving. Even so, E. linifolium is one of those generally useful plants which must always be replaced. Not only is it compact in habit and adaptable for all sorts of situations, from a dry wall or fissure in the rock garden to the front of the border, but its lavender-purple flowers are a delightful shade. They are blue enough to blend most happily with the yellows of spring and purple enough to be in sympathy with the more sombre tones of later days.

Although E. linifolium is so generally useful, it is seldom so charming as when on a wall or against the face of a rock. In such a position, the soil being of the poorest description, it does not get much above six inches or so in height, and grows hard and wiry, pressing its branches flat against the stones. It is, of course, an ardent sun-lover, and perennial. But if it is not long-lived it usually provides plenty of self-sown seedlings. The leaves of E. linifolium are narrow and pointed, widely-toothed, undulated at the margins and of a dull bluish-green. It would appear, however, that there are several forms of this plant in cultivation other than the dense little alpine form, E. l. filifolium, which I have heard of and have never been able to secure. In this regard, I may say that several new plants of E. linifolium, which flowered last year, have leaves which are broader and thinner in texture, as well as a fresher, more grassy-green, than those of my original stock. The lush leafage of these newcomers does not suggest that saxatile nature which is so obvious in the, to me, better-known plant.

LINUM SALSOLOIDES VAR. NANUM.

A GOOD form of Linum salsoloides, with large flowers and a moderate stature of about eight inches, is a very lovely plant, and one that asks but the meanest of sun-beaten soils. But L. s. nanum, which is a development of this species, with a perfectly prostrate habit, is even more attractive. This charming subject makes an exceedingly close, ground-hugging mat of wiry branches, which are densely clothed with an exceedingly fine, almost fur-like foliage in a cool, glaucous-green. In summer, this emerald carpet is studded with pearl-white flowers, flushed with purple at the base of the corolla. They are almost stemless, and so beautiful is the texture of these shell-like vases that at first sight they may suggest the lovely blooms of Oxalis enneaphylla on a reduced scale. L. s. nanum would be worth a place for its foliage alone.

I find it hardy and permanent on a gently-sloping ledge of really poor, stony soil, and since it is a haunter of some of the hottest places of the southern Alps, it should be given all possible sun, and in some districts would be the better for a pane of glass tilted over it during winter. It strikes readily from cuttings, short growths about an inch long being inserted in very sandy soil and plaœed in a cold frame in August. This is essentially a plant for a close-up position in the rock garden, and an ideal subject for stone sinks or pig-troughs.

POTENTILLA NITIDA.

THE rock-gardener who can grow Potentilla nitida really well might claim to have attained an enviable measure of success. For if not tender, or even difficult, this species, when in our gardens, seldom impresses one with that robust loveliness with which it adorns its native Alps. Moreover, achieving such an object with P. nitida is equivalent to having succeeded with one of the most beautiful of European, perhaps of all, rock plants. The native home of this Potentilla is upon the higher altitudes of the limestone formations of the Tyrol and northern Italy, where it grows, for the most part, in rubble or débris drifts. It is a plant with a woody base and a prostrate, creeping habit, rarely attaining above two inches in height. The rather narrow leaflets of the Clover-like leaves are a grey-green on the upper surfaces, with a silvery reverse. In fact, the whole mat has a silvery effect, especially in winter and spring. The flowers, which usually appear in June (nearly two months earlier than in the Alps) are about the size of a florin and of an exquisite shell-pink, suggesting little Dog Roses, with a darker centre. Surpassingly lovely as they are in themselves, these blossoms are rendered the more enthralling by their setting, P. nitida having discovered the subtle charm of a blend of satin-rose and silvery-grey.

Although P. nitida is hardy, and not even very resentful towards our winter rains, it does not always flower so freely in our gardens as one would wish, and therein lies the primary difficulty in its cultivation. For some years I have had it in a dry moraine, and this seems to suit it, since it blooms with a greater heartiness than ever it did under other conditions. Lime in some form is probably essential, but thorough drainage and—failing moraine treatment—a root-run in a compost mainly composed of rubble and grit, are essentials. Full sun it must also have and a piece of glass to throw off the worst of the wet does not come amiss.

There are several colour forms of P. nitida. These include varieties with flowers of various shades, darker and lighter than the type, and there is a good white. But I do not think any of them are so delightful as the fresh, clear pink of the typical species. Propagation may be carried out by striking cuttings in pots of very sandy soil in a cold frame during the later summer. *North Wales.*

TREES AND SHRUBS.

RHODODENDRON HIPPOPHAEOIDES.

Among the many species belonging to the Lapponicum series of Rhododendrons introduced during recent years, none is more suitable for garden culture than R. hippophaeoides (Fig. 2), which, despite its rather cumbersome name, is free-growing, free-flowering and of good constitution.

It was first discovered by Captain F. Kingdon Ward in the spring of 1913, in north-west Yunnan, China, but it was through Mr. George Forrest that this beautiful Rhododendron found its way into our gardens, as later on in the same year he collected seeds of it. It is found at an altitude of 11,000 feet, growing in association with ten or more other members of the Lapponicum series, and as it is fairly widely distributed, the conditions under which it grows naturally are varied—it is found in open Pine forest, marshy meadows, boggy, peaty meadows and open, moist, stony pastures, while Handel-Mazzetti, one of the leading authorities on the Chinese flora, describes it as growing in what he terms "leaf-mould meadows," a peculiar formation consisting of deep soil, of dry, open texture, composed almost solely of decayed rhizomes and leaf-sheaths.

The flowers of R. hippophaeoides vary considerably in colour, the dominant shade being rich lavender-blue, but there are forms ranging in colour from blue and purple, through intermediate shades to rich rose or pale shell-pink.

This species has responded remarkably well to cultivation in this country. It forms a shapely bush, at present up to about three feet, but it will apparently go to four feet, and seems to delight in peaty soil of rather a sandy nature, either in open woodland, in the Heath garden, or on the rock garden—a really charming effect may be produced by planting two or three specimens against a grey boulder on the rock garden, such a background forming a very effective foil to the flowers.

It is evergreen, the glabrous, oblong or elliptic-oblong leaves, obtuse or rounded at the tips, being dark green on the upper surface and covered with yellowish scales beneath. The flowers are produced in closely-packed, terminal umbels of up to eight blooms, often so freely that the bush is transformed into a mound of colour.

Naturally, this Rhododendron is still comparatively rare in this country, but it is propagated easily by both seeds and cuttings and should soon be grown much more extensively. *F.*

EVERGREEN BARBERRIES.

For quite a considerable time, I have taken more than ordinary interest in these Barberries, and *M. W.'s* article (p. 367, Vol. XXXIV) came at an opportune time. Most of those mentioned I was well acquainted with, but there are several others of interest which may not come up to the standard of those he referred to, but which may be planted to augment a collection.

Most of these belong to the Wallichiana group, which is now highly developed, and at one time or another there has been much confusion in it, the chief characters being evergreen, flowers solitary or in fascicles, and black fruits. It is much to be regretted that the type, B. Wallichiana, appears not to be in cultivation. I often wish I could see this species growing, so as to compare it with existing species allied to it, and to prove whether it is hardy or not, or note what physical differences distinguish it from its close relatives. I always imagine B. Julianae to be nearest to it. I presume that B. Hookeri is the best-known of the Himalayan Barberries, but there is considerable difference between it and its variety viridis, the latter being quite green on both sides of the leaves, whereas those of B. Hookeri are decidedly glaucous on the under-surface. Both produce plenty of berries, are compact in growth, and attain three or four feet in height. B. Hookeri var. latifolia, on the other hand, which might be termed an enlarged B. H. var. viridis, never seems to fruit freely, although I do not know why this is so.

B. Julianae is a Chinese species which is even stronger than the last-named, from which it differs by having larger, dark green, glossy leaves and narrow, pruinose fruits, not stout as in the previous species. So far it has proved quite hardy, except when in flower, the blossoms being produced in early spring and therefore often caught by late frosts; it has more fruits this winter than hitherto seen. B. candidula, which is now fairly well-known, has a neat habit and keeps within bounds, being two to three feet high, with dark green foliage, glaucous beneath; I have never seen it really floriferous or in fruit, not even in adult bushes; nevertheless, it is a most useful evergreen.

I can endorse almost all that has been written concerning B. replicata. It is a most distinct species, each year the previous season's shoots being almost completely clad with flowers, which do not, however, always escape damage by frosts. Even now the winter buds are disclosing the inflorescence where bushes are somewhat sheltered. Last flowering season this bloomed particularly well at a period free from frosts, and I notice there are still a few small black fruits on the lowermost shoots.

Another Berberis that claims a position in any collection is B. Bergmanniae var. acanthophylla. The type does not seem to be in cultivation, and this variety has a more spinous leaf. It favours B. pruinosa in habit, but when the two are growing close to each other, the latter's foliage is seen to be paler green, and the fruits are more pruinose, and little, if any, remains of the style, whereas it is a prominent character of many of the class. Other evergreen Barberries of distinction are B. Soulieana, and B. atrocarpa, the specific difference between the two being rather remote, but easily defined on acquaintance. At present both are from six to seven feet in height.

B. Soulieana is more erect and stiffer in habit, the leaves being long and narrow, while it produces clusters of small, roundish, black fruits, which are almost white with "bloom." B. atrocarpa is more loose in habit, the foliage is smoother, and it is easily distinguished from B. Soulieana in that the fruits are fusiform in shape and smaller; they are black in colour, with little or no "bloom." Both these species have formidable spines and flower at the same time. I may merely mention that Berberis Veitchii, which at one time was named B. acuminata, is of interest because the colour of the flowers is of a different shade of yellow to all the others, with, perhaps, the exception of B. Thunbergii.

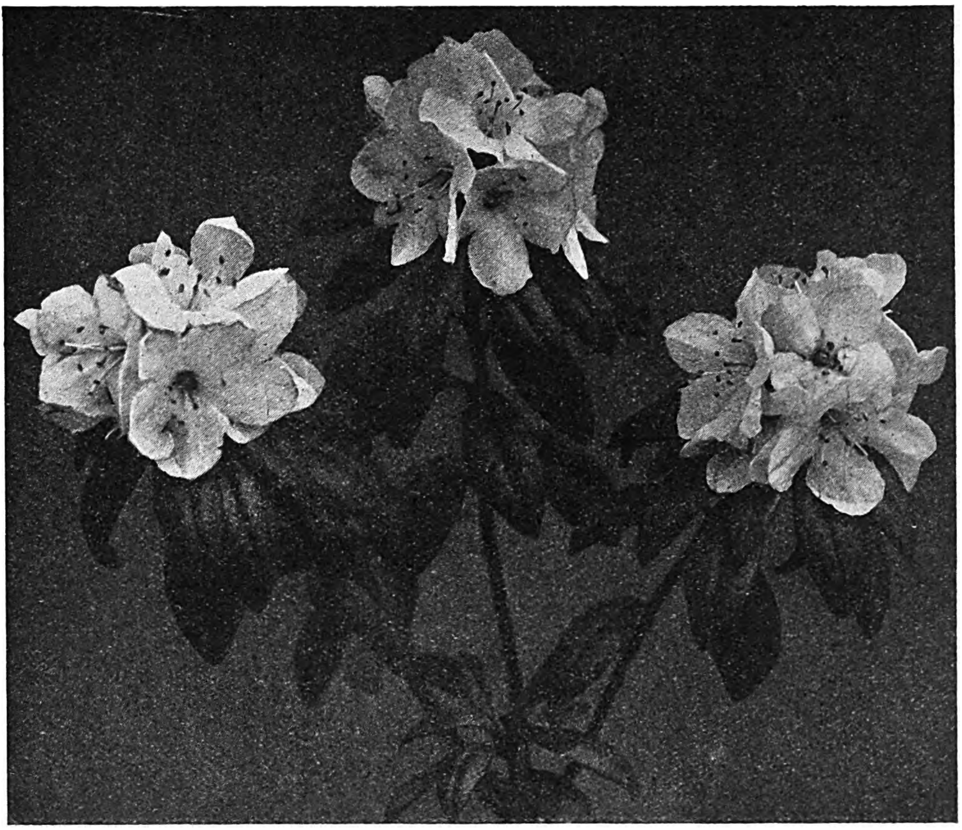


FIG. 2.—RHODODENDRON HIPPOPHAEOIDES.

Berberis sanguinea is an evergreen and of Chinese origin; its height appears to be limited to about four feet, while in habit it is dense and twiggy, the growth being short and angled, with closely placed nodes and bristling with very sharp spines of a light green colour. The leaves are distinct in character, being borne in clusters of three to six, the largest being two-and-a-half inches long, but the greater number are about one inch in length and less than a quarter-of-an-inch broad, very narrowly lanceolate in shape, wavy, and entirely margined with bristle-like spines. It flowers only moderately freely in early spring; even now the flower buds are peering through their winter coverings. They are pale yellow, with a tinge of red in the sepals and a deeper tinge to the pedicels. The fruits are purplish-black, with slight "bloom," and oval in shape, although only a few have been produced so far. The small leaves and numerous three-forked spines are a ready means of indentifying this species.

B. empetrifolia, a species from Chile, is best known in gardens as one of the parents of the well-known Berberis stenophylla. Judging it as cultivated, it is of prostrate habit, eighteen inches to two feet high, with thin growths and small, narrow leaves. It does not flower very freely and I have never seen any fruits on it; perhaps young plants grown in a warm border would do better. It would be useful in the rock garden.

I have never seen a batch of seedlings raised from B. stenophylla seeds, but have read at times how they vary, as is evident in the several forms, such as B. stenophylla var. coccinea, etc.; last September I was impressed with B. stenophylla var. autumnalis, which was in full flower at that time. Although most of the varieties take after B. stenophylla, except in height, I have never seen any comparable with B. empetrifolia.

An account of evergreen Barberries is not complete without reference to another species from Chile, namely, B. hakeoides, which at one time was B. congestiflora var. hakeoides. It is an old species, yet not so often seen as it should be. Certainly the habit of growth is lank, but it produces shoots that in time are so thickly set with flowers that there seems no chance of growth from such congestion. The round, strong, thick leaves are surrounded by sharp, evenly-placed spines. It never fails to flower well, and in spring is most conspicuous, as the young shoots made the previous season, some two feet or more in length, are literally covered with orange-yellow flowers, which are bolder at the base of the shoot and gradually diminish as they ascend to the apex. Nurserymen find it difficult to propagate, and resort to grafting it on to B. vulgaris; as proof of this I have found suckers at the base of plants.

These Barberries have, on the whole, good root-systems, and young plants transplant well if care be taken to retain a certain amount of soil. With older plants it is imperative to lift them with a good ball of soil, as they are impatient of transplanting. *C. F. C.*

CYTISUS MONSPESSULANUS.

THE Montpelier Broom, as this species is called, is a shrub of six feet to eight feet in height, with a somewhat upright, stately habit, the ends of the branches often drooping when in flower and fruit. The trifoliate leaves are a rich green and borne in great abundance. Indeed, this is one of the leafiest of the Brooms, and the foliage is evergreen even throughout hard winters. The flowers appear in May and June, and they are borne with the utmost liberality in short, axillary racemes. They are a bright yellow, about half-an-inch long and slightly fragrant. Seeds are ripened in plenty and these afford a ready means of increase by open-ground sowings in summer, but in many gardens self-sown seedlings are quite numerous enough for all requirements.

This handsome and useful Broom is a native of almost the whole of the south European coast, from Portugal to the east, and it occurs also in northern Africa and parts of western Asia. It has been cultivated for nearly two centuries, but has never been common in gardens, possibly on account of a reputation for tenderness. Regarding this, however, I must say that it has never suffered the least injury from frost here. Last winter old shrubs and seedlings were fully exposed to 24° of frost on more than one occasion and only the very young plants were slightly affected. Since this experience is quite at variance with that of Kew, where this species, according to Mr. Bean (*Trees and Shrubs Hardy in the British Isles*) succumbs to 15° to 20° of frost, it appears probable that there are strains of this shrub in cultivation which are hardier than others, and that I have got one of these. Such a suggestion does not seem improbable when one realises the vast extent of this Broom's natural range. I will add, however, that my plants are mostly growing in a meagre, rocky soil, which is undoubtedly a help. But would such conditions be sufficient to account for the fact that while G. monspessulanus does not lose a leaf through 24° of frost here, it is killed outright by a frost of less severity at Kew?

I have alluded to the above at some length because, from my own twenty years' experience of it, I feel that this is a shrub which might well be given a much wider trial. In this garden it is quite naturalised, and there are few Brooms which retain their shapeliness and vigour so long as this one, and its foliage is delightful in winter. This Broom, moreover, is one of the few which will grow from the base with vigour should it ever be necessary to cut it back.

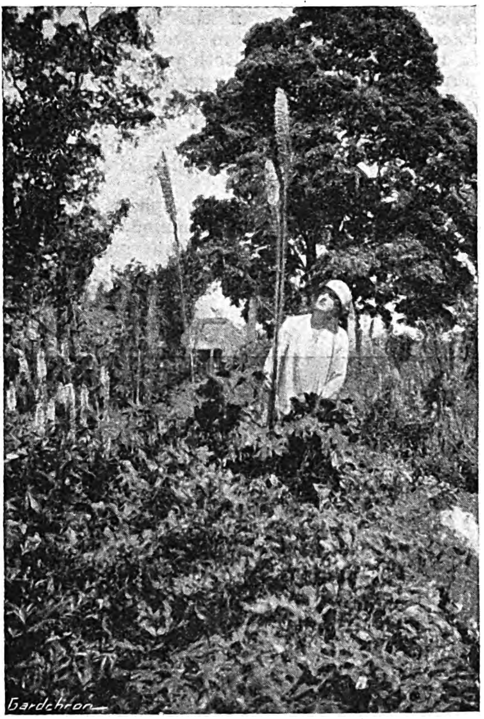

FIG. 3.—EREMURUS ROBUSTUS.

C. monspessulanus bears so close a general resemblance to C. racemosus (syn. C. fragrans) that it might well serve as an outdoor substitute for that old greenhouse favourite in any locality where the winters are not too severe, but it would be interesting to hear the experience of others regarding the hardiness of the Montpelier Broom.

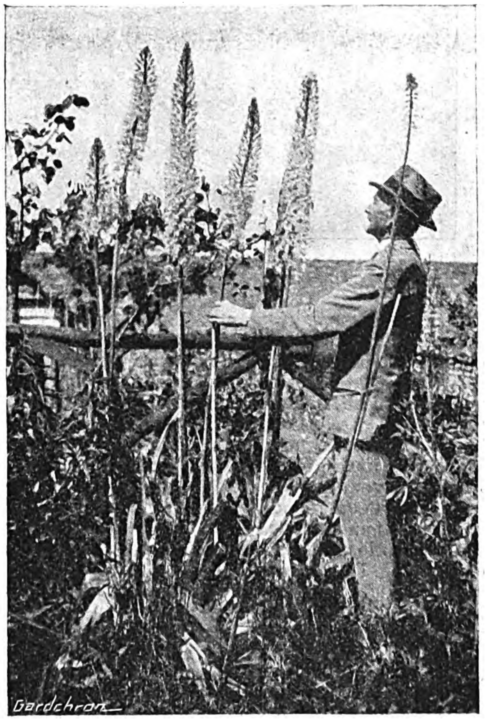

FIG. 4.—EREMURUS HIMALAICUS.

GAULTHERIA NUMMULARIOIDES.

THIS Gaultheria is always attractive in the woodland at any season, but it is especially charming in winter, when its rich green associates very happily with evergreen, hardy Ferns. It is grown here on a shady bank of light soil which is retained by stones being inset. Like so many of its race, it likes to thrust its underground shoots beneath the stones, and between the latter it makes tufts of drooping foliage which drape the entire bank with a thatch of delightful verdure. The stems of G. nummularioides are usually unbranched, and from six inches to nine inches long. They are closely furnished with a double row of alternate, rounded, heart-shaped leaves. These are nearly three-quarters-of-an-inch wide at the base of the stem, but they decrease in size towards the tips, thus giving the elegantly tapered effect familiar in the Moneywort (Lysimachia Nummularia). The growths are covered with bristles of a tawny-brown, and the pale green underparts of the leaves, as well as the margins of the latter, have these same stiff brown hairs.

The dark, green, upper surfaces of the leaves are slightly-wrinkled and convex. Although G. nummularioides flowers freely, fruits are never set here, and it would be interesting to know whether it fruits in other parts of the country and, if so, under what conditions. The small, bell-shaped corollas are not much more than one-eighth-of-an-inch across. They are greenish-white, tinted with pink, and appear singly at the leaf axils in August, hanging underneath the stems. Instead of these blooms being shed when spent, they turn a rusty-brown and remain on the growths all the winter.

G. nummularioides is a native of the Himalayas, and although long known to cultivation it has never been common in gardens. I have found it quite hardy, being uninjured by over 20° of frost, but it dislikes cutting winds and draughty corners such as it may get in the open rock garden. It may be increased by cuttings or detaching rooted pieces from established clumps. But as the plant resents such disturbance as the latter involves, none who value a well-grown patch will risk meddling with it in that manner. There is a dwarf form of the plant known as G. n. minor. I have not had it sufficiently long to be able to make any statement as to its ultimate size when fully grown, but it does not look like attaining half the dimensions of the type in stem or leaf. At first glance it might be taken for rather a pale green Spleenwort Fern (Asplenium Trichomanes) and should do well associated with the latter on shady, woodland banks. *A. T. J.*

HARDY FLOWER BORDER.

EREMURI.

IN your issue of December 22, 1928, appeared an article on Eremuri, over the signature *F. S. Banfield*. In course of his remarks, Mr. Banfield states that Eremuri are hardy only in the sheltered gardens of the south and south-west of England. In my garden here, which, I may say, is in an exposed position on high ground overlooking the city, I have grown both E. himalaicus and E. robustus for the past five years, with no special treatment, other than a covering of leaf-mould during winter, as I find their long, prong-like roots run very close to the surface. I enclose photographs (Figs. 3 and 4) showing Eremurus himalaicus in full flower, about seven feet high, and E. robustus, rather past its best, ten feet high. There are no plants in my garden which ask for or receive less attention, and yet they grow and throw up additional spikes yearly. I may also mention that with the scant protection they receive they have come safely through a winter even with the thermometer at zero. When up Deeside last summer, I saw a fine clump of Eremuri in a garden there, although it is one of the coldest districts in Scotland. While writing on this subject, I would like to add that Cortaderia conspicua forms great plants here, and withstands the hardest winters, although in the majority of nursery catalogues it is termed half-hardy. Juniperus bermudiana also stood out in the open all the winter of 1927-8, but it remains to be seen if it will continue to withstand the severe conditions. *A. W. Brown, Letham House, Perth.*

SILPHIUM PERFOLIATUM.

The Silphiums are tall plants only suitable for the wild garden or large border, as a rule; but that under notice, S. perfoliatum, the Cup Plant, looks very well indeed at the back of the border. It is not the Silphium referred to by Longfellow as the "Compass Plant," but is a much finer subject for the garden than the poet's plant. It derives its specific and popular names from the arrangement of the foliage, which is perfoliate, the leaves forming a receptacle which holds water for some time. S. perfoliatum grows from four to eight feet high, and to ensure that the plants reach the latter height, when they are more decorative, a deeply-dug, rich, and well-manured loam, not too dry, should be provided for them. When well-grown, S. perfoliatum is quite a handsome subject with its yellowish leaves, eight to twelve inches long, and flowers about two inches across. Although a good soil is to be recommended, this Silphium will grow and flower in even poor clay soils. It may be raised from seeds or increased by division in spring.

S. perfoliatum was introduced from North America, and was figured in the *Botanical Magazine*, t. 3354. *S. A.*

SOME LYCHNIS SPECIES.

The most valuable species of the genus Lychnis are natives of Europe and Asia, a few less important hailing from America. All succeed in ordinary garden soil, whether perennial or annual, and are increased by seeds or division of the root-stock. These two operations may be carried out in early autumn or in spring. A few of those better known to me include:—Lychnis Lagascae, a charming, compact subject for a warm ledge of the rock garden or a dry wall. The bright rose-coloured flowers are freely borne when a plant becomes nicely established. It may be raised from seeds and is not more than three inches to four inches high.

Lychnis chalcedonica is a well-known occupant of our hardy flower borders, growing usually three feet or more tall. There are single and double forms in both scarlet and white; there are also some intermediate shades, but these are not of great value. With this species increase is also by division and seeds, while any special shade or form is best kept true by means of cuttings.

Lychnis Haageana is an excellent plant for the front of the flower border, its height being about one foot. The flowers are nearly two inches across and include scarlet, orange, white and other shades. Of hybrid origin, it is easily raised from seeds, while the stronger roots may be divided. On well-drained land the plant is a good perennial, but on wet land it has a tendency to die off. Lychnis Haageana var. Arkwrightii was raised by Mr. John Arkwright, of Kinsham Court, Radnorshire. The flowers of this are very large and superior. It is a hybrid between L. chalcedonica and L. Haageana.

Lychnis Viscaria, and also its double form, I used to grow as a rock plant. The foliage is dark green, while the foot-high flower stalk is capped with rose-coloured flowers. The habit of this plant is tufted, and there are several varieties.

Those of us who have engaged in rambles for wild flowers will remember L. Flos-cuculi as Ragged Robin. The flowers have deeply-cut petals, are rosy-coloured, and the plant is about two feet high. It is a native plant of Britain and is well adapted for moist places in the semi-shade of the woodland garden. L. Coronaria is better known to some as Rose Campion, being remembered by its woolly leaves. It is perennial, but often succumbs on wet land when one least expects this to happen—the whole plant rotting off at the ground-level. Happily, this Campion seeds freely and will re-sow itself if a plant is left for the purpose, a light and dry soil favouring the safety of the seedlings.

L. fulgens, as the name indicates, has flowers of very bright colour, while the petals are four-cleft and much resemble those of Ragged Robin in appearance. Being but a foot or so high, L. fulgens is eminently fitted for grouping at the front of any herbaceous border. L. alpina, like Lychnis Lagascae, is best grown in a warm corner of the rock garden. The colour of the flowers of these two kinds is very similar—rose-coloured. It is also of tufted habit, throwing up four-inch flower stems.

As all the foregoing Campions are easy of management they should commend themselves to planters of herbaceous borders and rock gardens during the coming spring. For all of these the soil should be on the light side, and if moderately enriched will give superior results. Excepting the rock garden species, the Campions here noted will do well in semi-shaded places, but preference should be given to sunny sites if the soil is cold and heavy. *C. Turner.*

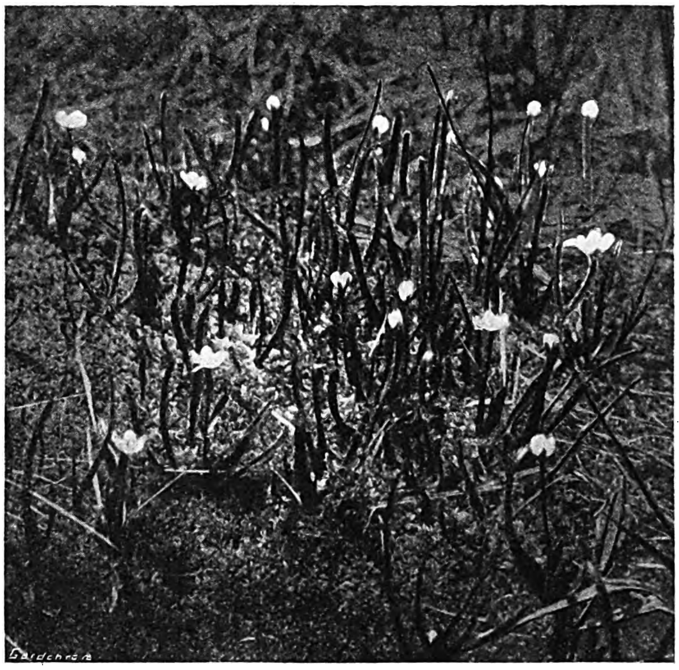

FIG. 5.—DROSERA ARCTURI.

TWO NEW ZEALAND DROSERAS.

Droseraceae is a small group of Saxifrageous herbs kept in a separate order because of their peculiar and similar habit. The whole of the species capture insects, usually by viscid and irritable, glandular hairs. The Sundews are chiefly inhabitants of peat and Sphagnum bogs, and are found in most parts of the world. Six species are found in New Zealand, only one of which is endemic.

In many high mountain areas water is constantly welling out of the soil in varying abundance, keeping the soil icy cold and tending to cause the formation of a continuous covering of Sphagnum-moss, which is saturated with water, except after a period of drought, when the surface will be dry. Droseras are frequent colonists in such areas.

D. Arcturi, Hook. (Fig. 5), is one of the commonest species found in New Zealand, where it grows in Sphagnum bogs anywhere between 2,000 feet and 5,000 feet. It is a small, erect herb with ligulate radicallea, ves from two inches to four inches long. The upper portion is covered with glandular hairs, the lower half is glabrous, while the petiole is almost as broad as the blade. The slender flower stalk, which may reach a height of six inches, rarely bears more than one white flower. The flowers open only during bright sunshine, when they are about one-third-of-an-inch in diameter.

D. binata (Lab.) is the most conspicuous New Zealand species. It is a fairly common plant on wet heaths from sea-level to 2,500 feet. The short root-stock bears many fleshy rootlets. The leaves are all radical, from four inches to eight inches in length, the upper portion being divided—and sometimes sub-divided—into two equal linear lobes which are clothed, on the upper surface and the margins, with glandular hairs. The flower-stem, which bears a loose panicle of fairly large, white flowers, grows to a minimum height of eighteen inches.

The other New Zealand species are quite inconspicuous and are scarcely worth growing, except in a botanical collection.

If cultivated under glass the Sundews require to be grown in peat and living Sphagnum-moss. The pots must be kept in saucers full of water in a cool greenhouse, but most of the New Zealand species should succeed in the bog garden in the milder parts of Britain. In such a garden these delicate herbaceous plants may be made quite a striking feature; their thick clothing of glandular hairs have the appearance of being drenched with dew drops and are a charming sight when seen sparkling in the sunlight. *A. W. Anderson, Botanic Garden, Dunedin.*

FLOWER GARDEN.

LAVATERA OLBIA.

Many references have been made in *The Gardeners' Chronicle* to Lavatera Olbia, a species which was once regarded as a difficult subject to manage. In later years, however, it has gained steadily in popularity, and at certain exhibitions large groups of it are seen occasionally. Now it has become a useful plant for summer displays, and large groups of its elegant stems and dainty flowers are seen occasionally in such magnificent displays as those in the long border at Hampton Court, while in Regent's Park it has been pressed into service as a summer bedding plant (Fig. 1) with Nemesias as a groundwork. This combination was a very charming one, distinct and suggestive to those who have to provide new and interesting floral effects in the garden during the summer season.

Lavatera Olbia reaches a height of five feet when in flower and well grown. This native of southern Europe is also a useful pot plant for conservatory decoration, where its clear, shining, rose-pink flowers are always admired. *C.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

THE BUSH, ANTRIM.

GOING up to the house, compressed between bushes of hybrid Rhododendrons bulging with bloom, the visitor catches a glimpse of the glory of Mr. H. D. M. Barton's garden on his right; for through the screen of fine specimen trees, including Lawson's Cypress, Douglas Fir, Abies grandis, Picea pungens glauca, Cupressus macrocarpa, and other American Conifers, the eye is caught by the tossed flowers of Oriental Poppies, rocking like pillar boxes adrift on a sage-green sea, which breaks into a lather where waves of the neat Helichrysum bellidioides (a settler from New Zealand) drape over a ledge. This is the first sight of the famous rock garden. However, let us work up gradually to this climax of the gardener's skill.

At the white iron gate which opens off the sunk road, little used by traffic even in these days, are the clumps of brightly-coloured Rhododendrons referred to above, set off by an occasional frowning Irish Yew, and a voluminous specimen of Cryptomeria japonica elegans, all bronze-tipped as though caught and held in a noose of sunset.

The pebbled drive, ascending, sweeps round the lawn, which, like the rock garden on the other side, is screened by trees and shrubs. Particularly attractive in summer are Rosa Moyesii, R. Hugonis and the sweetly-scented R. carolina var. Nuttalliana; and in autumn, a group of small Acers, of the palmatum type, which flame into orange and scarlet. There is a fine clump of Arundinaria anceps, with culms fifteen feet high, arching gracefully over; the gold-tipped Athrotaxis laxifolia; Cornus Kousa, whose white flowers blush with confusion as they die; a big tree of Prunus cerasifera var. Pissardii; Stranvaesia undulata; Eucryphia pinnatifolia; Kalmia angustifolia; and scattered Azaleas, Funkias, Paeonies and occasional Magnolias, and hybrid Rhododendrons.

Then the drive takes a twist, and we emerge suddenly into the open again, and from the front of the house look over the lawn, across the sunk road in one sweep to the tree-girt countryside, with the blue Loch Neagh lying serene in its emerald bowl, and the bluer mountains of Tyrone beyond that; and at the edge of the lawn is a magnificent purple Beech forming a billowy pyramid, the lowest branches of which sweep the ground.

Turning to the grey stone house itself, the wall is dabbled with the little, pouting, ruby mouths of Tropaeolum speciosum (which grows like a weed so long as its roots do not get dried), and in the corner, a silver bush of Anthyllis Barba-Jovis. The south front of the house faces the walled garden, where beds of Roses and Violas and Begonias in a small lawn suggest a return to the severest formality. But the impression is fleeting, for the walled garden, whose paths are spanned by arches of Golden Hop and rambler Roses, is alight with Oriental Poppies, Sweet Peas, Larkspurs, Snapdragons, Monkshoods, Paeonies and Foxgloves, with the tall, crowded spires of Lupins, and the seething orange of Mulleins sticking up here and there out of the mixture.

On the south wall of the house are many interesting shrubs, such as the carmine Sutherlandia frutescens (it recalls Clianthus puniceus), a rare plant in Britain, almost unheard of in the open; a fine specimen of the quaint Abutilon megapotamicum; Eccremocarpus scaber, from Peru, covered with little, hanging, red urns, and reaching to the roof; the Potato-flowered Solanum crispum; a fine bush of Ceanothus thyrsiflorus; Wistaria, and large-flowered hybrid Clematises, including the dainty, virginal-white Bride. Mr. Barton has made several efforts to cross the red and yellow Abutilon megapotamicum with the white form of A. vitifolium, which grows here in the open; but, so far, the plants raised have not revealed any megapotamicum blood.

A small bush of Fabiana imbricata grows sturdily against the wall, and a clump of Dutch Irises, tinted in delicate water-colours, completes a June picture. There is much more in the walled garden of course—beds of seedling Primulas and household vegetables and fruit trees, for instance, and many more flowers; but it is time to pass out through the wooden door in the corner, and go down the path towards the rock garden, by the wall where the herbaceous border is, along the pleached alley. Here the scented, yellow Martagon, Lilium pyrenaicum grows in sheaves, with the royal-purple Orchis foliosa, blue Delphiniums, man high, Polemonium coeruleum, and a rampagious growth of Geranium armenum; the grey wall itself is mottled with clumps of lurid Aubrietia, Campanula and an occasional spouting fountain of Saxifraga longifolia. The pleached alley is roofed with Golden Hop, rambler Roses, Clematises, Honeysuckles and Berberis Darwinii, and is flanked on the other side by bushy trees of Abutilon vitifolium, with delicious lilac flowers, and the neglected but charming Viburnum Opulus.

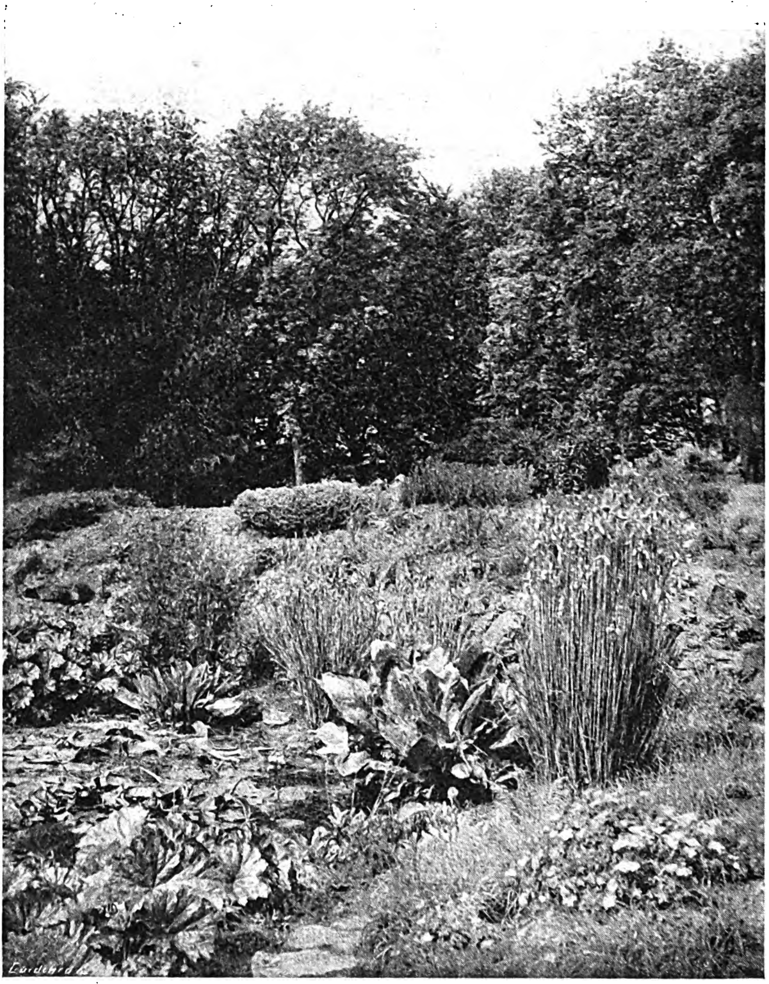

FIG. 6.—THE BUSH, ANTRIM: ROCK GARDEN AND POOL.

But enough of lesser things. The visitor has now reached the upper end of the rock garden, and henceforth will have no eyes for anything else. A bird's eye view shows an undulating rocky country, drained by a central valley, through which a stream winds its way from an upland marsh, to a small lake shut in the hills. Just beyond the lake, however, the spurs flatten out to the plains, and the stream, checked in its stride, forms a bog, backed by woods. The whole is brimful of flowers, their colours waxing and changing as the sun rises over the marshland, hangs for a space over the mountain tops, and drops swiftly behind the woods on the edge of the plain. Such, in miniature, is the rock garden.

If we stand on one of the high ridges which rise above the lake, we shall be able to look down on to the fluffy purple and white clouds of Thalictrum aquilegifolium, and the creamy mists of Polygonum alpinum, and see in the distance the plain all starred and sheeted with Primulas of many colours; or looking in the other direction, across hill and dale, see the fierce, fiery globe of some Oriental Poppy, rising like a warning sun over the jagged ridge, behind the blue seas of Anchusa myosotidiflora.

Tucked away among the cliffs and rocks are little jewelled alpine valleys and sun-baked escarpments, where clumps of the Chilean Torch Lily, Hippeastrum pratense (also known as Habranthus pratensis) glow red-hot among cool, white and yellow Iceland Poppies. This gorgeous plant is not nearly so common as it might be, although it thrives here in a climate which is cold, wet and windy. With it are clumps of the saffron-yellow, Iris-like Moraea spathacea, its long, grassy foliage sweeping the rocks. Among the rocks also, warmed by the stores of heat they lock up when the sun shines, are the New Zealand Celmisia Monroi, Geranium argenteum in silver and pink, Tulipa persica, Ramondia pyrenaica, tufts of the rare Parsley Fern and of the handsome Royal Fern, Primula Winteri, Trollius patulus, covered with large, bright golden saucers, and Anemone obtusiloba patula, an octopus-like plant whose questing arms end abruptly in blue flowers.

Narrow paths lead over hill and dale, threading their way among the vegetation, under cliffs, down valleys, or by the stream side; but so cunningly are they devised that they become lost among the flowers only a few steps ahead, and have to be sought with care. In places, one would never suspect a path at all, but seeing outspread carpets of Veronica filiformis, or Mimulus radicans, or Linaria aequitriloba, would be tempted to recline, and revel in the beauty of the scene.

And just as the paths melt into the mountains, so also do the shrubs vanish in the ocean of colour. Indeed, so perfectly proportioned is the garden, that at first sight shrubs appear to be entirely lacking, which is as it should be. Nevertheless, shrubs in some variety are shrunk into their appropriate niches, subordinated to the bold bluffs which overshadow them, the only exception being a magnificent specimen of Rosa Moyesii. Rhododendrons are scarcely grown here, only R. racemosum and R. ferrugineum being seen; but numerous Daisy bushes, such as Olearia Haastii and O. myrsinoides, throw up fountains of flowers, and hovering on the outer fringes of the highlands, in a far corner, are Magnolia stellata and Rubus deliciosus. Flowerful Brooms add a wealth of gold and silver. Genista tinctoria, clumps of Heather, Corokia Cotoneaster and Potentilla fruticosa crouch in their lairs, while vast, devouring cushions of Cytisus procumbens burst all bounds and tumble over the ledges, and C. purpureus spurts from between two rocks.

Herbaceous plants grow to a great size, notable being Euphorbia palustris and the red-leafed E. sikkimensis, Polygonum palmatum, and Gunnera. In the background are clumps of Bamboos, such as Arundinaria nitida and A. japonica.

The central lake (Fig. 6) is filled with water plants and around its rocky shore Iris sibirica sends up a fascis of thin wands, among which hover the blue, lace-winged, butterfly flowers. In the water grows the Skunk Cabbage, Lysichitum camtschatcense, and the spatheless Aroid, Orontium aquaticum, and the big leaves of Saxifraga peltata are reflected in it.

Groups of Irises of the sibirica type, of various degrees of affinity, prohibited and otherwise, crop up here and there amid jewelled crusts of pink, white and crimson Dianthus, whose parentage can be traced back to matrimony, holy and unholy, between D. neglectus, D. deltoides, and D. Griesbachii; or rather, cannot be traced back, so ravelled are the beautiful offspring. There are Gentians—G. tibetica, G. Freyniana and others, Campanulas, Saxifrages in assorted sizes, and the blue gem, Hyacinthus amethystinus; not far from the last, the shining gold and sea-green of Ranunculus graminifolius grows by the path-side, where golden torrents of Tropaeolum polyphyllum pour down from the crest of the ridge.

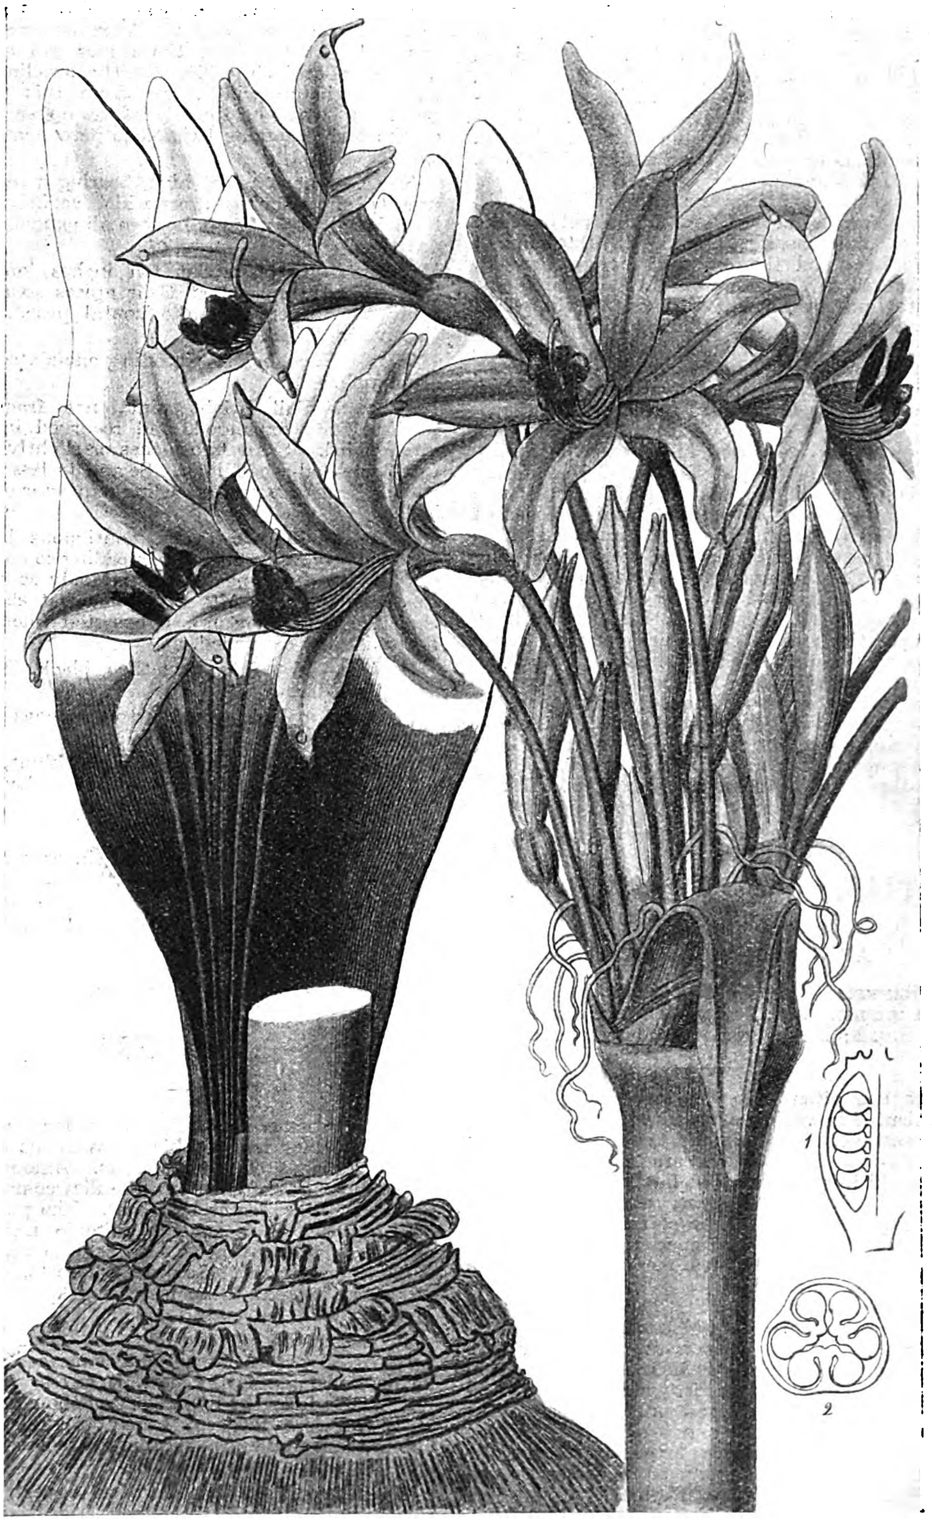

FIG. 7.—AMARYLLIS BANKSIANA.

1, Vertical section of one cell of the ovary; 2, transverse section of whole ovary. (see p. 12.)

(Reproduced from *Edwards's Botanical Register*, t. 11, 1842.)

Along the sides of the stream grow leopard-spotted Mimulus, and the twisted threads of amber, crimson and golden Primulas are drawn right through the warp of the hills. But mention of Primulas, which are the specia glory and pride of The Bush, recalls us to the upland marshes at the top end, where we shall see them in bulk. Here they are drawn up in regiments, as for a tourney, the sharp yellow platoons of P. helodoxa manning the trenches, the purple splendour of P. Beesiana and P. pulverulenta down in the marsh; the violet and white mops of P. cashmeriana, and the gorgeous flames of the new Bush hybrids, Lady Moore, Sir Frederick Moore and Lady Clanwilliam. The echo of glorious conflict here is indescribable; the colours clash and chime in the wildest harmony, and then into the fray sweep the fresh divisions from Tibet, and stalwarts from China, P. microdonta alpicola in all its colour range, P. sikkimensis, P. secundiflora, the gloomy P. prionotes, P. Wardii (Barton's variety), P. firmipes, P. reticulata, P. serratifolia, the snow-white P. chionantha, the bicoloured P. serratifolia, now rarely seen, and the gorgeous, ruby-flowered P. Waltoni. These are but a few of them, growing, not singly, but in drifts, with 'Sibirica' Irises, and nodding clusters of the dainty violet Aquilegia alpina, a neglected plant worthy of more notice, and the red Chilean Thistle.

Throughout the hill country we follow the trail of the Primulas, over a hundred kinds being grown here, although we can only mention a few of those which occur most lavishly. And as we approach the foot of the hills at the lower end of the garden, both along the stream bank and on the sagging slopes we find more Primulas, and varieties of Primulas, and hybrids of Primulas. A clump of the giant P. Florindae of Tibet has invaded the bog, and threatens to suck it dry. The scorching orange of P. Cockburniana, ignited by the molten spikes of P. Littoniana, explodes, and sets the vivid P. Poissonii smouldering balefully in the background! P. lichiangensis also grows here, and the ramping P. denticulata, long since over, and P. Bulleyana, and P. Smithiana.

There are also numerous species of Meconopsis, little clumps of blue M. Prattii, and fields of the yellow lampshade Poppy, M. integrifolia; while here and there a tall, moon-yellow M. paniculata or blue-flowered M. Wallichii shoots up to burst rocket-like and emit a shower of coloured stars. Besides the new Primulas raised at The Bush, there is the striking Mimulus bartoniensis, and several good hybrid Brooms have originated here. But one cannot name more than a selection of the fine plants which, during twenty years of selection and endeavour, have become established in the rock garden.

Finally, gardening at The Bush is a family affair. After dinner, like Aquarius, you seize the watering-pot—when the pressing needs of honey-bees swarming in some otherwise harmless Apple tree do not claim prior notice—and offer libations to Primulas. The very dogs—and they are legion—are allowed, nay, rather encouraged, to assist in a friendly spirit of co-operation; and if occasionally they do uproot a favourite Torch Lily in mistake for a weed, or tunnel beneath the very best Meconopsis in pursuit of a mythical mouse, well, poor little chaps, they enjoy it just the same. They love to scramble over the rocks and to fish in the pool, and puppy dogs and Primulas are all happy together in this garden of Eden. *F. K. W.*

PLANTS NEW OR NOTEWORTHY.

AMARYLLIS (?) BANKSIANA.

A. Banksiana of *Bot. Reg.*, 1842, Pl. XI; A. grandiflora var. Banksiana of Herbert, Pl. 32, Fig. 2; Brunsvigia Slateriana of Baker.

It has often fallen to my lot to unearth ancient Amaryllids of beauty and of historic interest which are unknown to most present-day gardeners. This time I am able to describe one which is on record as having flowered only once in English gardens, at Newick Park, Uckfield, about 1840, and so must be unknown to every English gardener now living. An opportunity has enabled me to examine the living flowers and leaf.

Amaryllis Banksiana (Fig. 7), belongs to a small group of Cape Colony bulbs which are so little known that one cannot even be dogmatic as to genus, especially as their fruits are not on record. Those authorities who have classed the plant here described under Amaryllis or under Brunsvigia have not exhausted all the possibilities of generic nomenclature, for the ovules and the synchrony of inflorescence and foliage is characteristic of Nerine.

The fine coloured figure in *Bot. Reg.* was taken on the first expansion of the earliest flowers, and so does not give the recurved poise that the flowers assume a few days later. Nor does it give the peculiar spiral twist that the upper part of the leaves assume when growth is mature. Herbert's figure is from a dried specimen, and the leaf does not belong to this particular bulb, as he himself warns us may be the case.

This is a bulb of beauty and individuality which will certainly appeal to many amateur growers, especially as it should be fairly hardy.

Description.

Bulb.—Deciduous, ovoid, about three inches in diameter, situated below the surface of the ground.

Leaves.—Appearing with the flower-scape in late autumn. Probably about six, erect, one-and-a-half to one-and-three-quarters-of-an-inch maximum width by one foot long, glabrous on the face, with many well-marked, parallel longitudinal veins, with a semi-transparent white, narrow, entire edge. Apex narrow and rounded. At the base the leaves are three-quarters-of-an-inch wide, shortly swelling to their maximum width, and from this point becoming flexed on the edges, the upper third of the leaf becoming twisted in two complete spirals.

Scape.—About a foot high, bearing a regular umbel of about thirty flowers, which last in beauty for a fortnight, and may be seen all expanded at one time.

Pedicels.—Erect, about ten inches long or less, abruptly curved at their apices so as to bring the flowers to a horizontal pose. Distinctly six-ribbed.

Tube.—None, or not exceeding one-sixteenth-of-an-inch.

Flowers.—Full bright pink, not fragrant, regular, fully expanded, and recurved in the upper third. Span two inches or slightly less. Limb one-and-a-half inch. Segments less than half-an-inch wide but exceeding a quarter-of-an-inch.

Stamens.—In two ranks, contiguous below but abruptly ascending and spreading somewhat above. At their apices they suddenly contract to a fine thread. Although somewhat shorter than the limb, they appear exserted when the flower is fully expanded.

Anthers.—Not fully versatile; black. Pollen grey to ochreous-white.

Style.—Equal in length to stamens and aligned with them.

Stigma.—Appearing as a simple, blunt, but not capitate, end of the style. The development of the stigma is delayed.

Ovaries.—Oval, green.

Ovules.—Two to four in a bunch, or grouped about the middle region of the placenta. Nearly sessile.

Fruit and Seeds.—Unknown. *A. Worsley, Isleworth.*

BULB FLIES.

Cultivators of Narcissi, whether for pleasure or profit, suffer considerable losses as the result of depredations of various pests. Among the more important of these are the flies commonly known as Narcissus or bulb flies. The purpose of this article is to suggest suitable methods of control, with a view to reducing the amount of damage attributable to these insects, which at present appear to be increasing appreciably in Great Britain.

It cannot be pointed out too often that, before really satisfactory control measures can be devised against any pest, it is essential to understand fully the life-history of the creature. It is therefore proposed briefly to sketch the habits of the flies before turning to the consideration of possible controls.

The large bulb fly, Merodon equestris, is closely related to the common and beneficial hover flies. It is about the size of a small humble bee and of similar appearance, being covered with long hair, which is usually arranged in brightly-coloured bands. These bands may be red, black, yellow or white, but sometimes the fly is brown or black all over. No particular significance attaches to the variation in colour, at least from the economic point of view. The fly may at once be distinguished from the humble bees by the fact that it possesses, as do all flies, but one pair of wings. The adult flies appear first towards the end of April. During May and early June they lay eggs, singly, on or near Narcissus bulbs, and may often be seen congregated in warm corners of the bulb garden, or flying rapidly too and fro over the bulb beds.

The actual site selected for the egg is of importance. At the time that the eggs are laid, the foliage of many varieties of Narcissi is dying down. The soil is frequently dry and, as a result of the shrivelling of the foliage, a crack in the soil is often left, extending sometimes actually down to the bulb itself. The egg is placed on the foliage, on the earth surrounding the bulb or sometimes on the bulb itself. In a few days the egg hatches and the small larva immediately travels down the aperture in the soil and bores into the bulb. Having reached the centre, it bores through in a longitudinal direction, usually destroying the growing point and sometimes the whole bulb. In other cases, numbers of adventitious buds develop around the destroyed growing point, and eventually large numbers of small bulbs are formed, which in the next season throw up a circle of small foliage referred to as "grass" by commercial growers.

The larva is a large sluggish creature, resembling a leather-jacket in appearance. It remains in the bulb during the whole summer and subsequent winter, leaving it in April and pupating in the soil nearby. The adult emerges, as previously mentioned, late in April or early in May. It is thus seen that only one generation of the fly occurs each year.

The lesser bulb flies, Eumerus tuberculatus and E. strigatus, are of very similar appearance and identical in habits, and may for our present purpose be considered as one.

The adult flies are slightly larger than house flies, but they are much flatter and broader. They are of a bronze, metallic colour, like some of the smaller wild bees, from which they may be distinguished, as in the previous insect, by the possession of only one pair of wings. In addition, they may be identified by six pale white or greyish coloured, crescent-shaped marks on the upper side of the abdomen.

These flies appear at the same time in the spring as do the large ones, and may be seen darting rapidly over the bulb-beds, a few inches from the ground, or settling on the foliage. Eggs are laid in the same positions as are those of the former fly, with the difference that, instead of being laid singly, they are laid in batches of from three to fifty at a time. Usually the batches each consist of from five to twelve eggs.

Small maggots emerge from the eggs, after a few days, and these immediately crawl down to the bulbs, but instead of making for the basal area they usually congregate at the point where the dying foliage joins the neck of the bulb. Here they commence to feed, at first on the rotting tissue, and then, as they grow stronger commencing to break down the living bulb, which, if they are at all numerous, they quickly reduce to a hollow shell of rotting matter.

These first-generation larvae feed up rapidly and at the end of about four weeks leave the bulb and pupate in the dry outer scales, or in the earth, and two or three weeks later emerge as a second generation of flies. These flies again lay eggs, and the resulting maggots enter bulbs as before. The majority of them feed more slowly than those of the previous generation and remain in the bulbs until the following March, when they leave the bulbs, pupate and emerge again as adult flies. A few larvae do, however, feed up quickly and produce a partial third generation of flies in September and October of the same year. These latter flies have never been seen to lay eggs.

It may be stated that the rather generally held opinion that the lesser bulb flies lay eggs only on bulbs already diseased, is incorrect. It has been abundantly proved that the flies oviposit on, and the resulting maggots attack and destroy, bulbs which were previously sound. Furthermore, both the large and the lesser flies oviposit freely on bulbs exposed on the surface of the ground, and it will be shown that this has an important bearing on the control measures which can be adopted against these pests.

REMEDIAL TREATMENT OF BULBS.

All bulbs which feel soft and spongy should be rejected at the time of planting, as they very likely contain fly larvae. Rejected bulbs should be destroyed by burning or burying in a deep hole. If they are merely left lying about the grubs in them will be able to mature, and in due course produce flies, which will return and attack other bulbs. If not destroyed, they should be subjected to one of the following treatments:—

Hot-water treatment.—The immersion of dormant bulbs in water, at a temperature of 110°F., for a period of three hours, is universally adopted as a method of destroying bulb eelworm (Tylenchus dipsaci). This method of treatment is widely-known, and need not be described here. Sufficient to say that it will destroy also all bulb fly larvae and other pests in the bulbs.

Fumigation of bulbs with paradichlorbenzene will destroy the larvae, if correctly carried out. It is an excellent method of dealing with a small quantity of bulbs, when a hot-water apparatus is not available. The bulbs must be placed in an air-tight container and sprinkled with crystals of the substance, using four ounces to every cubic foot of space. The bulbs must be left in the container for five days and then removed and aired well. An old biscuit-tin makes an excellent receptacle in which to treat a few pounds of bulbs.

PREVENTIVE TREATMENT.

It is a common practise to ripen lifted bulbs by leaving them exposed on the ground for some time after digging. The practise is not altogether good in itself, for serious damage frequently results after such treatment, as a result of sun scorch. Further, at the time that many Narcissi should be lifted, bulb flies are still ovipositing, and the bulbs thus fall an easy prey. The flies will not lay eggs under the most primitive of shelters. Bulbs should therefore be spread to ripen in an open shed, or if large numbers have to be handled, under a rough shelter which may very conveniently be constructed from a few posts and sheets of corrugated iron.

Small heaps of damaged and otherwise worthless bulbs may conveniently be left as decoy heaps in places where the flies are abundant. Large numbers of eggs will be laid on the bulbs, which may subsequently be removed and destroyed. Care should be taken not to leave the heaps out for too long, as it must be remembered that the flies mature in six weeks in the summer, and some may emerge from the heaps if they are left for that length of time.

It has been shown that the fly larvae cannot locate bulbs in the soil if the necks of the bulbs are well-buried. Normally, at the time of maximum oviposition, namely, May and June, the bulbs are more or less exposed, owing to the dryness of the foliage and the cracking of the soil. The simple process of raking over, harrowing or cultivating the bulb-beds, in almost any way, will have the effect of filling in the holes and cracks around the bulbs, and thus rendering them far less liable to be attacked. This procedure should always be adopted with those varieties which have practically lost their foliage at that time. With varieties in which the foliage is only yellowing, the same result may be obtained by cutting the foliage over and afterwards roughly earthing up the cut ends of the leaves and flower stalks. This procedure will not hurt the bulbs. Varieties which carry vigorous foliage late into the summer are best left alone. Observation has shown that the flies are not likely to attack them very seriously, for in the case of the lesser flies, at least, there is no suitable starting off point for the larvae to commence their attack.

In conclusion, it may be stressed that, while there is no golden rule for destroying all bulb flies, a combination of methods will greatly reduce the damage attributable to them. The simple cultural methods of raking over the beds earlier than is the usual practise, and drying and ripening the bulbs under cover, however primitive such cover may be, will, to a considerable degree, bring about the desired reduction in the number of bulbs lost as a result of attack by bulb fly larvae. *W. E. H. Hodson, A.R.C.S., Newton Abbot.*

THE CULTIVATION AND USES OF HENNA.

HENNA (Lawsonia alba, Lam.) has been cultivated in the east for centuries, with the result that it is very difficult to determine where the plant is really indigenous. Probably, however, it is a native of Arabia, Persia and countries on the north African coast. The shrub is a member of the Natural Order Lythraceae, and is the sole representative of the genus Lawsonia. It is true that two species were distinguished by Linnaeus, L. spinosa, with spines, and L. inermis, without; but these are now usually regarded merely as forms of L. alba, the difference being thought to be the result of age.

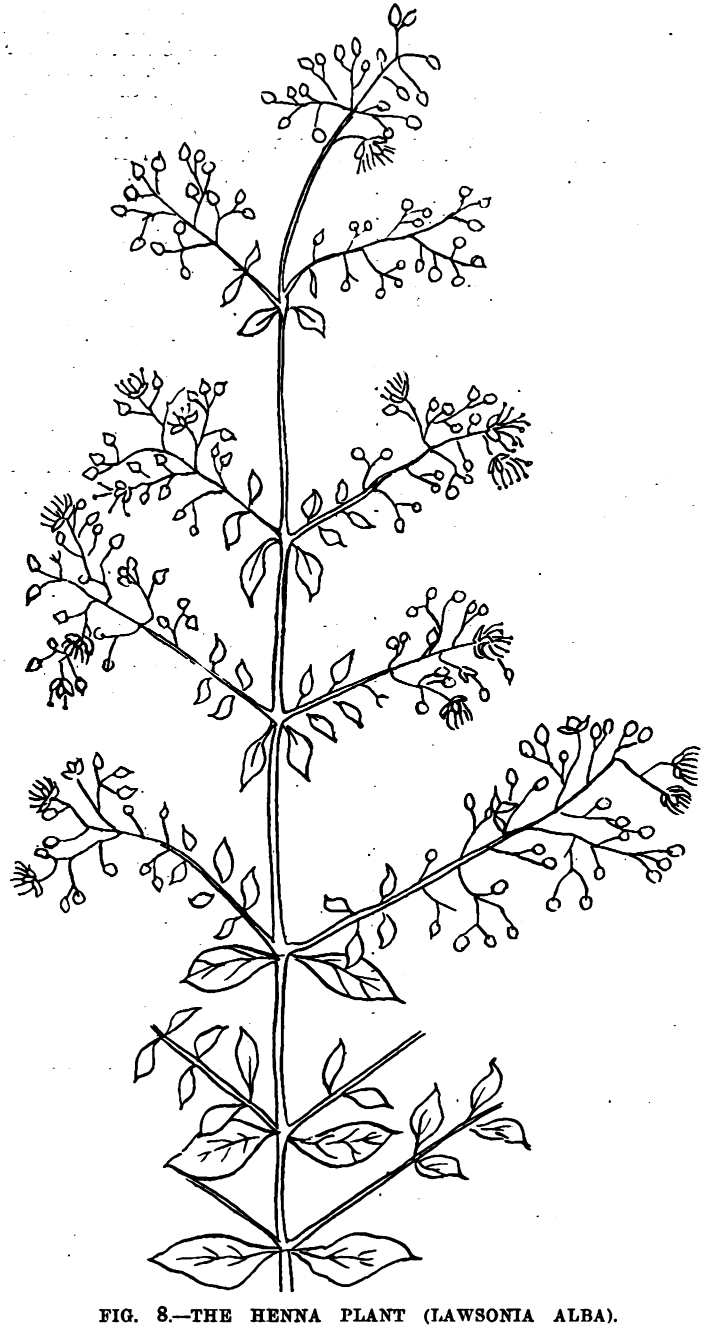

FIG. 8.—THE HENNA PLANT (LAWSONIA ALBA).

In the east, Henna finds many uses. The powdered leaves are employed by the ladies as a cosmetic, for dyeing their finger-nails, the palms of their hands and the soles of their feet red, this being a custom universal among Mohammedan women and one practised to some extent by Hindus also. The powder is also used as a hair-dye, either alone to dye the hair red, or mixed with "reng"—powdered leaves of Indigofera argentea—to produce a fine blue-black. The fragrant flowers are employed by eastern women for purposes of personal adornment, and an oil is distilled from them which is used, in the east, as a perfume.

It is uncertain whether Henna possesses any therapeutic properties; but in India and elsewhere in the east it is credited with marvellous medicinal powers, and various preparations of it are employed for treating a number of diverse diseases. Poultices made from the roots or leaves appear to be effective in relieving sore feet; the same, unfortunately, cannot be said of a decoction of Henna as a cure for leprosy, although used for this purpose by natives in India. There is a tradition that Mahommed dyed his own beard with Henna and declared it to be the "best of all herbs," which may account for some of the more fanciful applications to which Henna has been put in Mohammedan countries, such as burning the seeds to drive away evil spirits.

The real use of Henna as a hair-dye, however, has made it a plant of considerable industrial importance, large quantities of leaves being imported each year into Europe for this purpose. Henna owes its peculiar efficacy as a hair-dye to the presence of a hydroxynaphthaquinone, first isolated from the leaves by Tommasi, and christened "lawsone," which acts as a substantive red dye towards the keratin of living human hair and skin. Henna is popular as a hair dye, because of its innocuous character. To produce a range of shades, other dyestuffs, not always equally inoffensive, are incorporated with it.

Lawsonia is a shrub, normally attaining a height of from six to nine feet, and bearing an abundance of leaves and small, very fragrant flowers of a whitish colour. The leaves are opposite, glabrous, undivided, and elliptical in shape, with pointed ends. They vary in size from about one to one-and-a-half inch long, by one-half- to three-quarters-of-an-inch broad. The colour of the flowers is variously described as greenish-white or creamy-yellow, climate and the method of cultivation probably having some effect on this, as it appears also to have on the number of stamens, which, normally eight, is stated usually to be only four in the case of shrubs growing in Egypt.

As mentioned already, Henna is widely cultivated in the east. There are many plantations in India, China, Persia, Egypt and especially Tripoli. This shrub has also been naturalised in Jamaica. In England it can only be grown under glass, in a hot-house; there are some living plants in the Kew collection, but they do not flower.

In India, Henna shrubs are used for hedges in some places, and are planted in gardens, finding favour because of the fragrance of the flowers. When, however, Henna is grown for commercial purposes, the shrubs are not allowed to flower, but are cut down, usually twice a year. This treatment facilitates the growth of an abundance of leaves, which constitute the economically valuable part of the plant. The shrubs may be grown from seeds or propagated by means of suckers or cuttings, and thrive best in a damp soil.

The harvest takes place in February to May, and again in August to November, being a month or two earlier in Tripoli than in India. The cut stems are stripped of their leaves, which are dried in the sun and finally powdered, the shrubs continuing to yield leaves over a period of twelve years or more. The amount cut each time varies in the different countries in which Henna is cultivated. In Tripoli, where the plants are cut practically to the ground, the annual yield of dried leaves per acre is about fifteen to nineteen hundredweights.

Lawsonia alba rejoices in an abundance of popular names, such as Indian Privet, Egyptian Privet, Jamaica Mignonette, Reseda de Cayenne, etc., which, if botanically misleading, bear testimony to the wide distribution of the plant.

My best thanks are due and are hereby tendered to the Director of the Royal Botanic Gardens, Kew, for valuable information concerning Henna, and to Miss V. A. Venables for kindly preparing the sketch of Henna in bloom (Fig. 8), illustrating this article. *H. Stanley Redgrove, B.Sc., A.I.C.*

PLANT HISTORY IN NOMENCLATURE.

(Continued from p. 470, Vol. LXXXIV).

TOBACCO AND ITS DERIVATIVES.

If the Poppy with its opiate is associated with war, Tobacco fills the pipe of peace, and therefore merits our next consideration. Only when we come to study the subject in detail does it dawn upon us how greatly Tobacco has affected our vocabulary. The "fragrant weed" as it is fondly called by the devotee, is the leaf of a plant known to science as Nicotiana. It was so named in honour of M. Nicot, a French Ambassador to Portugal, who first obtained seeds from a Dutch merchant about 1560, and sent the plant to Catherine de Medici. It thus came about that a large genus of plants belonging to the Nightshades (Order Solanaceae) was eventually included under the name, while the essential principle came to be known as Nicotine. The term Nicotian, meaning that which pertains to Tobacco, comes from the same source, and is the equivalent of the French *Nicotiane.* This is only one of many plant-names derived from those of distinguished men.

Turning to the word Tobacco, we find that it is, by some, stated to be derived from a place-name. Just as Damson comes from Damascus, and Currant from Corinth, so Tobacco is popularly said to be derived from Tobago in the West Indies, or Tobasco in Mexico. That, however, is very doubtful. In any case, it comes to us in the first place through the Spanish *Tobaco,* and is included by Brachet in his *Etymological French Dictionary* among the words of Spanish origin which came into French at the end of the sixteenth century. In his *History of Mexico,* Clavigero informs us that it was taken from the language spoken in Hayti. Tobacco is the Cuban name for the pipe, or tube for smoking, and elsewhere the word Tobaco is used for the pipe as well as for the weed. From Tabaco the French have derived such terms as *tabac, tabagie* and *tabatiere* or *tabaquière,* while in England we speak of the tobacconist, and have produced a number of compounds into which the word Tobacco enters.

In China and the East, Tobacco is not less popular than Opium, and the study of the word *In,* which originally means 'smoke' in Chinese, is very suggestive, since it shows that the Celestial Dictionary is as largely affected by plant-history as our own. A great deal might be written about the secondary effects of Tobacco smoking on languages, but it would take us too far afield to deal with such terms as buri, shisha, kiseru, tung, hookah, nargileh, kalyan, hubble-bubble and the other words employed in many tongues for the water-pipes which are in almost universal use in eastern lands.

Tobacco is largely grown in China, and some useful remarks on the subject may be found in Gray's *China* (Vol. II, 146, seq.). The author remarks on the use of the hookah in Canton. It is not, however, known under that name, but Gill, in his *River of Golden Sand,* tells us of an old man who had been to Lhassa, and informed him that the people in that city smoked hookahs, the body of which was made of brass while the long stem was of wood. The old informant added that fire was put in at the top, and described the water-pipe exactly, using the very word hookah. Every traveller is aware of the value of Tobacco in places which are little in touch with the outside world. To smoke with the natives is usually to secure their good will, and a pipe is the symbol of peace.

That Tobacco was originally smoked in pipes seems clear from the fact already mentioned that the word Tobaco means a pipe in some of the American languages. But the leaves are also used for making cigars and cigarettes, and thus we come to a totally new set of words. Cigarette is, of course, simply a diminutive of cigar, a word which, like Tobacco came to us through the Spaniards. It is sometimes spelled segar, but the Spanish form is cigarro, "originally a kind of Tobacco from Cuba." Its French form is cigare. Cigarro must not be confused with Cigarra the Spanish name for a grass-hopper or the Cicada, otherwise named a Cicala. In the east, cigars are greatly in request, and travellers have much to say about them, their names and qualities, and the estimate which is formed of the smoker by the brand which he affects. Smoking one kind he may pass as a prince; he sinks to a pauper if he uses another. In China, as among ourselves, they bear the names of the countries or places from which they are introduced. Hence, they speak of the Makoo or the Luisung as we do of the Manilla or Cuban.

If we would rightly estimate the influence of Tobacco on language, however, we must remember that it has not only been shredded, and so used in the pipe or for making into cigarettes, but that it has been used in other ways. While the sailor has his twist and the villager his quid, the swell has his cigar, and the student or politician has, or used to have, his pinch of snuff.

While the pipe has had much skill lavished upon it, the snuffbox has probably had a much greater influence on art, especially those branches which more immediately concern the goldsmith, silversmith, enameller, jeweller, japanner and miniature painter. This, however, is a branch of study which, while immediately concerned with the plant under review, does not affect the dictionary or bear upon nomenclature.

Our subject would not, however, be exhaustively treated if we did not notice how the word "smoke" in connection with tobacco has entered into the amenities of life, and extended, if it has not greatly enriched, our vocabulary. On the train we find our smoking compartments, in hotels the smoke-room or smoking saloon, and without the smoking concert many a charitable institution would soon decline for want of funds.

The spittoon is now very much a thing of the past, but it was once, like the "churchwarden" a smoker's requisite. The name Smoke-wood, or Smoking-cane, is frequently applied to the Traveller's Joy (Clematis) on account of its stems being used by boys in the place of a cigar.

While the Tobacco plant is known to be a native of America, its cultivation in many other lands has for some centuries been a remunerative industry. Some maintain that the produce of the plantations in southern Rhodesia bears the palm, while others maintain that Cuba or Manilla remain unrivalled. The Chinese obtained seeds at the same time as ourselves from the Spanish, Dutch or Portuguese traders, and have ever since been keen cultivators of the fragrant weed, although they still import the choicest kinds. Half-a-century ago, I saw magnificent Tobacco plantations at Kong-mun in the province of Kwang-tung. So early as the year 1641, the reigning Emperor issued an edict forbidding his Manchu subjects its use. Popes, kings and emperors have, however, issued their counterblasts in vain. The smoking habit grows, and until man has learned to live without the use of narcotics, opiates, stimulants, sedatives, anodynes and palliatives, we must, perhaps, admit that the least injurious of these is "the fragrant weed." *Hilderic Friend.*

(To be continued).

THE GENUS PRIMULA.

(Continued from p. 510, Vol. LXXXIV).

HYLOPHILA (Balf. f.). Thin-leaved P.
(Petiolaris-Davidi.)

A BEAUTIFUL perennial species with a rosette of membranous leaves about three-and-a-half inches long, with elliptic or oblong-elliptic blades about two-and-a-half inches long and one-and-a-half inch wide, rounded at the tip, more or less abruptly contracted at the base into a short stalk about one inch long; margins furnished with short, irregular teeth ending in horny points; both surfaces thickly dotted with glands and sparsely downy. Flower stem slender, glandular-downy, about two-and-a-half inches tall, bearing from two to eight lilac-rose blossoms on stalks about three-quarters-of-an-inch long, in a wide, loose umbel. Corolla flat, about three-quarters-of-an-inch across, divided into five broadly heart-shaped lobes, cleft into rather narrow, rounded segments; tube white, about half-an-inch long, cylindrical below, swollen upwards but constricted at the mouth, where there is a ten-lobed, white-rayed ring, tinged green beneath. Flowers in April and May. Not in cultivation.

Grows in cool, shady gorges, sometimes in loose limestone and also on rotten tree trunks, in the forest regions of northern Burma and southern Yunnan, at 7,000 feet to 9,000 feet above sea-level.

Culture: Friable, calcareous loam, Oak or Beech leaf-soil and sand, in a damp, cool, shady spot, with protection in winter, are the conditions indicated.

HYMENOPHYLLA (Balf. f.). Membranous-leaved P.
(Cortusoides.)

A moisture-loving perennial considered to be a sub-species of P. polyneura, with a tuft of long-stalked, erect leaves about six inches long, with thin, rounded or elliptic blades, heart-shaped at the base, about three inches across, very deeply divided into eleven blunt lobes, margined with two to three fairly sharp teeth; both surfaces more or less downy; stems stout, sparsely downy. Flower stem about twelve inches tall, sparsely downy, bearing an umbel of about half-a-dozen purple blossoms on erect, downy stalks about three-quarters-of-an-inch long. Corolla over three-quarters-of-an-inch across; tube cylindrical, downy outside, with a ring in the mouth. Flowers in July.

Grows in wet alpine pastures near Doker-La, Tsarong, south-eastern Tibet.

Culture: Grow it in friable loam and leaf-soil in a damp, cool spot with an easterly exposure.

HYPOLEUCA (Hand.-Mzt.). Pearl-leaved P.
(Malacoides.)

This plant is probably of biennial duration only, and appears to be a sub-species of P. Forbesii. It produces a many-leaved rosette of oblong-elliptic leaves three-quarters-of-an-inch long by half- to three-quarters-of-an-inch wide, rounded or nearly square at the base and tip, borne on narrowly-winged stalks about equalling the blade in length; margins furnished with small lobes or coarse teeth; upper surface more or less smooth, underside coated with greyish-white meal. Flower-stem seven to ten inches tall, erect, bearing two to three superposed umbels of four to ten blossoms placed some two inches apart up the stem, on stalks half-an-inch to one inch long. Corolla rose-coloured, about half-an-inch across, divided into five heart-shaped lobes; tube cylindrical, about a quarter-of-an-inch long. Flowers in June. Not in cultivation.

Grows among reeds and marsh plants, on the borders of Lake Kunyang-Hai, in Yunnan, western China, at about 6,000 feet above sea-level.

Culture: The conditions indicated are a compost of peat and leaf-soil, kept saturated when the plant is in active growth.

IMPERIALIS (Jungh.). Imperial P.
(Candelabra.)

A robust perennial species with a tuft of spathulate foliage, with elongate-egg-shaped, blunt blades, two to five inches across, tapering to winged stalks, in all from four to sixteen inches long; margins sparsely toothed; both surfaces more or less smooth, non-mealy, rugose. Flower-stem stout, one to two-and-a-half feet tall, mealy upwards, bearing several many-flowered umbels of golden-yellow, orange-tinged blossoms. Corolla flat, about three-quarters-of-an-inch to one inch across, divided into five broadly heart-shaped, notched lobes; tube about twice as long as the calyx, cylindrical, dilated upwards, with an obscure ring in the mouth. *Bot. Mag.*, t. 6732. Introduced in 1891.

Grows in damp, shady places on the mountains of Java, at from 8,000 to 11,500 feet above sea-level.

Var. gracilis (Pax) is dwarfer than the type and has flowers about half-an-inch across, with their calyces densely covered with yellow meal.

Culture: Grow it in good, somewhat heavy loam, in a damp, half-shady spot, with protection from severe frost.

INAYATII (Duthie). Inayat's P.
(Nivales.)

A strong-growing species with flowers too small to be of any great decorative value. It produces a loose tuft of thin, flaccid, lance-shaped leaves, broadened at the tip, where they are either rounded or slightly pointed, and tapering at the base into a narrowly-winged stalk, in all nearly twelve inches long; margins furnished with recurved teeth; upper surface dark green, smooth, underside covered with silvery meal. Flower stem nine to fifteen inches tall, stout, downy upwards, bearing a loose, rounded umbel of six to twelve pale lilac blossoms, each with a yellow eye. Corolla about three-eighths-of-an-inch across, divided into five broadly heart-shaped, shallowly bifid lobes; tube short, cylindrical. Flowers in February and March. *Gard. Chron.*, 1923, Vol. LXXIII, Fig. 59, p. 121.

Grows on wet rocks in the Siran and Kagan Valleys, in the north-western Himalayas, at 4,500 feet above sea-level.

Culture: Good, somewhat heavy loam, in a damp spot, in sun or half-shade, should suit it; it is hardy and easily grown.

INCANA (M. E. Jones). American Hoary P.
(Farinosae.)

This dwarf, deciduous perennial is a sub-species of P. farinosa. It has a short root-stock with fleshy, fibrous roots and a rosette of oblong, oval, elliptic-oblong or oblong-lance-shaped, blunt leaves one to three inches long, gradually tapering to short, winged stalks; margins sinuately toothed above the middle, or nearly entire; upper surface green, at times slightly mealy, underside coated with white meal. Flower stem rather stout, four to eight inches tall, coated with white meal and bearing a dense umbel or head of eight or more lilac or purple, yellow-throated blossoms, sessile, or on stalks up to half-an-inch long. Corolla flat or slightly concave, about three-eighths-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindric, about three-eighths-of-an-inch long, slightly longer than the calyx.

Grows in swamps, wet meadows and bogs, in the Rocky Mountain regions of Montana, Wyoming, Alberta and Colorado.

Culture: As for P. farinosa, but is an easier plant to cultivate.

INCISA (Franch.). Incised-leaved P.
(Souliei).

A beautiful species with a tuft of scabrid leaves with oval, pointed blades half-an-inch to 1-inch long, tapering to a slender stalk from two to three times longer than the blade; margins furnished with sharply-cut teeth, or at times almost entire or lobulate; both surfaces clothed with short, stiff, rough hairs. Flower stem smooth, slender, two to six inches tall, bearing an umbel of two to six rose or violet blossoms on short, slender stalks. Calyx sparsely coated with golden-yellow meal. Corolla concave, about five-eighths-of-an inch across, divided into five broadly heart-shaped, very deeply bilobed segments; tube slender, cylindrical, dilated upwards, almost twice as long as the calyx. Flowers in April and May. Not in cultivation.

Grows in wooded regions near Moupine, in eastern Tibet.

Culture: Good loam and Beech or Oak leaf-soil, in a cool, shady, moist spot, with protection from wet in winter, are conditions most likely to suit it. *A. W. Darnell.*

(*To be continued*).

THE CAMOMILE OR SCENTED LAWN.

IN an interesting and suggestive article, Mr. Hay (see p. 491, Vol. LXXXIV), pleads that in reproducing the formal gardens of a past age, we might with advantage add to them the Camomile lawn, presumably for the turf surrounding or in the immediate vicinity of such old word gardens. Our thanks are due to him for the reminder, and if Camomile lawns are desirable, no doubt means will be found to produce them; we could also go farther, and add our own enterprise to the legacy of knowledge left us by the old writers. True, the Camomile has an aromatic scent, but that of many other dwarf plants is even more agreeable. If these could be induced to form a sward or were incorporated in the turf, it would be possible to have a scented lawn.

Those who have walked over the Sussex Downs know how springy is the turf, and how delicious the scent wafted back on the breeze from the footsteps of others in front. If we examine the sward we find the grass thickly interspersed with minute herbs, many naturally dwarf, others rendered so by their situation and the constant nibbling by sheep and rabbits. Among hundreds of interesting plants, those which contribute most scent are the Wild Thyme (Thymus Serpyllum), Corn Mint (Mentha arvensis), Marjoram (Origanum vulgare), Camomile (Anthemis nobilis) and Yarrow (Achillea millefolium), all reduced to a close mat of herbage very little taller than the grass on a lawn when shorn by a motor-mower.

It is a fact that many plants will make a close turf under the same treatment that we accord to our lawns. Few would suspect Gorse or Ling of doing so, yet both will combine with grass to form a thick sward. This is particularly noticeable where the lawn mower has been used over paths that pass through heaths or other comparatively wild country. The fact that they do not under such conditions produce seeds adds to their longevity. Some readers may be doubtful how long Camomile will exist in mown grass; probably it depends on how well the grass is fed. To my knowledge, Camomile has grown on Staplefield Cricket Ground, between the pitches, for upwards of thirty years During a bout of "stonewalling" and while waiting for another partner, its verdant character first attracted my appreciation: naturally, I regarded it, a new lawn plant, as my own discovery, but now the allusion is shattered. Verily; there is nothing new under the sun!

Probably I shall be told that scented lawns were well known to the ancients. Anyway, I can imagine a sunny terrace made wonderfully attractive by planting and mowing regularly a sward composed of a number of sweetly-scented, dwarf herbs. Besides those previously mentioned, all of which grow easily under cultivation, there is the Caraway-scented Thyme (Thymus Herba-barona), Lemon Thyme, a well-known variety of the wild Thyme, Pennyroyal (Mentha Pulegium) and Mentha Requienii; the Corsican Mint would be suitable for the moister and more shaded spots. There is no lack of scented plants, the only difficulty at first would be to choose the best.

It is astonishing how readily many small plants will establish themselves among grass that is not over-fed, and yet regularly mown. At Nymans we have the minute Veronica repens threading through the grass, and flowering thickly in springtime below the cut of the mower. I have also seen Selaginella Kraussiana fully established among grass in a shady corner.

It would be doubtful, until decided by experiment, if herbs alone should compose the turf or whether they should be planted at the same time the grass seeds are sown. It would be useless to plant in established turf. These, however, are details which could be easily determined by anyone with the time and patience to give the making of a scented lawn a trial. *J. Comber, Nymans Gardens.*

I WAS much interested in the above subject discussed so admirably by Mr. T. Hay. He states that "the full story of the lawn has yet to be written." While that is true to-day, it is quite possible that someone may repeat the statement in 2028. I have known a Camomile lawn since some time in the nineteenth century, and possibly Mr. T. Hay had the same lawn in view while he wrote. If so, it would be unwise to make it public, for good reasons. Furthermore, I have seen a Camomile tennis lawn, and whether or not the owners knew of the presence of Camomile, I cannot say; but there was no evidence of an attempt to eradicate it. The plant was perfectly native to the soil on the lawn and over an extensive area outside it. On the clay soils of Surrey, lying to the south of the North Downs, Camomile (Anthemis nobilis) is seldom absent from any village green, and gives off a very agreeable odour when walked upon. Looked at from this point of view, Camomile lawns, open to the public, are numerous, although few people record it.

If my memory serves me right, Evelyn lived in the region to which I refer, and in that case he could have obtained an idea of a Camomile lawn from the natural surroundings. The modern lawn at its best consists of grasses only, but the late Shirley Hibberd once advocated the Pearlwort (Sagina procumbens) for the making of lawns in some situations at least. Model lawns of this are occasionally seen at the meetings of the Royal Horticultural Society. In the early seventies of the last century, Chrysanthemum Tchihâtchewii was recommended as a subject for dry banks. It is a procumbent perennial, similar to Camomile, and might make a lawn on sandy soils. Has Thymus Serpyllum ever been tried for the making of a lawn on dry soils? *J. Fraser.*

NOTICE OF BOOK.

The Pear and its Culture.

In this book,* written for both the amateur and the commercial grower, the author has brought together the more important items in the culture of Pears, as carried out in America. That country, he states, has no native Pear. All the varieties found in the New World have come from the Old at one time or another. These in turn trace back to a common ancestry somewhere in Central Asia. From this original form there have finally evolved two general groups of species, oriental and occidental. Of the latter group, there are only two species of importance, so far as Pear culture is concerned to-day. One, Pyrus nivalis, the Snow Pear, is grown in eastern Europe and Asia Minor only for making perry.

The second species, P. communis, is much more important, since from it have come all but a very few of the 5,000 varieties that have been described in the literature of Pears from time to time. The oriental Pears supply several species of growing importance, chief among which is the Sand Pear, P. serotina culta. This is readily distinguished from the common Pear by its broad, ovate, long-pointed and sharply-toothed leaves; by flowers that appear before the leaves; and by fruits often Apple-shaped, russetted, and long-stemmed, and with calyces which drop with the fruit. It is found growing wild in Mongolia, and has spread into both China and Japan, where it is cultivated. From Japan the Sand Pear was taken to Europe, and from thence to America. The fruit is hard, long-keeping, and of very little value except for preserving. The species is, however, of importance to American growers on account of the hybrids which have sprung from crosses made between it and the common Pear, to give such varieties as Kieffer, Garber, and Le Conte. These hybrids have, from their oriental blood, a tolerance of heat, drought and light soils, to say nothing of "blight" resistance, so that, through them, Pear culture has been greatly extended into southern sections of the United States. Unfortunately, these varieties are not of the best, for the oriental Pear stamps its poor quality upon its offspring.

None of the other species from the Orient are of value so far as fruits are concerned, but because of the "blight" resistance of some they are receiving attention as stocks upon which to propagate the common Pear. American growers feel the need of better stocks for this purpose. At present their trees are usually propagated on seedling stocks imported from Europe. These are open to the objection that they form suckers freely, and disease is liable to find its way to the roots through the suckers. Trees on Quince are grown to some extent by amateurs; but the planting of dwarf trees has been discontinued in commercial orchards, because they are difficult to grow in the nursery and demand too close attention in the orchard, and because they often strike root above the stock and become standards.

Two forms of tree are grown, vase-shaped and central leader. In the case of the former no central leader is permitted to form, and the middle of the tree is open to light and air. It has the further advantage that, if fire-blight is severe, less damage is done by attack upon one of the limbs than upon the central leader of the other form of tree. On the other hand, the close-centred tree is considered to be better-suited to some conditions. It requires less detailed attention, and carries more fruits because the tree grows larger; and it comes into bearing earlier as a result of less pruning. This type shows the natural habit of the tree, one shoot ascending and the branches coming from it at various points along its length. When the tree has reached the desired height the leader is not permitted to go further. The central leader tree appears to resemble our pyramid form, except that it is not pruned anything like so severely.

Pruning is reduced to a minimum, largely because fire-blight, a kind of bacterial canker, which is the chief dread of the Pear-grower in America, is most liable to attack the soft shoots produced by severe pruning. Once the foundation of the tree has been laid, pruning consists of little more than thinning out, removing shoots that are not wanted rather than shortening those that are left. Earlier bearing is also induced by this system. Keiffer trees are, however, commonly tipped annually in some districts. In the Pacific coast States, especially California, a system of tying and spreading the branches has been developed, which has induced early fruiting with a minimum of pruning. The idea is to keep the branches "off centre" by tying to one side by means of string and a peg in the ground. With regard to the pruning of old trees, the author remarks that a tree past its prime must be restored to new vigour if it is to continue to bear profitable crops. Old trees frequently bloom profusely, but set few fruits, although the trouble is not one of pollenation. Usually it is lack of sufficient vigour to carry the fruits. One method of renewal is to cut off half the old spurs so that the energy of the tree may go into the remaining ones. Another procedure is to cut back severely to outside lateral branches so as to build up an entirely new fruiting top.

Pollenation is said to be of special concern to Pear-growers, not because there is more sterility among Pears than other fruits, but because the varieties most grown are commonly self-sterile. But a variety may be self-fertile in one locality and self-sterile or partially so in another. There are orchards composed entirely of Bartlett Pears, usually a self-sterile variety, which are apparently self-fertile, although the fruits have few seeds and are small.

Although this interesting little book is written from an American standpoint, it is quite likely that English gardeners could adopt some of the methods described. *M. G.*

GARDEN MANURES FOR JANUARY.

As the choice of a site for a fruit orchard or plantation will depend on a number of factors connected with the soil, climate, variety, etc., so will the system of manuring followed depend on similar factors, and both aspects of the subject are deserving of the most serious consideration, as error of judgment in either respect often leads to far-reaching results which are difficult to remedy.

It would be as difficult to point to any one type of manure as being ideal for fruit cultivation under all conditions as to assert that any one type of soil is the best for the purpose, nevertheless, the type of soil must necessarily be taken into consideration when formulating a system of manuring. Writing generally, most fruits do best in soils of a loamy texture; it may be a sandy loam or a clayey loam, but should not run to extremes in either direction. The soil and subsoil should be of such a physical character and depth that ample space is available for healthy root action, without which intensive feeding cannot be satisfactorily pursued. It is desirable that the surface soil contains sufficient humus to ensure a reasonable degree of natural fertility, at the same time soils containing an excessive amount of humus are not conducive to the production of fruiting wood. In the selection of a suitable soil it is well to use nature as a guide, for land which favours the growth of native fruits will, as a rule, possess the characteristics desired for the successful cultivation of our standard fruit crops.

But after every consideration has been given to the selection of the site, the preparation of the ground, and the planting and final establishment of the trees, it is probably not too much to say that fruit-growing, particularly on a commercial scale, is hardly possible, except some systematic form of manuring is practised. It is quite true that in exceptional cases the trees will make good growth and produce crops of fruits when no manure is applied, but even on such soils judicious applications of the proper fertiliser would improve the yield and quality and keeping ability of the fruits. It often happens that fruits from unmanured trees are lacking in one or more of these points, and the inferior flavour and keeping ability of some fruits may be due more to the fertilising factor than we realise.

A fruit tree, like other plants, requires a number of chemical elements for wood-making and fruit-producing, and unless it receives such in the right proportion there is likely to be trouble. It is undeniable, of course, that moisture, physical condition of the soil, the prevalence of insect pests and diseases and climatic conditions play their part in the general result; but an unbalanced food supply, whether that is naturally or artificially applied, is at the bottom of not a few failures to obtain the best results.

It follows, then, that a tree will require somewhat different treatment, both in quantity and composition of the manure applied, according to the age, size and productive capacity, the nature of the soil and climatic conditions, the particular kind of fruit grown, and even the market demands. During the early years of development the objective should be a rapid and healthy growth of well-formed trees which will reach bearing age and size in the least possible time. Other things being equal, a manure most likely to obtain satisfactory results in this respect should contain a fairly high percentage of nitrogen which should be applied at suitable times, in combination with an efficient system of cultivation and otherwise good growing conditions. It is not easy to lay down any hard and fast rule which will be applicable to all fruit trees under all conditions, as such factors as the quantities it will pay to apply must, in the nature of things, vary considerably with local conditions.

The amount of fertiliser a bearing tree will utilise profitably depends entirely on its condition and ability to bear fruits, and on the value of those fruits on the market, and while nitrogen plays an important part, particularly in the early growth of the tree, it should be borne in mind that a heavy crop of fruits takes large quantities of phosphorous and potash from the soil. The application of a complete manure is thus essential, and trees in good condition, bearing valuable crops of fruits, will require their fertiliser application to be increased over those in less good condition and bearing less heavy crops. Experienced growers regulate both the amount and composition of the fertiliser applied to the needs of the tree and to suit local conditions, and it is not due to chance that certain brands of fruits have become famous in world markets, but to the fact that the growers of these brands have studied the food requirements of their trees and applied fertilisers accordingly.

Whether a complete fertiliser is applied as a mixture in one dressing or in elemental forms at different times may be a matter of opinion, and excellent results have been obtained from both methods, but the time of application is governed by the solubility or insolubility of the fertilisers applied, and those who favour the use of calcium cyanide, basic slag and kainit should no longer defer application or satisfactory results cannot ensue in the coming season. *W. Auton.*

HOME CORRESPONDENCE.

The Colours of Flowers.—Returning home from a journey, I read the letter in your issue of November 10 (p. 375, Vol. LXXXIV), from your correspondent *H. H. Warner*, about the colours of flowers. I, too, received, through your office a copy of Ernst Benary's catalogue, with the very elaborate colour chart; this is very well done, but it does not seem to me to meet the difficulty raised by my previous letter, which is that of ordinary catalogue descriptions. If an amateur receives an English Rose, Iris or other hardy plant catalogue, he wishes a simple and clear, and as accurate as possible description of the flowers, colour. If for every Rose he should be obliged to turn to a colour chart, no matter how excellent and hunt out the exact shade of carmine—

---

* *The Pear and its Culture.* By H. B. Tukey, Acting Chief in Research, New York Agricultural Experimental Station. Illustrated. pp. 125. London: Kegan Paul, Trench, Trübner and Co. Price 7s. 6d. net.

8-5 Ra, or crimson, 9 Ra—he would soon become discouraged, and his Rose order would be smaller. A Rose may have several colours, but its general colour effect is what counts. Earl of Warwick and Radiance are both pink, but one who knows that the former is a warm, yellowish, "shrimp" pink will not plant it by the cold "true" pink of the latter. For this reason, I still think that some twenty or twenty-five colour terms might be agreed upon—"primrose" yellow, "gentian" blue, "mulberry" red, etc.—to assist the average amateur who has to order from descriptions. A paper with the influence of *The Gardeners' Chronicle* could easily carry this idea into effect. *A Roman Reader.*

Apple Ribston Pippin.—I see your correspondent, *E. C. M.*, Streetly, Staffordshire, in writing of Ribston Pippin Apple, in your issue of December 15, states: "I have seen it asserted by some authority that the Ribston Pippin comes true from seeds—can anyone confirm this statement? I cannot confirm it, but rather otherwise, for two of our best dessert Apples, *i.e.*, Cox's Orange Pippin, together with Cox's Pomona—came from a Ribston Pippin, which would suggest that it does not always come true from seeds. *Howard Grace, The Gardens, Brislington House, Bristol.*

Twin-flowered Cypripediums.—In my small collection, I have had this season two plants with one stem on each, each bearing two flowers; when the first appeared I thought it so unusual that I intended writing to Messrs. Sanders on the subject, when, however, a second one came, I arrived at the conclusion that there could be nothing very peculiar about it. In my case both flowers of both plants were perfectly developed and of normal size. They are both C. insigne var. Sanderae. *J. Percy Callard, The Priory, Monken Hadley.*

Memorial to the late Mr. John Cypher.—I have followed with interest the letters that have appeared in *The Gardeners' Chronicle* re the above, also your note on p. 403, in the issue of November 24, 1928. It would appear from the latter that any sum raised should be devoted in some form to one of the gardening charities. Having known the late Mr. J. Cypher for a considerable number of years—dating back to the old summer shows that used to be held in Regent's Park—and also having had the honour of his friendship, and the pleasure of judging his fine exhibits of plants and flowers at most of the great provincial shows, I feel that his memory would be the more suitably and permanently honoured if it could be associated with plants and flowers, and more especially with groups of these subjects. It is, I think, well-known and recognised that he did more for the artistic display of plants and flowers in this particular line than any one during his long career. I venture, therefore, to suggest that the interest of any sum that may be collected be devoted to these features at our principal horticultural exhibitions, and that medals bearing his name be awarded (over and above any prizes that may be offered by a society) to ornamental groups of flowering and foliage plants at (1) the Chelsea Show, (2) the Horticultural section of the Royal Agricultural Show, (3) Southport, (4) Shrewsbury, and, if funds permitted, (5) Edinburgh, and (6) Glasgow. If the Council of the R.H.S. would kindly undertake to administer such a scheme, the machinery is at hand, and success would be assured. *N. F. Barnes, Eaton.*

Plants in Flower in Mid-November in Cornwall.—Since our removal to Cornwall, at the end of September, I have been much interested in the number of wild and cultivated plants in bloom, and the following list of those still flowering (more or less) in mid-November will give an idea of the mildness of the climate. As soon as we were straight enough to allow of a little inspection of the country near us, we were rather astonished at the plants we saw quite unexpectedly in flower. On our own plot, which was a wood until it was cleared for ours and the neighbouring bungalows, we noticed common Bugle, Wood Violets, Bramble and Wood Sage, while in the neighbourhood were Ivy-leaved Toadflax, Gorse, Great Periwinkle and Sheep's Bit (Jasione). In gardens we noticed common Marigold, Sweet Scabious, Chrysanthemums in variety, Violas, Roses, Antirrhinums, single and double Stocks, blue Lobelia, Cheiranthus Allionii, white Marguerite, Fuchsia macrostemma globosa, Michaelmas Daisies (a few, mostly white-flowered), Lemon-scented Pelargonium, Escallonia macrantha, Winter Jasmine, and Polyanthuses; of these, the Pelargonium and Lobelia were in gardens near the Cathedral at Truro, and in several other gardens in the city I saw Fatsia japonica flowering well, as was, of course, its native relative, Hedera Helix, common in the hedges and on walls and trees. Dandelions, Daisy, Potentilla reptans and other wild plants are also still flowering. Among more interesting things may be mentioned Yucca gloriosa and Sternbergia lutea, Schizostylis coccinea, Mesembryanthemum tricolorum, Veronica clethroides and Veronica "Autumn Glory," Primula Juliae and P. pulverulenta, Scabiosa caucasica, Genista fragrans, Coronilla glauca, Hydrangea hortensis; with the exception of the Genista and Veronica "Autumn Glory," both of which are fairly common about here, each of the above plants was seen only in one garden, as also were Sidalcea malvaeflora Listeri and Berberis Darwinii. A very striking Kniphofia with thick, short spikes of yellow and fiery-scarlet flowers on stems about three feet high, grows in a cottage garden near here, and I shall be glad if anyone can tell me the probable species; I may add that the spikes are rather flat-topped, and about five inches long by four inches thick. But probably the most interesting of all is a fine plant of Abutilon (probably striatum), about six feet high, in an angle of the wall of a riverside cottage at St. Clements, near here, flowering freely. I am writing this in mid-December, and most of the plants mentioned are still in flower, in spite of the gales, heavy rains and several sharp frosts we have experienced during the last few weeks. *C. Nicholson, Nansgurthick, Tresillian, Probus, Cornwall.*

Royal Horticultural Society.—I feel sure that many Fellows will have read with surprise and amazement the suggestion made by Sir William Lawrence, in your issue of December 1, 1928, that after all the money that has been spent, and all the eulogies bestowed upon it, the new hall is not proving a suitable home for the Society. Further, it is suggested that considerable sums are likely to be spent at Wisley to provide further facilities for students. I submit, that with the excellent opportunities for horticultural education which exist in this country, it is not necessary for the R.H.S. to provide a School for Horticulture at Wisley, but if the Council desires to have students there, the numbers should be kept at a minimum; the Council is not justified in spending the Fellows' money in the way suggested. If the Council "has money to burn," I suggest that it might be expended in ways much more beneficial to the Fellows and horticulture as a whole. The directions in which such expansion might be carried out are as follows:—(1) The further financing or partial financing of collecting expeditions at home and abroad for the introduction or re-introduction of plants of merit. The meaning of the latter is obvious, but I would call attention to the excellent work of Mr. Hay, whose progressive spirit might be copied. Also I should, perhaps, amplify the former slightly. There are and have been scattered up and down the country in the gardens of amateurs many rare and beautiful plants which are, and have been, lost from time to time owing to the owners dying or being forced to leave their gardens. It should be the object of the Society to obtain specimens of such, so that they might be kept in continuous cultivation. (2) The *Journal* which is so valuable to Fellows who are rarely able to go to London or Wisley, should be expanded and issued more frequently. (3) Several gardens of small extent, which could be worked by one or two men on the lines of the alpine gardens in Switzerland, etc., should be established in different parts of the country so that plants which do not succeed in Wisley could be grown elsewhere, and new plants could be tried under as many different conditions as possible, and reported upon. (4) The distribution of plants should be enlarged and improved upon as being a distinct encouragement to horticulture, and not regarded as merely a means of getting rid of the Wisley surplus, *vide* 1927 report "as the garden becomes fully planted, the numbers available may be diminished." These suggestions are made here because so many Fellows who live away from London have no other means of expressing their approval or disapproval of the actions of the Council, but at the same time are not intended to belittle the work of the Council as shown by the wonderful progress which the Society has made in recent years, and also in the hope that Sir William was "flying a kite" with the object of obtaining the opinions of other Fellows. *E. B. Anderson, Hemyock, Devon.*

Record Potato Crops.—Referring to the note in your paper (Vol. LXXXIV, p. 381), regarding the above and stating that Mr. A. G. Adams had raised 835 lbs. of Potatos from 1lb. of seed, I do not understand how Mr. Adams was able to cut 1lb. weight of Potatos into 146 pieces, each with an eye. At the most, he would have to cut this number of eyes out of eight Potatos, and these would not be very large either, at an average of two ounces each. Was this weight produced in a competition and checked by any one as a Committee, in the same way as the competition is worked at Gainsborough, where the weight raised was 492 lbs. this year. At Gainsborough, the sets are obtained by the Committee, and no one knows what the variety is until a considerable time after the seed sets have been planted in the presence of a representative from the Committee, and who also attends when the Potatos are lifted, and checks each grower's produce on the spot. A limit of thirty pieces is fixed. You ask if anyone can beat the record, viz., 835 lbs. According to a note in Mr. T. W. Sanders' *Book of the Potato*, 1 lb. of Eldorado yielded 43 cwts., and also that in 1875, a Kentish gardener raised 647 lbs. of tubers from 1 lb. of cut tubers of the variety Eureka, but it does not state under what conditions these weights were obtained, and it is assumed that, at any rate in the case of Eldorado, they were obtained by cuttings from the tops. *H. Fawcett, Grimsby.*

FRUIT GARDEN.

PEAR CATILLAC.

If one were curtailed in the choice of a culinary Pear to a single variety, I venture to suggest that confidence would not be misplaced if Catillac was decided upon, for it is one of the best Pears for that purpose. According to Messrs. Bunyard's catalogue, it is of great antiquity, having been known before 1665.

The fruits are very large, roundish in shape, of a dull green colour turning to a yellowish-green after storing, with a brownish-red flush on the exposed side, which is more pronounced where the fruit has been in full sun. Its season is from December to April. When stewed the flesh may best be described as a deep pink, firm and of an excellent flavour.

The variety is a strong grower, succeeding as a standard or on north and east walls. It is fertile, has rather distinguished foliage of a very pale green colour, and is a regular cropper.

RASPBERRY HAILSHAM.

Raspberry Hailsham, or the Hailshamberry, was raised at Hailsham (Sussex) by Mr. Dann and is one of our finest autumn-fruiting Raspberries, producing fruits well into November during an "open" season. We gathered a small dish here so late as November 13.

It is a vigorous grower, provided it receives the correct cultural treatment, *i.e.*, cutting it to the ground in the spring, and I should like to emphasise this, for last year, as an experiment, we left the previous year's canes on a percentage of the plantation, and the result was neither profitable nor gratifying, except as an experience.

The fruit is very large, round, and of a rich crimson colour. The flavour is excellent and the foliage large and handsome, thoroughly protecting the fruits. *T. Wilson, Moreton Paddox Gardens, Warwick.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

AT the meeting held on Friday, December 14, 1928, the members of Committee present were Messrs. H. Astley Bell (in the chair), J. B. Adamson, A. Burns, B. Collins, A. Coningsby, D. A. Cowan, J. Evans, A. Keeling, D. McLeod, W. J. Morgan and H. Arthur (Secretary).

FIRST CLASS CERTIFICATES.

Brasso-Cattleya British Queen var. Renown. A large flower of good form and even colour, the fringed lip having a band of white, the throat being yellow. *Oncidium Boissyeana* (*varicosum Rogersi* × *Forbesii*). A large flower of the varicosum type, bright yellow, the inner segments being barred with chocolate-brown. Both from J. B. ADAMSON, Esq.

AWARDS OF MERIT.

Cypripedium Anita var. exquisita; *C. Alpha var. magnifica*; and *Odontioda Enterprise* (*parentage unknown*), from J. B. Adamson, Esq.

Cymbidium Matador (*Tracyanum* × *Schlegelii, Fowler's var.*), and *Cypripedium Queen Mab var. Ariel.* From Mrs. BRUCE and Miss WRIGLEY.

Cymbidium Doris var. maculatum, from the Hon. G. E. VESTEY; and *Vanda coerulea gigantea*, from Mr. JOHN EVANS.

READING AND DISTRICT GARDENERS'.

THE final fortnightly meeting of the autumn session was held in the Abbey Hall on December 17, 1928, when there was a large attendance, presided over by Mr. H. Reeves. A lecture entitled "Vegetables for Exhibition," was given by Mr. A. W. Gower, The Gardens, Calcot Grange, a well-known and most successful exhibitor of vegetables. In his opening remarks, he stated that his subject was a very wide one and therefore he could only deal with those kinds which are essential and necessary for a competitive collection of vegetables of nine kinds and which are given eight or seven points in the Royal Horticultural Society's *Code of Rules for Judging*. In the growing of vegetables for exhibition the chief essential is the preparation of the soil, which Mr. Gower dealt with very fully, also seed sowing, transplanting, and feeding. The vegetables dealt with were Onions, Leeks, Celery, Carrots, Cauliflowers, Potatos, Peas, Tomatos (eight points) and Runner Beans (seven points). In conclusion, suggestions were given as to the arrangement of collections and the preparations of the various specimens.

There was very keen competition in a class for three dishes of Potatos, the tubers being firm and of excellent colour for so late in the season. There were ten entries, and the first prize was awarded to Mr. E. BLACKWELL, The Gardens, Foxhill, Reading; second, Mr. A. H. FULKER, The Gardens, Elmhurst, Reading; third, Mr. A. E. KIRBY, Amity Road, Reading. In the non-competitive section, Mr. E. BLACKWELL received an Award of Merit for three vases of large Japanese Chrysanthemum blooms, while Mr. F. TURNER, Southview, Calcot, showed some good blooms of the yellow form of Chrysanthemum Madame Oberthur.

PROFESSIONAL GARDENERS'.

AT the meeting of this Association, held at the Victoria Hotel, Leeds, early in December, Mr. J. T. McCormack, who occupied the chair, reported the formation of a vigorous new branch at Harrogate, with about twenty members. Propaganda is going on in several other centres and much progress is being made. A number of new members were enrolled, and much business of importance was discussed, after which Mr. T. Hooker delivered a lecture on "Orchids."

Mr. T. Hooker, who has had several valuable collections under his care, is a recognised authority on the cultivation of all classes and genera of the Orchid family, and gave a highly interesting and instructive address, dealing principally with Cattleyas, Cypripediums, Dendrobiums and Odontoglossums. He also touched briefly on many other sorts, and an interesting and helpful discussion ensued, Mr. Hooker answering many questions and imparting much sound advice.

Obituary.

Lord Lambourne.—One of the best known and most popular of personages has passed away at the advanced age of eighty-one years—Lord Lambourne. As a Guardsman he was ever a favourite, and the robust good humour that won him so many friends in his earlier years served him well in later life. When, as Colonel Mark Lockwood, he sat in the House of Commons, his fellow members were always delighted to hear him. His witticisms and smiles often saved a delicate situation when cogent arguments were unavailing. Lord Lambourne was a great lover of animals and of gardening, and for these objects of his affection he was always ready to work and use his great influence. For many years he was Vice-President of the Royal Society for the Prevention of Cruelty to Animals, and from 1917 to his death he was President of the Royal Horticultural Society, a position of which he was unfeignedly proud. Although never a great gardener, Lord Lambourne became a great personality in the horticultural world—a personality that could neither be avoided nor ignored. It was his delight to escort the King and Queen through the great Chelsea Shows, and his jokes would bring laughter to the Royal party; but, equally, a nurseryman's assistant would receive the same old-fashioned courtesy and be set at ease by some witticism or quaint observation. He was greatly loved by the members of the R.H.S. Council, and, indeed, by all Fellows of the Society, exhibitors and pressmen. There may have been greater Presidents of the Royal Horticultural Society, but none more liked and loved. He was get-at-able by all, and hail-fellow-well-met to peer and peasant, gardener and king. And yet, through all his jollity of manner, Lord Lambourne preserved that touch of autocracy so long associated with "baron and squire and knight of the shire." For some time past he had been in failing health, consequently during the past year or so his breezy open-airness suffered a partial eclipse, and he was at one time afraid he might not be able to lay the foundation stone of the New Hall; fortunately, this pleasure was not denied him, and when he escorted Princess Mary to the dais on the occasion of the opening of the hall, he did so with a gladness that showed how greatly he had set his heart upon attending this notable function in the history of the Royal Horticultural Society. He was doubtful as to the wisdom of building the new hall, but after the Council had decided upon the scheme Lord Lambourne never faltered in his loyalty to the Council over which he presided so ably and genially. In his garden at Bishop's Hall, Romford, Lord Lambourne loved to grow both old-fashioned and uncommon plants, proof that his affection for the conditions of his early years was not an obsession; indeed, in many ways Lord Lambourne continued youthful, and every novelty in plant and flower received his due consideration. He maintained his old-fashioned love for a "button-hole" to the last, but whereas he was wont to wear a full-sized Carnation, he had, since the death of his wife, worn only a sprig of Myrtle. In Masonic circles Lord Lambourne held the high position of Provincial Grand Master of Essex, and he took a great interest in various Masonic charities. His chief business association was with the London and North Western Railway, of which he became a Director many years ago, long before its incorporation with the L.M.S.

THE LATE LORD LAMBOURNE.

The funeral service took place at Lambourne Church, on Monday last, the Bishops of Chelmsford and Barking officiating. The body was borne from Bishop's Hall to the Church on an estate farm wagon, and men of the Coldstream Guards acted as pall bearers. The attendance was very large, and in addition to the family mourners, included many notable people representing the House of Lords, the House of Commons, the County of Essex, Freemasonry, and various Societies. Horticulture was represented by Mr. C. T. Musgrave, Mr. George Monro, Mr. G. W. E. Loder and Mr. F. R. Durham from the Royal Horticultural Society; and Mr. Courtney Page from the National Rose Society. Those who attended to pay tribute to the regard in which Lord Lambourne was held, were so numerous that the majority could not gain admittance to the Church, consequently the Bishop of Chelmsford gave his address at the graveside. Floral tributes were many and beautiful, and included one of red Carnations from Her Majesty Queen Mary. Memorial services were held at St. Margaret's, Westminster, at Chelmsford Cathedral, and at St. Nicholas's Church, Chelmsford. At the service at St. Margaret's, the King was represented by Viscount Gage; the Prince of Wales by Sir Godfrey Thomas; and the Duke of Connaught by Lt.-Col. Sir Malcolm Murray. Horticulture was also represented at the service by Sir William Lawrence, Sir Jeremiah Colman, Sir David and Lady Prain, Mr. Gerald Loder, Dr. A. W. Hill, Mr. T. Hay, Mr. Mark Fenwick, Mr. E. A. Bowles, Mr. Scrase Dickens, Mr. R. W. Wallace, Mr. Noel Sutton, Mr. H. H. Thomas, Mr. W. B. Cranfield, Mr. F. J. Chittenden, Surgeon Lt.-Com. A. T. Dalby and Mr. A. Simmonds. Out of respect to their late President, the Council of the R.H.S. abandoned the exhibition fixed for January 1.

I have been disturbed to find in the daily press a tendency to treat Lord Lambourne's life as a joke. He was a very wise man, and his notable characteristic was that he invariably played the game and expected others to do the same. Wire-pulling he abominated, and was the kindest and most hospitable of friends. He had no use for the professional politician and for men who disputed the decision of the judges in agriculture, horticulture and elsewhere. An ardent lover of the good old times he was at first doubtful about the success of the New Hall; when it was completed he admired the interior, while frankly disliking the exterior, of which, however, his Christmas card this year showed a view. He was in no sense an "expert" horticulturist, as the daily press avers, but just as he had an eye for a good horse or a fine *objet d'art*, he knew a good florist's flower. Although in the later years he became interested in a few conspicuous species, such as Rhododendron and Magnolia, the richly-coloured garden forms of flowers appealed most to him. Many fine garden plants have been named after him, Carnation, Oriental Poppy and Dahlia. He told me that he thought the Dahlia Society's Show was the finest display of colour he had ever seen, while the late Sir George Holford's Hippeastrums always won his ardent admiration. With his two big houses he was a very lonely man after the death of his wife and he would spend much time reading memoirs in French—he lived two years as a young man at Angers—and English. The tender care shown him by Miss Lawrence was a great comfort to him. Miss Lawrence is a keen gardener, and the tradition of Bishop's Hall will be kept alive by those two fine Dahlias—Mabel Lawrence and Lord Lambourne. *W. L.*

Ernest Horton.—It is with the deepest regret that we record the death of Mr. Ernest Horton. Although his friends knew his malady to be hopeless, the news of his death on December 14 last was in the nature of a shock, for until quite recently Mr. Horton had been busily engaged on his many affairs, full of his accustomed energy and enthusiasm. It is no hackneyed phrase to state that horticulture is the poorer for his passing. It is one of the paradoxes of life that while the results of his work were well-known to a vast multitude of gardeners of all classes, comparatively few, outside trade circles, knew Mr. Horton even by name. But the trade and his other friends well knew that Ernest Horton was the soul and driving force of the enterprising firm of Messrs. Bees, Ltd. His earlier gardening experience was obtained in various private gardens in the north, and he went to Kew from Croxteth Hall, Lancashire, in 1899, becoming seed-collector the following year. Then, feeling that in the commercial side of horticulture lay his real work, he found employment with such well-known firms as Messrs. James Veitch and Sons, Messrs. Backhouse and Sons, and Messrs. Clibrans, Ltd. He joined the staff of Messrs. Bees, Ltd., when that firm was started, as assistant manager, and in due course became general manager. In some circles he was, perhaps, looked upon as the stormy petrel of the horticultural trade, but this impression was created rather by his impetuous and go-ahead nature. He was always doing things and wished others likewise to do things, particularly for the benefit of the trade he had so much at heart. He rightly had an intense belief in the power and value of advertising, and endeavoured to imbue others with his enthusiasm. Not only was Mr. Horton a successful business man, he was a facile and forceful writer, and his colour photographs reached a high standard of merit. While his business affairs often took him fairly far afield, it was at home that Mr. Horton found his greatest pleasure, for he was essentially a family man. He has left a widow, three sons and two daughters, to whom we offer our most sincere sympathy and condolences.

Francois de Laet.—We regret to learn of the death, on December 25 last, of Francois de Laet, the well-known Cactus specialist, of Contich, near Antwerp. M. de Laet was born at Contich on October 7, 1866. He has left two sons, his wife having pre-deceased him. Better-known on the Continent, where Cactus growing is more the vogue than in this country, his reputation was, nevertheless, world-wide, and horticulture is the poorer for his death.

M. Pernet-Ducher.—We regret to learn from the French horticultural press of the recent death of M. Pernet-Ducher, the great French Rose-grower, who gave to the world the race of Roses known as Pernetiana. The first of this race, known as Soleil d'Or, was raised in 1900, and was said to be a cross between Persian Yellow and a variety named Antoine Ducher. Soleil d'Or is now seldom grown, but its production had the effect of infusing fresh blood into garden Roses, and was responsible for enlarging very greatly the range of Rose-colourings. In 1908, M. Pernet-Ducher produced The Lyon Rose, which was a cross between Persian Yellow (through Soleil d'Or) and the best of the Hybrid Teas, and marked a considerable step forward. Working on the same lines with ever-growing success, M. Pernet-Ducher produced in 1910 the well-known Rayon d'Or, and a year or two afterwards the ever-popular Madame Edouard Herriot, named after the wife of the Mayor of Lyons, where the famous Rose nurseries are situated. M. Pernet-Ducher retired from active business some years ago, but continued to take a keen interest in the subject of his life's work. Few horticulturists can have accomplished, in a single life-time, so much pioneer work on a single race as M. Pernet-Ducher achieved in the realm of Roses, and it is fitting that his name should be enshrined in the name of the new race with which he has endowed Rose-lovers all over the world.

ANSWERS TO CORRESPONDENTS.

Arbutus Failing.—*A. J.* The Arbutus leaves are free from fungus disease. Some bacteria are present in the blackened areas, but are probably saprophytic. The damage is due to some physiological factor, and may be the result of spray damage. Arbutus prefer a well-drained, rich compost and it will be advisable to see that the plants are provided with such. It is recommended that a mulch of well-decayed leaf-mould and some farmyard manure be given to the plants now, and a dressing of sulphate of potash applied in spring.

Begonia Leaves Discoloured.—*A. C.* We have examined the Begonia leaves and find no trace of disease to account for their discoloration, consequently, we consider the injury must be due to some adverse cultural condition, probably to drops of very cold water falling upon them.

Begonias and Cyclamens Infested.—*P. J. B.* The foliage you sent us was badly infested with Begonia mite, which may be eradicated by dipping the plants in, or spraying them with, a Nicotine solution.

Celery Damaged.—*H. T.* The damage to the Celery is probably due to millipedes. Remedial measures include (1) trapping by means of hollowed-out Mangolds or Beetroots placed beneath the soil, and examining them every other day during the time the crop is in the ground; (2) dressing the ground with commercial naphthalene (two to three ounces to the square yard)—better results will follow if this material is watered in or applied prior to rain; and (3) a heavy dressing of lime to the soil during digging operations.

Chrysanthemum Unhealthy.—*J. M. S.* The Chrysanthemum shoots are not attacked by any fungus disease. There may be trouble, however, at the base of the plant. The condition of the flowers suggests unhealthy root action, or may be due to the plant having experienced cold draughts of air, or water dripping from the roof of the house.

Delphiniums.—*V. T.* Five good and cheap varieties are Persimmon, Rev. E. Lascelles, Mrs. Creighton, King of Delphiniums and Duke of Connaught. Five more expensive varieties are Sir Douglas Haig, Harry Smetham, Mrs. W. Wells, Lizzie van Veen and Millicent Blackmore.

Fallen Timber.—*T. R.* In the absence of express agreement to the contrary, windfalls of sound timber belong to the landlord, but windfalls of trees which are not timber and of decayed timber trees belong to the tenant. Your case, however, is governed by the express clause in the lease, and if the fallen trees are timber, they are the property of the landlord.

Gardener's Wages During Illness.—*X. Y.* A gardener receiving relief from the State Insurance scheme cannot claim wages from his employer, but it is usual for the employer to make up the difference between the State allowance and the wages.

Glassiness in Apples.—*W. L.* The Apples are affected with the physiological trouble known as "glassiness," which is caused by the cells of the flesh near the skin becoming overcharged with water. There is no known cure for the trouble, and it rarely happens that many fruits on a tree are so affected.

Irises and Chrysanthemums.—*V. T.* A few varieties of Iris in yellow and reddish shades are Prosper Laugier, Princess Victoria Louise, Pelopidas, Porsenna, Mrs. Nandy Hoskins, Medrano, Maori King, Mrs. King, Helvetia, Ed. Michel, Caprice and Anoba. A selection of Chrysanthemums for your purpose should include: Pale pink—Jacky, Pink Delight and Uxbridge Pink; Yellow—Knaresborough Yellow, Mayford Yellow and Daffodil; Red—Crimson Circle, Red Almirante and Red Ensign; Brown—Mrs. Jack Pearson, Almirante and Harvest Glory; Maroon—Minstrel and Dick Barnes; Mauve—Mrs. James Scalley, Silver Queen and Dolly Reeves; Cream—Cranford Cream, Perle Chatillonaise; Early-flowering Singles—Donald Wells, Doreen Woolman and Richard Holding.

Licence for Gardener.—*G. W.* If the gardener is in the sole employ of the employer, a licence is necessary under the Inland Revenue Act, 1869.

Lichen on Apple Trees.—*L. B.* Your best course will be to spray your trees with one of the winter washes, so as to cleanse the twigs and branches from lichen and moss. The work should be done before the end of January.

Names of Fruits.—*H. W. R.* 1, Alfriston; 2, Harvey's Wiltshire Defiance; 3, Adams's Pearmain; 4, Old Hawthornden; 5, Beauty of Kent; 6, Lord Burghley; 7, Court of Wick.—*T. H.* 1, Claygate Pearmain; 2, Alfriston; 3, Pear Winter Nelis.—*V. E. W.* 1, Newton Wonder; 2, Aromatic Nonpareil; 3, Smart's Prince Arthur; 4, Radford Beauty.—*G. B.* 1, Beaumann's Reinnette; 2, French Paradise.—*A. L.* Easter Orange.

Names of Plants.—*A. S. B.* Pyrus Aria—*J. G. St. L.* 1, 2, 3 and 4, Skimmia japonica, male and female forms; 5, Iberis sempervirens Garrexianum; 6, Betonica spicata variegata; 7, Euonymus japonica variegata; 8, Jasminum officinalis; 9, not recognised; 10, Corydalis lutea; 11, Sedum sp., send in flower; 12, Veronica speciosa. *W. L.* 1, Photinia serrulata; 2, Euonymus radicans var. variegata; 3, Euonymus Sieboldianus.—*F. J. T.* Albizzia lophantha. *H. W. A.* Datura Stramonium.

Sowing Azalea japonica Seeds.—*V. T.* According to their quantity, you may sow the seeds in pots, pans or seed-boxes, using a compost of fine sandy peat made moderately firm. It is best to water the soil in the seed pots with a fine-rosed watering-can a few hours before sowing the seeds. The fine seeds should be evenly distributed over the surface and should be covered with a sprinkling of sand. Stand the pots in an ordinary greenhouse, cover with a piece of glass, and give shade until germination takes place.

Woolly Aphis on Apple Trees.—*F. W.* We have no experience of the use of carbide of calcium inserted in the ground as a cure for woolly aphis on the roots of Apple trees; but bi-sulphide of carbon is used in that way, as it is very volatile and inflammable, it should be used quickly and carefully.

REMARKS.—Chrysanthemums are gradually decreasing in quantity, although spray and disbudded blooms of white sorts are still sufficient to meet present requirements. Supplies of coloured varieties are somewhat shorter, but some good yellow and bronze blooms are still on sale. Negoya and Winter Cheer are the best lines in spray Chrysanthemums. Carnations have returned to a more nominal figure, while Roses are insufficient in spite of the high prices. Arums (Richardias) are also on the down grade. Lilium longiflorum supplies are short. Daffodils are on the increase and much finer in quality, as also are Tulips, which now include some very fine blooms of William Copland, King of the Yellows, Yellow Prince, Thomas Moore, La Reine and Brilliant. More Iris tingitana blooms have been greatly welcomed, together with white Freesias and white and yellow Narcissi from the Channel Islands. Single Violets have been very limited in quantity for some days past. White and mauve Lilac and Prunus triloba are of improved quality—the best received this season. Small consignments of Tulips and Lily-of-the-Valley are now arriving from Holland. In the French department, Anemones, Ranunculus, white and yellow Narcissi, Marguerites. Marigolds and single Violets, also a few bunches of Parma Violets, are the most prominent lines.

REMARKS.—There has been an average amount of business transacted for the time of year, the week following the Christmas holiday being always on the quiet side. Moderately large supplies of hothouse Grapes have been available, and in response to an active demand from Scotland for the New Year celebrations, values have been maintained well. The Apple market is quiet and prices all round are inclined to be lower. A few English Cox's Orange Pippins are selling well, and this variety will probably continue popular while the fruits arrive in good condition. There has been a slakening in the trade for Pears, and both English and imported Doyenné du Comice being offered at lower prices. The early part of this week has seen a keen demand for Asparagus, but it is likely that prices will be easier later. The earliest shipments of fruits from South Africa are now arriving, this week's consignment consisting chiefly of Peaches, Apricots and Plums.

The trade for forced Peas, Beans and Potatos is moderate at the comparatively high prices that are ruling. Salads, mainly from France, are selling well, Lettuce in particular being rather expensive. Mushrooms have improved somewhat in price since the week-end, and the position in that section is now more stable. Forced Rhubarb is arriving and selling fairly well. The old Potato trade is steady

GLASGOW.

Owing to the Christmas holidays in the south, cut flowers were scarce during the past week and prices displayed an irregular tendency. Chrysanthemums, which are nearing the end of the season, depreciated both in quality and quantity, with the result that top grades commanded high values. Ordinary quality sold as follows: Balcombe Beauty and Favourite, 1s. 6d. to 2s. 6d. for 6's; Tuxedo, 1s. 6d. to 2s.; Jean Pattison, 1s. 6d. to 1s. 9d.; Sunshine, 1s. 3d. to 1s. 6d.; and Winter Cheer, Wilcox and Baldock's Crimson, 1s. to 1s. 6d. Hyacinths were worth from 9d. to 1s. 6d for 3's; Golden Spur Daffodils, 1s. 3d. to 2s. for 6's; Thomas Moore and Montressor Tulips, 9d. to 1s., and William Copeland, 1s. 6d. to 2s.; Carnations, 6s. to 10s. per dozen; Roses, 6s. to 8s.; Richardias, 6s. to 7s. per bunch; Lily-of-the-Valley, 2s. to 2s. 6d.; Narcissus, 2s. 6d. to 4s. per dozen bunches; Mimosa, 12s. per cane; and Smilax, 1s. to 2s. per bunch.

The end of the year imports of fruits were heavy, and as the demand was keen, prices advanced appreciably. Apples were in good condition and met with a ready sale at the following values:—Jonathan, extra fancy, 11s. to 11s. 6d. per case; fancy, 9s. 6d. to 10s. 6d.; Delicious, extra fancy, 13s. to 13s. 6d.; fancy, 12s. to 12s. 3d.; Spitz, extra fancy, 10s. 6d. to 11s.; fancy, 9s. 6d. to 9s. 9d.; Newtowns, extra fancy, 13s. 6d. to 15s.; fancy, 12s. 6d. to 14s.; York Imperial, 26s. to 27s. per barrel; Winesap, 32s. to 34s.; Albemarle Pippin, 45s. to 50s.; Greening, 34s. to 35s.; and Stayman, 23s. 6d. to 30s. Winter Nelis Pears were worth 18s. 6d. to 21s. 6d. per case for Oregon and Californian fruits, and 13s. 6d. to 17s. for Washington. Jaffa Oranges sold at 15s. to 15s. 6d. for 120's; 16s. to 17s. for 144's; 16s. 6d. for 180's; 16s. to 16s. 6d. for 240's; Murcia, 16s. 6d. to 20s. for 240's; 17s. 6d. to 20s. for 300's 15s. 6d. to 17s. for 360's; 17s. to 19s. 6d. for 504's ordinary; Valencia, large, 27s. to 40s. 27s. 6d. to 32s. 6d. for 714's; 15s. to 20s. 6d. for 200's and 240's; 15s. 6d. to 18s. 6d. for 300's; 15s. to 16s. for 360's 15s. 6d. to 16s. 6d. for 504's. Mandarin were worth 1s. 6d. to 2s. per tray. Hothouse Grapes made 2s. 6d. to 3s. 6d. per lb. for black, and 5s. 6d. to 6s. 6d. for Muscats. Lemons, 18s. per case of 300.

Vegetables were scarce, Cauliflowers selling at 5s. 6d per dozen, and Mushrooms, 2s. 6d. per lb.

GARDENING APPOINTMENTS.

Mr. J. Harvey for the past thirty years gardener at Frampton Court, Dorchester, as gardener to Field-Marshal LORD METHUEN, Corsham, Chippenham, Wiltshire.

Mr. William Molyneux, previously foreman at Edenhurst, Sevenoaks, at Tranby Croft, Hull, and Everlands, Sevenoaks, and recently gardener to Major LAMBARD, Bradbourne Hall, Sevenoaks, as Gardener to Sir CHARLES OAKLEY, Bart., Frittenden House, Staplehurst, Kent. (Thanks for 2/6 for R.G.O.F. Box.—EDS.)

Mr. H. Wilson, for the past fourteen years gardener to ISAAC SMITH, Esq., late of Hazlewood, Silverdale, Lancashire, as gardener to the UNIVERSITY OF CAPE TOWN, Groot Schuur, Dondebosch, Cape Town, as from May, 1929. (Thanks for 2s. 6d. for the R.G.O.F. Box.—EDS.).

Mr. E. Humphries has been appointed to succeed Mr. S. Brown as gardener to RICHARD CARTWRIGHT, Esq., Aynho Park, Banbury.

Mr. S. Bowler, pleasure ground foreman at Ford Manor Gardens, has been appointed gardener to Mrs. CAMBELL BANNERMAN, Hanton Court, Maidstone.

The National Institute of Agricultural Botany.

WHEN this institution was founded at Cambridge, in 1919, high hopes were entertained by its promoters. The eyes of plant breeders had long been fixed on the great station at Svalof, in Sweden, where the labours of Nihlson-Ehle to produce improved varieties of farm crops by scientific methods had been rewarded by repeated successes, and even growers here had come to acknowledge the outstanding merits of Swedish varieties of Wheats and Oats. The Cambridge institution, confessedly, was modelled on Svalof; it was to be a fruitful blending of the scientific skill of Sir Rowland Biffen, with the practical business organisation needed to grow on and market the improved plants to be produced by the plant breeders. Now, at Svalof there are really two administrative units, one purely scientific, producing improved varieties in small lots; the other a business establishment equipped with a modern plant for cleaning and grading grain in bulk, run in conjunction with a number of seed-farms. The scientific, however, controls the business department, in the sense that the latter cannot handle varieties not approved by the former, which at the same time tests and guarantees every parcel of seeds issued by its partner. A remarkable feature of the business end of Svalof is the size and completeness of the seed-cleaning machinery, the capital value being upwards of £30,000. It is, indeed, impossible to conceive any really effective means of distributing good seeds that do not include costly machinery for cleaning and grading; for every practical man knows how rapidly a pure pedigree strain of seeds deteriorates if left to the tender mercies of the ordinary threshing machine. We are glad, therefore, to learn from the report of the N.I.A.B. that has just been issued, that funds are now available for the erection of buildings and plant which will enable it to undertake an indispensable branch of the business, and thus complete the model of the parent Svalof. The Institute will never reach its full development until seeds with a Cambridge guarantee of purity and trueness of variety appear on the market. Hitherto, it has been constrained to leave the control of growing on and marketing largely in the hands of the trade, and thus, in a large degree, the seeds have failed to reach the farmer directly. The Swedish institution is in the happy position of being permitted to enter the seed market freely; here the deservedly commanding position occupied by the leading seed firms precludes direct means of access, but some way by which benefits (to which, be it noted, the tax-payer has contributed), will reach the agriculturist, will, doubtless, be devised without any undue interference with vested interests. It is not intended, however, to suggest that the work of the N.I.A.B. has hitherto been nugatory; on the contrary, it has been engaged on useful work. With a view to settling the best varieties of crops for use in different parts of the country, the Institute for some years past has been engaged on a number of schemes of great practical utility. It has established a number of crop-testing stations, and as a result much reliable evidence has been gathered in relation to a number of crops. Again, the Institute controls the Potato research testing station at Ormskirk, where, *inter alia*, under the guidance of Dr. Salaman, the Synonym Committee has settled many vexed questions of importance to horticulturists. In the report under notice, mention is made of a remarkable scientific development in relation to Wart Disease of the Potato. One of the objects with which the Ormskirk Station was founded was to verify the claims made of resistance to the disease by the breeders of new varieties, a task which hitherto has entailed two years' trial in disease-infested soil. But in July last Miss Glynne, of Rothamsted, discovered a method by which the resistance of a variety can be settled in the laboratory in three weeks. That the method can be applied to the Ormskirk work has now been proved by the staff there. It is also of interest to learn that the recently discovered methods of hastening the sprouting of Potato seed sets by the use of certain chemicals have given good results at the Lancashire centre. Altogether, the last report of the N.I.A.B. is the most encouraging that has yet appeared.

The Gardeners' Chronicle Almanac, 1929.—In accordance with our usual custom, we present our readers with an Almanac in this, the second issue of the New Year. The list of horticultural meetings and exhibitions is as complete as this early date, and space, will allow. Some dates have been received too late for insertion, but these, and others received later, will be included in due course in our "Appointments for the Ensuing Week." Secretaries will greatly oblige us by kindly sending dates of their fixtures so soon as they have made their arrangements for 1929.

Gardeners' Royal Benevolent Institution.—The eighty-ninth annual general meeting of the Gardeners' Royal Benevolent Institution will be held at Connaught Rooms, Great Queen Street, London, W.C.2, on Thursday, January 24, 1929, at 3 p.m., for the purpose of receiving the Report of the Committee and the Accounts of the Institution (as audited) for the year 1928; electing officers for the year 1929; and for the election of twenty annuitants on the funds. The chair will be taken by Leonard Sutton, Esq., C.B.E., Chairman of Committee, at three o'clock. The poll will be opened at three o'clock and closed at four o'clock precisely.

Captain F. Kingdon Ward.—Looking very fit and well, Captain F. Kingdon Ward has just returned from his eighth plant-hunting expedition in Asia, and brought with him the manuscript accounts of his travels, together with numerous photographs. We hope to resume the story of his journey and discoveries in our next issue. Meanwhile, Captain F. Kingdon Ward has only a few weeks in which to prepare for his next trip to the East.

Legacies to Gardeners.—The late Major Hubert George Howard Galton, of Hadzor House, Droitwich, who died on September 21, left £150 to his gardener, Mr. W. B. Smith.—The late Mr. Walter Maddoc Simpson, of York Road, Birkdale, who died on October 29, left £100 to his gardener, Mr. Richard Sefton Robinson.—The late F. J. Yarrow, Esq., of Abbey Road, St. John's Wood, left his gardener, Mr. A. Robertson, £1,000, and Mrs. Robertson, £100.—The late Mr. William Higginbotham, of Palatine Road, West Didsbury, Manchester, who died on November 5, left £50 to his gardener, Mr. John Bailey.—The late Mr. Kenneth Eldmann Chalmers, of Blackbrook, Bickley, who died on November 9, left £250 to his gardener, Mr. Albert E. Gibbs.—The late Lady M. A. James, of Springfort, Stoke Bishop, Bristol, left £75 to her gardener, Mr. Alfred Charles Fletcher.

Belgian Florists' Banquet.—On Saturday, December 15, 1928, the annual florists' banquet took place at 7.30 p.m. in the rooms of the Ermitage Hotel, in Brussels, Belgium. In a country where flowers take such an important position, not only in the affections of the people, but also in their economic life, such an event is naturally of some importance, and it was a large and distinguished company which sat down to table, the President of Honour being M. Odon Warland, the famous cigarette manufacturer and horticultural enthusiast. There were also present certain foreign guests, including the President and Vice-President of the Paris Florists' Union. With the champagne, the speeches began, the opening toast—the President—being proposed by M. Paul Marin, the President of the Society, the Union des Fleuristes de Belgique.

A New Garden in Fleet Street.—In the midst of the struggle which is now being made by a few public-spirited people to preserve the few remaining gardens and squares left in London, it is cheering to hear of any additions to the scanty acreage, however small, and it is pleasant to be able to record that in Mitre Court, on the south side of Fleet Street, a small piece of ground is being made into a garden. The land is the property of the Inner Temple, whose buildings it adjoins, and it is now being carefully turfed over and planted with small trees. In the centre of the turf is a flower bed, surrounded by a narrow, paved walk, and this will no doubt be planted in due course with bedding plants according to the season. When the trees have attained to some size, and the turf is settled, the tiny garden will do much to relieve the austerity and starkness of the old court. It is greatly to be hoped that the heavy iron railings, between five and six feet in height, with which the ground is now surrounded, will be replaced by a low paling sufficient to preserve the turf from damage, but enabling passers-by to obtain an uninterrupted view of the garden.

Fédération Horticole Professionelle Internationale.—The next meeting of this Fédération will be held in London during the period of the

Chelsea Show, which latter event is to take place on May 22 to 24, 1929. Among the subjects for discussion will be: Overproduction and means of avoiding it; The international transport of horticultural commodities; Phytopathology and importation of plants; The Rome International Institute of Agriculture; Dumping; and The possibility of improvements in the arrangements for national and international horticultural exhibitions. The date and place of the next year's Conference will also be fixed this year. It will be a great pleasure to British horticulturists to welcome the foreign delegates to these shores, and show them whatever progress may have been made in British horticulture since they were last here, besides doing all that is possible to make their stay a pleasant one. "Chelsea" weather is notoriously unreliable, but it is to be hoped that on this occasion at least there may be a sunny and comparatively warm period.

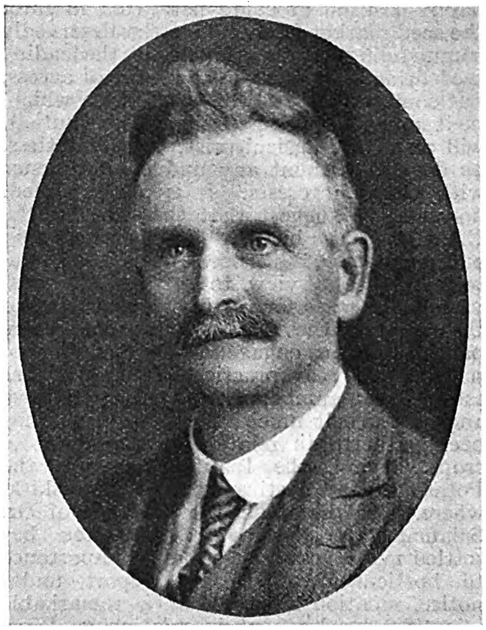
Weather Records in 1928.—During the past year, several new weather records have been set up. In the midlands, January was the wettest January for 137 years. On February 11, at Liverpool, a gale reached the record velocity of 104 miles per hour, and the city experienced another severe gale on August 26. On the night of April 8-9, London experienced a record maximum temperature of 55°, while the Scilly Isles were visited by driving showers of sleet and snow. April of last year, at Edinburgh, was the driest for six years. In the London district June was the wettest and July the sunniest for the past six years. Edinburgh enjoyed more sunshine during September than in any month for twenty-two years. In the third week of October London suffered exceptionally severe gales, culminating in the tornado of October 22. On December 7, more sunshine was recorded at Kew than on any December day since 1881.

Park Employees and Unemployment Insurance.—A curious position has arisen in consequence of the decision of the Ministry of Labour classifying public park employees as agricultural labourers, thus depriving them of the benefits of unemployment insurance under the statutes. Nearly six hundred men in the employment of the Parks Department of Glasgow Corporation—gardeners and their assistants, bowling green and tennis court keepers, golf green keepers, park labourers and fencers, etc., are affected. Until October 3, these workers were considered by the Department as insurable, and as their contributions were regularly deducted from their wages, the Corporation has now lodged a claim for the refund of the money. It is understood that the Ministry will refund all contributions made during the past six years, and that these will amount to £4,000 in the case of the men, and to a like sum in the case of the Corporation.

Cornish Broccoli for Germany.—Mr. H. W. Abbiss, Horticultural Superintendent for Cornwall, in the course of a lecture which he gave at Bridge quite recently, stated that he would be leaving for Germany shortly with a view to finding markets in that country for Cornish Broccoli.

Azalea Exhibition at Ghent.—The Society known as the Belgian League of Azalea-Cultivators, which has its headquarters in Ghent, Belgium, organised on the Saturday and Sunday before Christmas an exhibition of flowers which can be forced into bloom for Christmas. Azaleas naturally took pride of place, but there were also large quantities of Cyclamens, and many foliage plants, such as Bromeliads, Dracaenas, Ferns, Anthuriums and Palms. The purpose of the exhibition was to make the Azalea and other winter-flowering plants more popular with the public, and in especial to demonstrate that the Azalea can be had in full flower by Christmas. Two large halls in the flower market were filled with the exhibits, which made a brave display in their warm, brilliant colours. Among notable persons who assisted at the opening ceremony were M. van de Weghe, the President of the League, MM. Pynaert, Spae, and A. De Smet, of the Belgian Chamber of Horticulture, MM. Delmotte and Duquesnoy, of the Ghent Horticultural Society, and M. de Wilde, the Ghent Director of Parks and Gardens. A number of awards were made to exhibitors, including a Gold Medal diploma to Messrs. Sanders, of Bruges, for Azalea novelties Memoria Sander and Erica Sander.

Mr. A. J. Hartless.—Like many another successful gardener, Mr. A. J. Hartless had the advantage of an early training under his father, in this case at King's Walden Bury, where Mr. T. J. Hartless was gardener for many years and retired only in 1921. On leaving King's Walden Bury, Mr. A. J. Hartless went to Aldenham, where he served for three years under Mr. Beckett before going to Kew. He took the usual courses of study at Kew and also attended land-surveying classes at Richmond, and sat successfully for the South Kensington horticultural and agricultural examinations, after attending courses at the Regent Street Polytechnic. At Kew, Mr. Hartless was for some time in the Arboretum Department, at a period when many large trees were lifted and transplanted; subsequently, he was employed in the rock garden, and these two experiences have been of great value to him in his present position. He next obtained a post in the Parks Department of the London County Council, and while there sat for the R.H.S. Parks Examination, securing a First Class Certificate, and, with it, immediate promotion. During this period, he became Secretary of the now defunct British Gardeners' Association, and gave lectures at its meetings; his lectures attracted attention and did much to secure him the appointment of Assistant Lecturer at the Horticultural Department of Reading University, and the charge of the fruit estate at Shinfield. Later, he became gardener to Lord Marcus Beresford, and early in 1914 he took charge of Lord Rothermere's garden. At the outbreak of war, he became responsible for supplies of vegetables and fruits to local and London military hospitals, adding two other gardens and, a stretch of agricultural land to Lord Rothermere's garden for this purpose. Not long afterwards, Mr. Hartless joined the Army, and on the conclusion of the armistice, gave horticultural lectures and demonstrations to the troops in France, many of the men being Canadians. On demobilisation, Major Harrison invited Mr. A. J. Hartless to return to King's Walden Bury to assist Mr. Hartless senior in bringing the gardens back to their former well-kept condition. This invitation was accepted, and in February, 1919, he commenced the work of reconditioning the famous rock garden, and by the following spring had raised no fewer than 20,000 plants for that purpose. Mr. Hartless senior retired in 1921, and since then his son has had entire charge, carrying out many alterations and improvements in Major Harrison's beautiful garden and arboretum. Mr. A. J. Hartless takes an active interest in the successful King's Walden Flower Show and the Hitchin Chrysanthemum Society, and for three years in succession he has won the Fruit Challenge Cup at Hitchin, with admirable collections of hardy and indoor fruits, besides many other awards.



MR. A. J. HARTLESS.

Diaries for 1929.—Among the diaries received by us with each New Year, none is more useful as a desk companion than the *Fruit, Flower and Vegetable Trades' Year Book and Diary*, published by the Lockwood Press, 1, Mitre Court, Fleet Street, price 2s. 4d. post free. The diary pages, interleaved with blotting paper, are ample for memorandum purposes, while the literary pages contain much useful information, including recent Acts of Parliament relating to State Insurance, the Marking of Fruits, and Shop Hours of Closing. There is a very informative article on "Mushroom Growing," by Mr. W. Dyke, and another, "The Manuring of Vegetable Crops," should prove helpful to the practical gardener. The publication contains much valuable statistical matter, and a diary of monthly operations in orchard, market garden and nursery. There is also much of interest to florists, the notes and illustrations dealing with the making of wreaths, etc., being especially valuable.—A very handy pocket diary, extremely well bound and of convenient dimensions, has been published by the Sundries Department of Messrs. Geo. Monro, Ltd., 4, Tavistock Street, Covent Garden, W.C.2. It is composed of two distinct and separately bound sections, the first, containing reference notes on cultivation, manuring, insect pests and fungus disease control, planting and other subjects, together with several useful tables, is held by an elastic band and may be removed if necessary. The diary portion is in two sections, one for ordinary memorandum purposes, and the other for monthly cash accounts.

"Ten Months Abroad."—Under this title, Mr. William Cuthbertson, V.M.H., has produced a small book of 187 pages, giving an account of his recent trip, with Mrs. Cuthbertson, round the world. It is intended for distribution among his friends and relatives only, and consequently has been written in an easy and charming style, with many personal touches, yet it is withal highly instructive, being the result of keen and shrewd observation concerning the individuals met, and the places and establishments visited, throughout the tour.

National Rose Society.—The fifty-second annual general meeting of the National Rose Society will be held at Caxton Hall, Victoria, on Wednesday, January 16, at 2.30 p.m. Consideration will be given to a proposed new rule in place of the present Rule No. 20; it is as follows:—All questions affecting membership or the conduct of any member of the Society shall be dealt with by the Council in its absolute discretion, and the Council may, by a majority of two-thirds of the members present and voting at a meeting convened by a notice stating that the removal of a member will be considered thereat, or at a meeting specially convened for the purpose, order the removal of the name of any person from the list of members, and thereupon such person shall cease to be entitled to any of the rights and privileges of membership of the Society.

American Investigation of Lily Pests and Diseases.—During the year 1928, an intensive study of the diseases and pests of Lilies was conducted through the medium of a Lily Disease Investigation Fellowship, organised through the co-operation of the Horticultural Society of New York, the Boyce Thompson Institute of Plant Research, the Cornell University, and the New York Botanic Garden. The Fellow for Research, Mr. Carl F. Gutterman, has presented a brief summary of the first year of this Fellowship, while a complete report of the year's work will appear in the *Year Book* of the Horticultural Society of New York. Mr. Gutterman states that most of the failures in growing Lilies are due to diseases and to attacks of insects, and not merely to factors of culture as is generally supposed. The mosaic disease, due to a contagious virus, is the most serious disease of Lilies; a diseased plant never recovers, and so long as it lives it is a source of contagion for healthy plants. Investigations indicate that the disease is distributed by insects and probably by aphids. During last winter, Mr. Gutterman spent some time in Bermuda, studying the "yellow flat" virus disease which has proved so destructive to Bermuda Easter Lilies. The botrytis blight, a serious fungus disease of various Lilies, is described in the report, and methods for controlling it are given, while several fungi responsible for the rot of Lily bulbs in storage and transit have also been determined, and experiments for their control are being conducted. It is also stated that the bulb mite causes very serious injuries to Lily bulbs, both under glass and in the open garden, in America. At present no efficient control for this insect is known, and the subject is to receive special attention in the future.

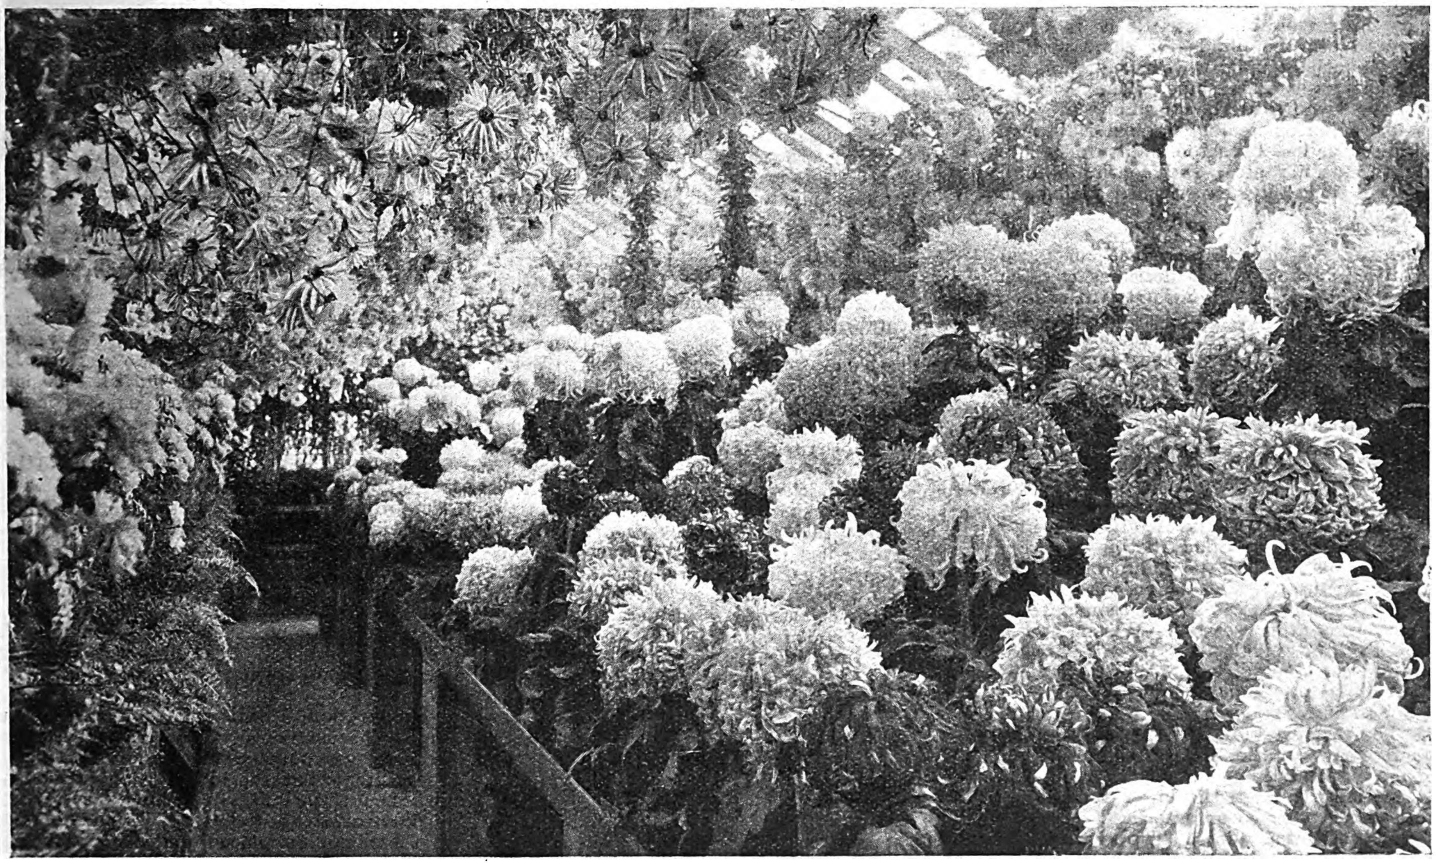


FIG. 9.—CHRYSANTHEMUMS AT DOWNHILLS PARK, TOTTENHAM.

The Royal Gardeners' Orphan Fund.—The annual meeting of subscribers to the Royal Gardeners' Orphan Fund will be held in the Lecture Room, at the R.H.S. Hall, Westminster, on Wednesday, February 13 next, at 3 p.m., when the Committee's Report for 1928 will be submitted, and the Officers for 1929, and the duly nominated orphan children, will be elected. All particulars concerning the Fund may be obtained from the Secretary, at 19, Bedford Chambers, Covent Garden, W.C.2.

Gift for Scientific Research at Cambridge.—We understand that the late Mr. John Humphrey Plummer, an estate-agent of Southport, who died a short time ago, left estate valued at £250,000, almost all of which has been bequeathed, in the form of a trust to be known as the John Humphrey Plummer Foundation, to Cambridge University. The bequest is intended for the endowment of two chairs at Cambridge for the promotion of modern scientific research.

American Iris Society.—During the past year, this Society has been actively engaged in further increasing the popularity of the Iris in America, chiefly through the medium of exhibition gardens, which are being established throughout the United States. A garden, containing one hundred varieties of Irises, has been laid out at the Normal School, Keene, N.H., while approximately one hundred varieties are being used at the Massachusetts Agricultural College; and one-hundred-and-twenty-five varieties are to be planted by the Haverhill Park Department next spring. Four hundred varieties of bearded Irises are being tried at the Harvard Botanic Gardens, Cambridge, Massachusetts, and the University of New Hampshire has received ninety varieties. Arrangements are also being made to establish exhibition gardens at the Maine, Vermont, Connecticut, and probably the Rhode Island, state colleges.

Chrysanthemums at Downhills Park, Tottenham.—The gardens at Downhills Park, Tottenham, are a great attraction during the summer months when the flower beds are particularly bright, but in the autumn Chrysanthemums take pride of place and attract thousands of people from far and near, who not only pay tribute to the cultural ability of Mr. E. Welfare, but also to the skill with which he arranges his flowers, especially in the festooning of the interior of the roofs of the greenhouses with Single varieties (Fig. 9). That these displays give much pleasure and satisfaction is proved by the fact of the public subscribing, through the medium of collecting boxes, over £100 in aid of local hospitals. The photograph from which our illustration is reproduced was taken by Mr. W. P. Lovelace, of Highgate, an amateur of no mean skill.

Appointments for the Ensuing Week.—Monday, January 14: East Anglian Institute of Agriculture lecture; Streatham Rose and Sweet Pea Society's lecture. Tuesday, January 15: Royal Horticultural Society's Committees meet; Winchester Horticultural Society meets; Croydon Gardeners' Society's annual meeting. Wednesday, January 16: National Rose Society's annual meeting; Buxton and District Chrysanthemum Society meets; Burton-on-Trent Chrysanthemum Society meets. Thursday, January 17: Ipswich Gardeners' Association meets; Gainsborough Chrysanthemum Society's annual meeting; Sundridge and Brasted Horticultural Society meets. Friday, January 18: Manchester and North of England Orchid Society meet; Dundee Horticultural Society meets.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Sequoia sempervirens and gigantea the same.*—I am well acquainted with every part of the country trod by Douglas. Douglas's journeys seldom exceeded thirty miles from the coast, and if he visited the grounds in latitude 38° 15′ N., the only Coniferous tree he could have seen for twenty miles from the coast was Taxodium sempervirens, some scattered specimens of Abies Douglasi and Pinus Edgariana. From twenty miles from the coast eastward to an elevation of one thousand feet on the Sierra Nevada, scarcely a Coniferous tree of any kind exists. Hartweg travelled over Douglas's tract from south to north, and never saw Wellingtonia, from which I venture to say that that plant was never found except in the locality stated in the *Chronicle*, which is more than 160 miles away from the coast, and fully 120 miles from Douglas's track. The tree alluded to by Douglas is unquestionably the Taxodium sempervirens of Lambert, or Sequoia of Endlicher, which he must have seen in great abundance, both on the mountains of Santa Cruz and of Santa Lucia. From my own knowledge of this tree, it abounds along the coast from latitude 35° 30′ to Humboldt in latitude 41° N., which may be its northern limit. It occupies the deep, gloomy ravines of the western slopes of the mountains, rarely on the east sides, and seldom beyond the elevation of 2,000 feet above the level of the sea. Taxodium sempervirens is the largest tree I saw in California, before the discovery of Wellingtonia; it presents to the eye all the beauty and grandeur that Douglas has described. I have often seen trees three hundred feet high, and from ten feet to fifteen feet in diameter. *W. Lobb.* [It will be seen from this statement that we were right in regarding Wellingtonia as different from the plant described by Douglas. Sequoia gigantea must now be erased from catalogues, it being a nonentity.] *Gard. Chron., January* 14, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE
Manchester.

Preparations for the Coming Season.—A good stock of potting materials, *i.e.*, pots, fibre, loam, charcoal, sand, etc., should be obtained, the fibre and loam prepared, and crocks crushed in readiness for the busy potting season now approaching. A supply of fresh Sphagnum-moss should be secured during open weather; this is very difficult to obtain during severe frosty weather, and when supplies are held up it often means delay in necessary repotting. Any arrears in washing down and cleansing the houses should be dealt with so soon as possible, also any necessary repairs or additions to the blinds should be attended to now, so that they may be ready for use in the early spring; in favourable districts it is often necessary to use the blinds for short periods early next month over plants with tender foliage, during bright spells of sunshine, when very cold winds prevent much air being admitted. The foliage of Odontoglossums, in particular, is often injured or lost by a too sudden exposure to bright sunshine after the continued dull weather and short days experienced during the winter months.

Temperatures.—The maintenance of even temperatures in the different divisions is often very difficult at this season, owing to the sudden changes of the weather, and the usually very cold winds experienced during the early part of the year. Fluctuations of the temperatures should be avoided so much as possible by careful heating and ventilation; both are necessary in all divisions now, but excessive use of either should be avoided, as more damping down is required to counteract the dryness in the air and the plants may thereby be started prematurely into growth, while cold draughts are injurious. No plants should be hurried into growth at this season; much better flowering growths are obtained as the hours of sunlight increase and more genial conditions prevail. As a general guide, the following temperatures are suitable at this season:—Warm house, day, 65° to 70°; night, 60° to 65°; intermediate house, day, 60° to 65°; night, 55° to 60°; and cool house, day, 55° to 60°; night, 50° to 55°. The maximum temperature should be reached about noon and the minimum early in the morning. Fresh air should be admitted on all favourable occasions, especially through the lower ventilators, where the air is warmed on entering by contact with the hot-water pipes. Top ventilation should be given every day during suitable weather, if only for a short period, so as to keep the atmosphere sweet.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN,
Brocket Hall, Hertfordshire.

Chrysanthemums.—Where large blooms of Chrysanthemums are required, rooted cuttings of such varieties as Majestic, W. Rigby, Mrs. G. Drabble and Queen Mary should now be ready for transferring singly into sixty-sized pots. These varieties require a long season of growth to produce the best results, while the propagation of most of the others is best delayed until now. After being potted, they should be stood on a shelf near the roof-glass. The soil for this potting may consist of three parts loam and one part leaf-mould, with a little bone-meal and sand added. This mixture should be prepared several days before it is required for use and placed in the house so that it is warmed to the house temperature. Cuttings of other Japanese varieties, also of Single and Decorative sorts, may now be inserted in sandy soil and stood in a propagating frame, where they should root readily in a temperature of about 50°. It is a great mistake to attempt to root Chrysanthemum cuttings in a high temperature, as this usually results in thin, spindly growth. Some growers place the cuttings singly in thumb pots, but I see no necessity for this practice; several may be placed in each pot, provided they are not allowed to remain in the receptacles until the roots become entangled. Remove the lights each morning to allow the condensed moisture to escape. After sufficient stock has been secured, many of the old stools may be dispensed with, retaining only sufficient to secure late cuttings in April to produce small plants for growing in six-inch pots for decorative purposes. It is surprising what large blooms can be obtained from plants in pots of this size, if they are grown on a single stem; personally, I consider this the best method of cultivating Chrysanthemums for grouping purposes.

Carnations.—The top ventilators of the house in which Carnations are in bloom should be open night and day, and unless the weather conditions become too severe, they should never be closed tightly. A night temperature of 50° is suitable for plants in flower, but on mild nights this temperature may be exceeded by several degrees, to the benefit of the plants. On the other hand, allow the temperature to fall a few degrees on frosty nights rather than create an arid atmosphere, as this would result in weakened growth. Concentrated manures should be used sparingly just now, but the amount may be increased towards the end of the present month.

Carnation Pests.—Red spider, rust and thrips are probably the worst enemies of the Carnation. The former may be kept in check by spraying the plants with salt and water, using two ounces of salt to the gallon of soft water. This spray will also help to keep rust in check. Volck, used according to directions, proves a very efficient spray for this pest. This will be found to take the "bloom" off the foliage, but it returns in a very short time. Rust may be treated with a copper compound that can be obtained from most sundriesmen. Thrips are sometimes a source of trouble, and unless checked in the early stages, the flowers will be marked badly. This pest has a great liking for the dark-coloured varieties. Frequent fumigating with nicotine should keep thrips in check, but when attacks are severe it may be necessary to spray the buds frequently in their early stages with pure nicotine (one ounce to two gallons of water), but buds showing colour should not be sprayed. Vapourising the house with flowers of sulphur after all the open flowers have been cut, is also a good method of dealing with this pest.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P.,
Ford Manor, Lingfield, Surrey.

Pot Figs.—The earliest house containing Fig trees in pots will have been closed last month and growth should soon be moving. If fermenting material of litter and leaves is used, this will be found of great assistance, and may be added to with advantage to keep up a steady temperature, and also to maintain suitable atmospheric conditions. A steady bottom heat of 75° to 80°, with a night temperature of 58° to 60° on mild nights, and 70° to 75° by day, in favourable weather, together with light syringings and damping down, and a little air admitted on bright mornings, should be found suitable for trees started last month. The second house,—in many cases the first house—, should now be closed; if pot trees are used, the treatment advised above, with a night temperature of 48° to 50°, rising 5° to 10° higher on bright days, will be suitable. Syringe the trees and damp the houses carefully according to the outside atmospheric conditions, so that the trees may be dry before nightfall. Avoid any hard forcing at this stage in cold weather; rather let the heat decline a few degrees. Close permanent Fig houses and treat them in a similar manner, water the borders with tepid water at least twice to bring them into a moist growing condition, and keep a sharp look-out for mealy bug at this stage.

Early Vines.—Close the permanent vinery now if ripe Grapes are required at the end of May or beginning of June. Water the border once or twice with tepid water to restore it to a moist condition. Syringe the vines and damp the house daily in bright weather, and keep the house closed for a fortnight or three weeks; the night temperature should be about 48° during that period.

Vine Propagation.—If the planting of new vineries or the renewal of old ones is contemplated, a sufficient number of eyes should be inserted during the present month in small pots or pieces of turf and placed in steady bottom heat. If a suitable house or pit is not available, collect the growths and defer the starting of the eyes until next month, as when the days lengthen growth will be rapid and make good any apparent delay at the present time.

General Work.—Continue to push forward the work of pruning, top-dressing, and washing and cleansing the houses and trees. All late late houses should be cleared of Chrysanthemums or other tender plants so soon as possible, to give them a few weeks' rest before using them again. The weather of late has been so mild that all fruit trees under glass have not gone to rest so early as they should have done.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens,
Wisley, Surrey.

Planting.—The open weather experienced during autumn favoured out-door planting, but where arrears are still to be made up, it is advisable to defer the work until the beginning of February, when more genial conditions may be expected. The preparation of the ground should be pushed forward on every favourable opportunity. Where time and labour permit, all beds and borders should be trenched. The after results will justify the extra time spent in the initial preparation of the ground. Where planting is to take place in grassland, the holes may be opened and the soil left exposed to the weather for a few weeks, but under this system it is usually found best to open the holes as planting is proceeding. By doing so the chance of the soil exposed becoming sodden and unfit for planting is obviated.

Preparation of Soils.—It is wise to have a supply of the various soils required brought under cover so that they may be available no matter what the outside conditions may be. Loam, leaf-soil, sand, and a small quantity of peat will be the principal ingredients needed. If these can be placed under cover now, no difficulty should be experienced in having them in good condition as required during the next two months. Next to the supply of soil, the seed-boxes should be looked over and those requiring repair attended to. Seed pans and pots should be washed in readiness for the busy season.

Seed Sowing.—Seeds of a few subjects that require a long season to produce the best results will require to be sown now. This applies especially to the more northern districts. East Lothian Stocks, if sown now, and afterwards grown on in a cool house, exposed to plenty of light, make valuable bedding plants which give a long season of bloom. Probably the best time to sow these to get the best results is in early autumn, but for those who have omitted to do so, now is a favourable time. Antirrhinums, if not sown during autumn, should be sown now and grown on under cool conditions. These provide a wonderful range of colours, and are valuable where large quantities of bedding plants are required at small cost. The much despised Verbena venosa is easily raised from seeds, but requires a long season of growth to ensure the best results. Many gardeners seem rather afraid of the colour of this subject in the flower garden, yet it makes a very pleasing bed if used in conjunction with a grey-foliaged plant, such as Centaurea Cineraria, as an edging, and either Diplacus (Mimulus) glutinosus or Calceolaria amplexicaulis as dot plants. Sow sufficient seeds of Centaurea Cineraria and Cineraria maritima to ensure a plentiful supply of grey-leaved plants for the summer bedding schemes. These silvery-grey-leaved subjects give a quiet and restful effect to the flower garden and should be used more freely.

Fuchsias, Heliotropes, etc.—Where large numbers are required, stock plants of these and other subjects should be placed in a warm pit to provide sufficient growths for propagation purposes next month.

Herbaceous Borders.—Where it was not possible to complete the lifting and transplanting of herbaceous plants, as anticipated during autumn, no opportunity during open weather should be missed for completing the trenching of the borders in readiness for planting during February and March. To ensure the plants doing well, the soil should be trenched at least two spits deep; the subsoil should be broken up, and should have added to it any decomposed vegetable matter available. If the soil is heavy, mix plenty of grit, burnt refuse, decayed leaves and horse manure with it; if light and sandy, cow and pig manure and decayed turfy loam, mixed freely with it, should give the best results. It is not advisable to do much planting this month, except on warm, sandy soils, but every endeavour should be made to have everything in readiness for the time when planting may be carried out with freedom.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Rhubarb.—Good stools of Rhubarb should be lifted and placed in the forcing house; plenty of leaves should be pressed well around the roots, and an even temperature should be maintained in the structure. Seeds of Rhubarb may be sown in boxes, to raise plants for making new beds. Prick the seedlings off into three-inch pots or into boxes when they are large enough to handle, using a compost of good loam and a little sand. Where new beds of Rhubarb are required, the ground should be trenched and plenty of manure and old leaves worked into it.

Asparagus.—When forcing Asparagus, it is important that four-year-old roots are available for this purpose. Deep frames, with plenty of horse manure placed in the bottom and well trodden down, then covered with four inches of soil, should be prepared. Pack the roots closely together, then cover them lightly with soil. Keep plenty of mats handy for covering in case of frost.

French Beans.—For growing early Dwarf Beans under glass, eight- or nine-inch pots may be prepared, placing clean crocks in the bottom and covering them with rough material for drainage. Fill the pots with good fibrous loam to three-quarters their depth, and place them in a warm house, and give the soil a thorough soaking with water to settle it. The following day, sow five to six seeds in each pot.

Broad Beans.—Broad Beans that were sown in the autumn of 1928 should have a mulching of short litter placed between the rows to provide protection from frosts. Another sowing may be made on a border facing south. The ground for this crop should have plenty of manure worked into it and should be deeply dug or trenched.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

North Walls.—Many gardeners have an extensive area of wall surface with a northern aspect, and the profitable employment of such wall space for fruit trees is, in many cases, not taken full advantage of. The Morello Cherry is employed universally for such an aspect and, on occasions, we find use made of the stewing varieties of Pears, such as Vicar of Winkfield, Catillac and Uvedale's St. Germain. It is not general, however, to find the Sweet Cherry in such a position; yet there are several excellent dessert varieties which not only thrive but bear an abundance of fruits when given a northern aspect, thereby extending the season of this most useful dessert fruit. The soil in which the trees are to be planted should, of course, be of the best, to compensate, so far as possible, the handicap incurred by the absence of sunshine to warm the air and soil. The few essentials are ample drainage, and the addition of good turfy loam to improve the staple soil, together with some lime rubble, and half-inch bones. It is of great importance, too, that the trees should be planted so shallowly as possible. Keep the roots near the surface, where the soil is warmer, and apply a mulch during the summer months. The varieties of Sweet Cherries that succeed admirably under such conditions are Early Rivers', Elton, Governor Wood, Napoleon, Noble, and Florence. This last variety is one of the latest to ripen its fruits. and is therefore particularly useful in extending the Cherry season.

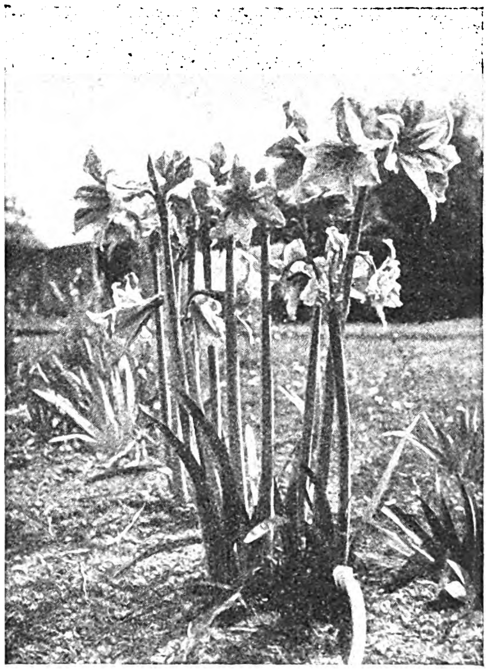

FIG. 10.—HIPPEASTRUMS IN KENYA COLONY.
(see p. 27.)

Black Currants.—Where the planting of Black Currants has been deferred, the earliest opportunity should be taken to complete this work. The soil, however, should be in a dry or crumbly condition to perform the work satisfactorily. It is becoming fairly general among commercial growers to plant the one- or two-year-old bushes in groups of three instead of singly as was, at one time, the custom. They should be planted a foot apart, and six feet should be allowed between the centre of one group and the centre of the next, and the same distance between row and row, the object being to obtain the utmost value from the space while the bushes are young and healthy. It is economical to plant one- or at most, two-year-old bushes, for it is very important that, immediately the planting is completed, the young bushes should be cut down almost to the ground level. This will induce each plant to produce three or more strong shoots in the coming season, which will bear fruits next year. For home use, or for local sales, there is no better variety than Boskoop Giant. The berries are large and sweet, and ripen almost a fortnight before any other. The varieties Baldwin and Goliath are both very heavy croppers and may be termed mid-season. Daniels' September should prove a useful late variety to those who are obliged to supply late fruits for stewing.

Established Black Currant Plantations.—The Black Currant is of such a fibrous-rooting nature that no attempt should be made to dig near the bushes. I am firmly convinced that the bulk of "reversion" is brought about by thoughtless mutilation of the roots. Draw back the surface soil from about the base of each bush, mulch with well-rotted farmyard manure to the full spread of the roots and, as you "point" between the rows, throw a forkful or two of clean soil on the manure to keep it in position. Where farmyard manure is not obtainable, a mixture of three parts bone-meal and one of sulphate of potash, applied at the rate of two or three handfuls to the bush, should form a useful substitute.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Early Vegetables.—Where frames or pits are available for growing early vegetables, a good supply of hot-bed material should be prepared. Leaves and horse manure in equal proportions, or even leaves alone, if turned once or twice, should be in good condition for using when the time arrives.

Gooseberries.—Where birds are not troublesome in picking the buds off Gooseberry bushes, these should be pruned so soon as time allows. Depend mostly on the young wood for the production of fruits, cutting out all growths crossing or growing towards the centre of the bushes, so that the branches left radiate from the centre. Stray suckers or basal shoots should be removed with the heel intact and not cut back. When rearing young bushes, the leaders should be cut back to a bud pointing outwards, but when the bushes have reached full size little or no cutting back is necessary.

Red Currants.—All the lateral growths on Red Currant bushes should be spurred back to a few buds, leaving the leaders longer if necessary for extension purposes.

Black Currants.—Remove part of the old growth completely to admit sun and air to the centre of the bushes and lay in a succession of strong, young shoots from the base. By keeping the bushes in vigorous growth, big bud, and also reversion, are not so likely to affect them. If any evidence of big bud is present, remove the affected buds or, if possible, the shoot, and burn them at once. Then, in March and April, spray the bushes with a one per cent. solution of lime sulphur at intervals of ten days or so. Although not a cure, this retards the spread of the pest, and if the bushes are clean, may act as a preventive. The small-fruit quarters should not be dug, as surface rooting should be encouraged. A good top-dressing of fowl or other manure is beneficial.

Raspberries.—These will, of course, have received treatment some time ago, but if the canes overtop the wires or other supports, do not cut them back until March.

Hippeastrums.—Where a stock of these subjects exists, and the bulbs are in a well-ripened state, they should now be ready for starting, and may be brought on in batches as required. If the roots are in good condition it is a mistake to repot them; merely soak them in water and, after allowing the surplus water to drain off for a day or two, remove an inch or so of the surface soil and replace it with a mixture of equal parts of good loam, leaf-mould and sand. Plunge them in a mild hot-bed. when the flower spikes should soon make their appearance. If repotting is necessary, use a similar compost to that advised for top-dressing; a small quantity of ground bones may be added, but no animal manure. So soon as the flowers are over feed the plants with diluted liquid manure once or twice a week until growth is complete, when they should be gradually dried off, withholding water entirely by September.

FLOWER GARDEN.

SWEET PEAS.

One need not be an optimist to note continuity in the progress of the Sweet Pea; this is perhaps best substantiated by the present unique position of the National Sweet Pea Society. This concurrence of public favour is not without vindication, when one considers the flower of to-day in relation to its ancestors, particularly in form, size of flower, length of stem, the various and most delightful colours, and its sweet perfume, which, in spite of it having lost a small percentage at the expense of the other qualities, is sufficient to insure its favour as an indispensable florists' subject.

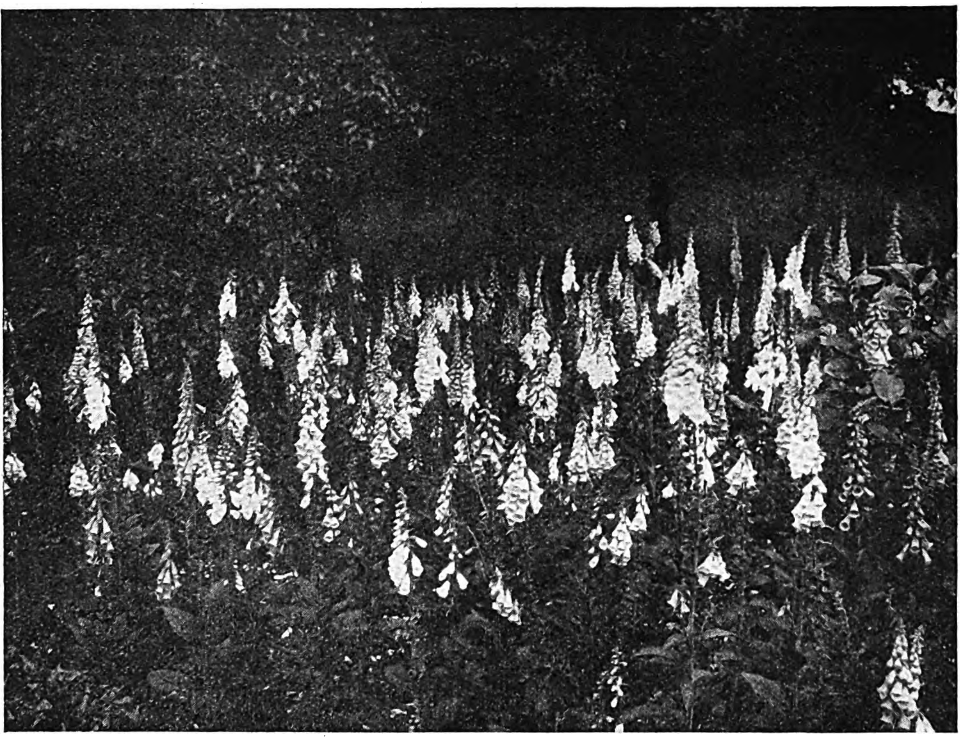

FIG. 11.—FOXGLOVES ON THE EDGE OF WOODLAND AT KEW.

The question of autumn or spring sowing of Sweet Pea seeds has always been a subject of controversy, but it really depends on the purpose for which the flowers are required, and the particular situation and locality in which the grower is placed. While autumn sowing is given preference by many, chiefly in view of producing blooms for exhibition, those who have deferred sowing until spring need have no apprehension, as excellent results may be obtained from seeds sown about the third week in January. A suitable compost for this purpose consists of three parts sifted loam and one part leaf-soil, with sufficient sand added to render it porous. The seeds are best sown in sixty-sized pots, as they may then be transferred to their flowering quarters without check at planting time; incidentally, the number of seeds to be sown in each pot should be equal to requirements in regard to purpose and space, provision being made for failures. Upon the completion of sowing sufficient water should be given to soften the seeds and encourage germination. The previous soaking of Sweet Pea seeds is not to be recommended, as, in consequence of this unnatural stimulation, subsequent vitality may be impaired. The practice of chipping seeds prior to sowing is not to be recommended; it is better to wait until about ten days have elapsed from the time of sowing, when, if any seeds are still found to be hard, they may then be chipped, and replaced in fresh soil.

Difficulty is often experienced in germinating white-seeded varieties, such as Matchless and Avalanche, owing to the seed coat being thin, and therefore very absorbent. This may, to some extent, be overcome by filling the pots to two-thirds their depth, and covering the surface with sand, into which, after it has been thoroughly watered, the seeds may be lightly pressed to half their diameter.

Cover the pots with sheet glass and paper, and when germination has taken place cover the seeds lightly with a sandy mixture. Although germination is conveniently accelerated by a temperature of 50 to 55°, particularly at this time of the year, the Sweet Pea is, nevertheless, a hardy annual, and to ensure success, it must be treated as such. The seedlings should be removed to cooler quarters and subsequently to cold frames so soon as possible, and finally hardened in readiness for planting.

The stopping of the plant has the effect of promoting strong basal growths. This should be done at the second leaf, and it is of importance that the prospective growths be visible, accompanied by good root action, before the operation is performed.

Among the varieties of Sweet Peas which should suffice to meet the needs of all classes of growers are Magnet, Olympia, Mrs. A. Searles, Gleneagles, Powerscourt, Grenadier, Jack Hobbs, Daffodil, Avalanche, Pinkie, Sybil Henshaw, Warrior, Charming, Sunkist, What Joy, Youth, Lilac Queen, Model, Bluebird, Chieftain, Huntsman, Hero, Delightful and Royal Sovereign.

Sweet Peas that were sown in October and are being grown for exhibition purposes should be potted singly into sixty-sized pots towards the end of January, returned to cold frames and kept close for a few days, after which, so soon as practicable, the lights should be removed altogether. *Thomas Baines.*

WILD GARDEN.

SENECIO JAPONICUS.

Senecio japonicus (syn. Erythrochaete palmatifida) is a stately plant, eminently useful in the wild garden or by the side of a pond or stream. It was introduced from Japan in 1866, and received a considerable amount of attention for some years after its introduction, but latterly has been planted less frequently in gardens. It is occasionally employed at the back of large borders, but there it does not always receive the amount of moisture it requires to enable it to reveal its true character.

S. japonicus is a true hardy perennial, and may be raised from seeds or increased by division. In one book of reference in my possession it is stated to attain only three feet in height, but this is an error, as it should grow to at least five feet high, and I have seen it nearly seven. It has handsome leaves which are about one foot in length, and usually divided into nine divisions. The flowers are of bright orange, and are borne on slightly branched stems during summer; they continue to open over a long period. As already indicated, S. japonicus requires a moist soil to enable it to show its true effect, and although planting it in a rich, stiff loam will, to some degree, compensate for lack of moisture, it will not do this satisfactorily, and the pond side or margin of a stream should fulfil its requirements much better than the border. *S. Arnott.*

WOODLAND GARDEN.

FOXGLOVES.

It is surprising that the Foxglove, naturally a plant for semi-shaded places and so well adapted to naturalising in the woodland or wild garden, is not used more extensively for this purpose, for the tall, stately spikes of richly-coloured flowers might be employed to brighten many a drab and uninteresting spot. The illustration (Fig. 11) depicts a group of them in just such a position at Kew, and the effect so produced was charming.

But it is not necessary that they should be confined to set beds; groups may be planted here and there among shrubs of only moderate stature, in the same way as Lilies are often employed, and having once been introduced to the woodland, they will firmly establish themselves, scattering their seeds and so providing a natural succession. During recent years the Foxglove—Digitalis purpurea—a familiar plant in woodland and hedgerow in this country, has been much improved by plant specialists, so that now several fine strains are available, the most striking that has come under my notice recently being that secured by W. B. Cranfield, Esq., Enfield, a strain typified by giant spikes of large, richly and delicately shaded blooms.

In passing, mention may also be made of Digitalis ambigua, of more lowly stature than the better-known native Foxglove, but, nevertheless, very charming when naturalised in the wild garden or in open woodland, in portions not too heavily shaded. The flowers of this species, from Switzerland, are pale yellow, and like its more stately congener, it produces an abundance of seeds with unfailing regularity, and has the same trait of being able to care for itself having once been introduced. Attempts have, I think, been made to cross this species with D. purpurea, but I do not think much success has yet been obtained in this direction. *F.*

THE GREENHOUSE ON NEW YEAR'S DAY.

The flower shops and market lists of plants in pots offer little beyond Azaleas, Ericas, Cyclamen, Primulas and foliage plants at this time of year. Yet visits to Kew and the diligent study of the Assistant Curator's recent notes on "Plants under Glass" in *The Gardeners' Chronicle* will suggest many others. Indeed, it is to Mr. Coutts' skill in finding good winter-flowering subjects that we at Burford owe most of our flowering plants at Christmas, all of which are grown in five-inch to eight-inch pots.

Buddleia asiatica bears sprays of white flowers with the fragrance of Freesias. It is a good house plant, as is Sparmannia africana, which is grown as a standard and carries its large clusters of white flowers well above the Plane-like foliage. The flowers are very interesting, as the red and golden stamens are sensitive, and when touched open fanwise; cuttings produce standards in a year. Reinwardtia trigyna and R. tetragyna are two beautiful plants with pale and deep yellow flowers, respectively, which resemble, but are double the size of, those of Linum arboreum.

Hibbertia volubilis is a noble plant with large glossy leaves and large yellow flowers, like St. John's Wort; the seeds are bright scarlet. H. montana is a neat little shrub and H. radicans is a beautiful climber with reddish stems and leaves; the flowers of both are bright yellow and freely produced. Libonia floribunda is a very old garden plant bearing tubular, scarlet flowers with orange tips, while Strobilanthes isophylla has beautiful, dark-green, pointed leaves and lilac, Pentstemon-like flowers—both are good house plants. Two pretty blue Nettles are Coleus floribundus, an east African plant with cobalt flowers, and Plectranthus chiradgulensis, with turquoise flowers: unfortunately, the flowers are rather sparse on both plants. The Correas are neat in habit and last well in a room; C. speciosa var. Harrissii is floriferous and carries deep pink flowers, while C. cardinalis, usually grafted on C. speciosa has scarlet flowers but is not so good a grower. Eranthemum pulchellum, which used to be so well shown at the R.H.S. meetings by the late Duchess of Wellington, has beautiful blue flowers, unfortunately fugacious. There is a considerable choice of Jacobinias. J. coccinea is scarlet and J. chrysostephana orange, both brilliant in colouring.

Of greenhouse plants, the Acacias take a lot of beating. They may be grown and flowered in thumb pots, and when planted out they make trees. The first to flower here is A. platyptera, which, with its broad phyllodes, is curious, rather than attractive. An elegant plant known here as A. (Albizzia) lophantha Neumannii, has sulphur-yellow or sulphur-green flowers and pinnate leaves; A. linearis is a very elegant plant with light feathery foliage; A. armata, of which the type has long leaves, while there is a short-leaved variety (A. a. brevifolia), a first-class plant with neat habit and masses of flowers; A. Drummondi has small Vetch-like leaves, and carries its flowers on spikes—where it does well it is one of the best of the Acacias; A. pulchella, a thorny, tangled plant, with single balls of flowers, is very pretty; A. hastulata is the latest to flower and is well worth growing.

Two uncommon foliage plants may be mentioned, Exoecaria bicolor, a small shrub bearing dark green leaves with brilliant crimson undersides, and Cyanara aurantiaca, a Coleus-like plant, the upper surface of the leaves being covered with deep violet hairs.

In conclusion, one berried plant may be mentioned, Damnacanthus indicus, which resembles in growth a dwarfed shrub, with tiny, Holly-like leaves, and bright scarlet berries; the creamy-white and green flowers are comparatively large; and one bulbous plant, Lachenalia Boundii, which produces immense spikes of brick-red flowers a month before other Lachenalias; six bulbs planted last autumn are already fifteen, with fifteen spikes. *William Lawrence, Burford.*

INDOOR PLANTS.

HIPPEASTRUM ADVENUM MAJOR.

The recent illustration and description of the above subject, which appeared in the issue of *The Gardeners' Chronicle* for October 27, 1928, solved a puzzle that I had been unable to elucidate for the past year. Prompted by a reference to Habranthus pratense I had made in a trade journal, E. O. Orpet, Superintendent of Parks at Santa Barbara, California, wrote me to the effect that he believed I had named for him a bulb he had been growing for years under the name of the Blood Lily. This bulb he stated, is grown extensively on the coast, as it is a prolific multiplier, rivalling some of the Daffodils. In all the years he had grown it, despite his excellent knowledge of botanical subjects—Mr. Orpet was at one time a noted gardener and Orchid grower in New Jersey—he had never been able to identify this red-flowered bulb, obviously related to the Amaryllis.

In due course (late summer), he sent me some bulbs, some of which I potted, the rest being planted out-of-doors. All flowered late last fall, when I at once realised they were only distantly related to Habranthus pratense. The bulbs out-of-doors did not survive the winter, while those in pots, having to be kept in an ordinary room, developed rather weakly foliage and consequently failed to flower this fall. In California the plants were flowering freely in mid-November.

I have no doubt as to the identity of this bulb, as Mr. Worsley's description and illustration, referred to above, so accurately fit. Johnson's *Gardeners' Dictionary* and Bailey's *Standard Cyclopedia of Horticulture* afforded no means of identification, the references being so brief.

I would not state that Hippeastrum advenum major is a brilliant subject, but it is undoubtedly worth more attention than it has apparently received. *T. A. Weston, New Jersey.*

HIPPEASTRUMS AT KENYA.

The beautiful Hippeastrums (Amaryllis) cultivated with such care and success under glass in England, are, writes Mr. W. F. Glencairn Campbell, grown out-of-doors (Fig. 10, p. 25) in Kenya Colony where they make a fine display and grow as freely and flower as finely as any wild flower. The illustration certainly suggests that Hippeastrums find themselves very much at home in Kenya Colony.

BERTOLONIAS.

These elegant plants, their beautiful leaves almost rivalling those of Anaectochilus, require a warm, moist atmosphere with shade from strong sunshine; they are best grown in comparatively shallow pans, well-drained and filled with a mixture of fibrous peat or finely-shredded Osmunda fibre, Sphagnum-moss, silver sand and crushed crocks. During the growing season a night temperature of 60° to 65° should meet their requirements, rising in the day time proportionate to the prevailing climatic conditions; as the plants are of procumbent and somewhat spreading habit, their receptacles may be shallow, but of sufficient diameter to allow for the plant's reasonable increase. Several small pans containing plants, plunged in a large pan of chopped Sphagnum-moss and sand, is a convenient method of growing them, and the treatment is, apparently, suitable to Bertolonias. Cuttings afford a ready means of increase.

Desirable species are B. maculata, Brazil, 1850, figured in *Bot. Mag.*, t. 4551; B. pubescens, from Ecuador; B. marmorata, Brazil, 1858; B. guttata, referred to Gravesia, from tropical America; B. Houtteana, in all probability of garden origin; B. margaritacea, from Brazil; B. primulaeflora, from Ecuador, and B. superbissima, a garden hybrid.

These interesting and elegant little plants commemorate A. Bertoloni, an Italian botanist.

Light fumigation will effectually check the depredations of aphides, which sometimes attack these plants. *R. A.*

ACACIA VERTICILLATA.

This is a dense-growing Wattle of considerable beauty for the cold greenhouse or for growing out-of-doors in really warm, sheltered gardens. Where it is at home, it will reach a height of eight feet or more in the open. The fluffy heads of sweetly-scented blossoms are freely produced amid the Conifer-like leafage. As with the majority of Acacias, a mixture of loam and peat gives the best results. In normal seasons some flowers will begin to open in the latter part of February, continuing until mid-April or thereabouts.

Few subjects are more satisfactory than Acacia verticillata for planting out in a border of a large conservatory, while in well-protected gardens, where hard frosts seldom occur, this Wattle might well be given a trial in the open border, against a wall, with every hope of success. *C. Turner.*

WINTER-FLOWERING ANNUALS IN AMERICA.

An important part of the work of every American gardener who has greenhouses in his charge is the growing of various annuals to keep up a supply of cut flowers during the fall, winter, and spring months, and, indeed, in some establishments they are also grown under glass during the summer to augment the supply from the open gardens.

Such subjects as Antirrhinums, Stocks, Mignonette, Calendulas, Candytufts, Trachymene coerulea, Larkspurs, Gypsophila elegans, Hunnemannia fumariaefolia and others of like nature, are cultivated to an extent which would surprise the British gardener, and the quality of the crops so produced far exceeds that of similar subjects as grown in Britain. It is largely the intensity of the winter light which makes possible and profitable the intensive cultivation of these annuals. Disbudded Calendulas, on stout stems from eighteen inches to two feet in length, look cheery and possess a very decided decorative value in midwinter. Stout spikes of Antirrhinums, three or four feet in length and in many delicate shades, are always welcome and useful, while Mignonette well-grown and disbudded, takes on a new aspect, and is hardly recognisable as the same subject which is grown out-of-doors in Britain.

Of course, the houses are designed specially to accommodate these crops, which are planted in beds either on the ground level or on raised benches, provided with suitable soil. The latter method appears to give the best results with most subjects (Sweet Peas being a notable exception), and this is especially so with those which are to bloom during November, December and January. Houses of light construction are naturally favoured, and some of the best greenhouse builders use steel for the framework, even the sills being made of this material; and the glass supports consist of a wooden core with a steel backing to give the maximum strength with the minimum obstruction of light. Houses built in this way are glazed with glass cut to a twenty-four by twenty-five-inch size. The benches are made of a kind of slate or soapstone, with tile bottoms, although most commercial growers, as well as many private places, use concrete or Cypress wood for this purpose. They are from five-and-a-half inches to seven inches in depth inside.

When preparing the benches it is usual to place a layer of well-rotted manure on the bottom and then to fill almost to the top with a good rich compost, which is pressed quite firm. The young plants are then planted from two-and-a-half-inch pots at a distance appropriate to their anticipated growth. Calendulas do best when allowed twelve inches each way, but they are ofttimes only given ten inches; Antirrhinums require at least ten inches each way. After planting, watering must be attended to periodically and the surface of the beds kept lightly cultivated. Antirrhinums, Mignonette, Stocks and Calendulas are disbudded and suitable supports furnished as they become necessary. Feeding with liquid manure and other stimulants requires attention as growth demands.

The plants are raised from seeds sown either directly into the small pots, or in flats, to be transplanted later. The former method is preferable for Lupins. Antirrhinums are sometimes propagated by means of cuttings, but I find that seedlings give the best results, although occasionally colour variations appear. Stopping is necessary to secure a desirable branched growth with Antirrhinums and Mignonette, but most of the other subjects may be allowed to branch naturally.

The majority of these annuals are seldom troubled with diseases or pests, except possibly aphis, which is easily kept in check, but rust is much feared on Antirrhinums, and for this reason extreme care is necessary not to allow moisture on the foliage, and to provide adequate ventilation. A species of black root-rot sometimes causes loss among the Larkspurs. *T. H. Everett, New York, U.S.A.*

CRAWFURDIA TRINERVIS.

Crawfurdia trinervis, which the Japanese call Tsuru rindo (Climbing Gentian), is a plant worthy to be added to the collection grown by Gentian lovers. It inhabits semi-shady woodland, where it climbs over the shrubs or creeps on the ground, provided the soil is heavy and fertile. In its native habitat, the plants growing in the sunny portion are poor compared with those in semi-shade, while the best specimens in my garden are those growing in a sunny spot.

The leaves are dark green, opposite, entire, ovate-lanceolate, and pointed at the tip; the leaves on the main stem are four inches in length, while those on the lateral shoots are smaller by one-third or more. The Gentian-like, pale, reddish-purple flowers open in the late summer, and are followed by the bright, purplish-scarlet fruits which appear before the corolla withers, and make the plant very attractive. After experiencing several frosts, the fruits become much brighter in colour and are retained far into the winter. Crawfurdia trinervis (Fig. 12), is not tidy in habit, but is easily managed in the shrubbery or edge of a woodland, because it is not vigorous in growth. Callicarpa mollis, a deciduous shrub bearing lilac-violet fruits in our vicinity, is sometimes used as a support for the Crawfurdia, and the association is a finely contrasting one.

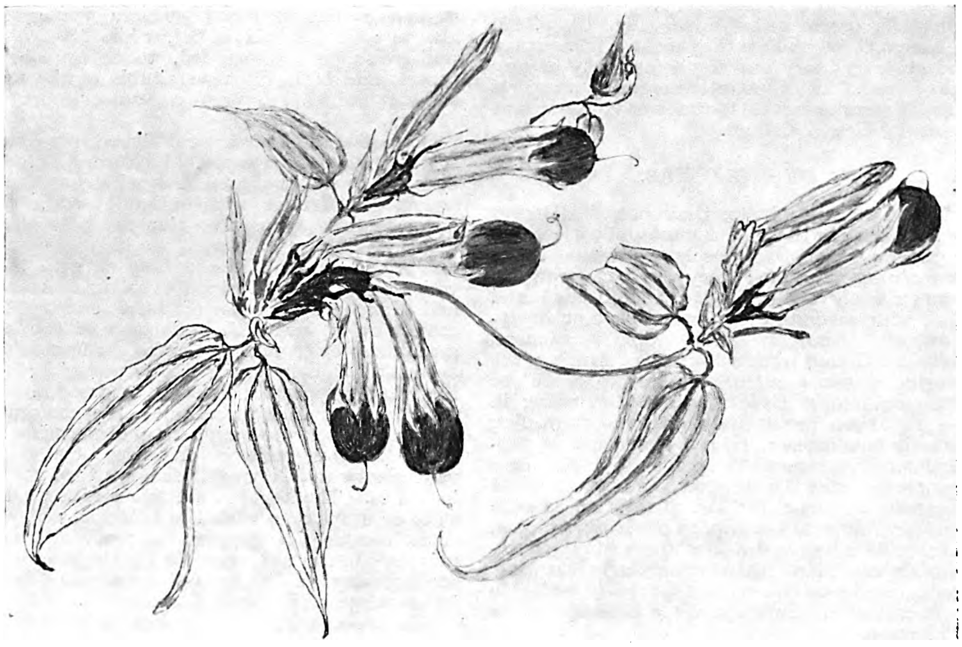

FIG. 12.—CRAWFURDIA TRINERVIS.

There are some Himalayan species of Crawfurdia, notably C. affinis and C. speciosa. *K. Yashiroda, Japan.*

ALPINE GARDEN.

SCABIOSA PTEROCEPHALA.

For planting in sunny crevices on the rock garden or rock wall, S. Pterocephala, from Greece, might well be employed, as it forms a close, spreading mat of soft, silvery-grey foliage, for which splendid character alone it is worthy of a place.

It is sometimes referred to in catalogues and other works as Pterocephalus Parnassi, but this name, under which it was once more generally known, has now been superseded by the one given above, although it is very distinct from the other members of the genus, the flowers being the only character typical of the Scabious. The sheets of foliage are, during July, and if the plant is happily situated, covered with large, short-stemmed, pale lilac-coloured flowers, borne in great profusion and very attractive, and they, in turn, give place to grey, fluffy seed-heads, which enhance the charm of this subject during the late summer and early autumn months.

S. Pterocephala is essentially a plant for sunny crevices, for if grown on the flat, where the rain can beat down upon it and its foliage become saturated, its health may soon be impaired and, by the end of winter, it will present a very sorry and bedraggled appearance, while it may even succumb completely. It should be planted in the warmest and sunniest position possible, where the roots may penetrate to a good depth between the rocks, in light, gritty, loamy soil, and under such conditions should last for many years, spreading with moderate freedom and becoming, with each succeeding year, an ever widening mat of undoubted charm.

Other than its natural exception to excessive dampness—a character general to silky-leaved plants—S. Pterocephala is quite hardy, while it may be propagated successfully by summer-rooted cuttings.

MARGYRICARPUS SETOSUS

Among the lesser-known subjects which might be planted more freely in alpine gardens and on rock walls is the evergreen bushling Margyricarpus setosus, from the mountains and cooler parts of South America, and a member of the Natural Order Rosaceae.

It should be planted in a crevice, in a warm position and loamy soil, so that the woody, trailing growths, closely packed with small, greyish-green and very finely-cut foliage, may hang in a bushy mat. The flowers are insignificant and of no account, but they are followed by large, white, pearl-like berries—from which character this subject derives its popular name of the Pearl-berry. When these fruits are produced plentifully, as they are during warm summers, the bushlings are very attractive, especially when hanging against well-weathered rocks.

It is very seldom that M. setosus is damaged by severe weather—excessive wetness is likely to prove more harmful to it and for this reason planting it in a crevice on the face of a cliff, or rock wall is to be recommended.

It may be propagated by cuttings, taken in summer (I find that short growths, removed with a "heel," provide the best material), and inserted in a bed of sand in a cold frame. These do not root so quickly as many subjects, and care is necessary with them at this stage, or the portion beneath the surface level may rot off. When rooted, they should be potted in small pots, in sandy loam, and grown on and wintered in a frame, planting them out, if rooted well, the following late spring. *M. W.*

TREES AND SHRUBS.

KALMIAS.

There is a distinctiveness and charm about the Kalmias which enables them to hold their own in spite of the great inrush of other Ericaceous shrubs. All but K. latifolia are quite dwarf (under four feet) and so amenable are they to garden culture that they will thrive in any good lime-free loam or sandy peat, the former being enriched, if deficient in humus, with some well-decayed vegetable matter. A fairly cool, or moist, root-run is essential to the best results and the drainage must, of course, be free. But the Kalmias are really very easily satisfied, and any soil that will grow Rhododendrons will suit them. A little thin shade from the mid-day sun is desirable, but not necessary when the moisture is sufficient. All are evergreen, with the exception of K. cuneata, which has only been re-introduced recently after having been lost to cultivation in this country for nearly a century. This species is probably less hardy than the others, since it comes from the Carolinas. At any rate, the only specimen I ever possessed did not stay long, and I have not been able to replace it.

The other Kalmias are natives of eastern North America, extending to the central states and into Canada. The species most familiar to our gardens is K. angustifolia, an extremely variable shrub ranging in height from a little bush of a few inches to about four feet. The glossy, bright green leaves, paler beneath, are more oval, or rounded, than in the others, and they are borne in pairs or threes. As this shrub suckers freely it makes rather a close thicket of its slender, upright branches. The flowers appear from about midsummer onwards at the tips of the growths and remain for several weeks, often to the end of the season. They are produced in dense clusters, rather more than two inches across, and are shallowly bowl-shaped, with the five angular lobes peculiar to all the race. They are rich rosy-red, with just a hint of blue, which prevents them being so pleasing as they might be. There is a variety, rubra, which has deeper-coloured blossoms, and another very delightful form, rosea, which earns its name since its blossoms are a lovely rose-pink. K. a. nana (pumila) is the Benjamin of the tribe, being only some six inches in height, and its comparatively large flowers are a clear rosy-red. Then there is K. a. ovata, whose leaves are broader and of a duller green than those of the type, with flower-clusters as in the last-mentioned. I must add, however, that K. angustifolia and its varieties appear to be in a state of considerable confusion regarding identity and nomenclature, the compilers of catalogues, and even authorities in botanical gardens, displaying very divergent opinions.

Although K. angustifolia suckers, it is not aggressive in that respect. With me, at any rate, it spreads very slowly and always keeps to a more or less self-contained clump. That being so, I do not hesitate to use it among choicer plants at the margin of the bog, or in cool beds with any of the smaller Gaultherias, Shortias, and the like. So much may also be written of K. glauca, which has a similar habit of growth. But this comely little shrub is finer in stem and leaf than the foregoing, and can at once be distinguished from the dwarfer forms of K. angustifolia by its much narrower leaves, the dark lustrous green of their upper sides and the very glaucous, almost white, under-surfaces. These leaves, moreover, are tapered and more pointed at both ends than those of the varieties mentioned, they are recurved at the margins and their stalks are pressed against the branch. K. glauca does not often exceed eighteen inches. It flowers prolifically, the blooms, which appear in April, and often to some extent in late summer, being borne in bold, terminal clusters. They are a deep saucer-shape, with the five lobes referred to, and of a vivid rosy-purple. This little shrub will do in almost any cool soil, even in the rock garden, but it is happiest where it receives ample moisture. In the Rockies I have seen it growing and flowering actually in shallow water at the stony margins of lakes, and there is no doubt but that it is by nature a swamp dweller. It is one of the most delightful of the smaller Ericaceous shrubs.

K. latifolia is not only the finest of the genus, but a shrub that must be accorded a foremost place among the choicest and most beautiful of all shrubs, not excluding Rhododendrons. In its native North America it varies in stature according to the location, being anything from four to twenty-five feet tall, but in this country the average height of well-matured specimens is from seven to ten feet, with a symmetrical, rounded form and a width about equal to the stature. There is a superficial resemblance to a Rhododendron in the habit of growth and in the leathery, smooth, dark-green, oval, pointed leaves, which are often nearly six inches long. The flowers, borne in large clusters at the ends of the twigs in early June, are about an inch across, the five-angled corollas being anything from a pale blush-tinted white, to a deep rose-pink. Even before the flowers open, K. latifolia is an attractive plant, with the vivid tints of its waxen buds against the rich and lustrous foliage, but a well-grown specimen in full bloom is an object of peerless loveliness and one possessed of a refinement of the rarest quality.

The most beautiful colour form of K. latifolia is, to my mind, a medium rose, keen and pure, which dies off in a shell-pink, rather than the white of the paler ones. These colour forms are not offered separately under name by the trade, presumably on account of this species being propagated from seeds. However, it is always well, when ordering K. latifolia, to specify the shade of colour required; it is still better to see the plants in flower in the nursery, for there is also a considerable difference in the size of the blooms and the truss. There is a variety, K. l. myrtifolia, with smaller leaves and a much dwarfer habit.

K. latifolia does very well in an average, lime-free loam that is well-drained and on the light side. Under such conditions, it is a long-lived shrub and flowers regularly. I know of one specimen, believed to be about one-hundred-and-fifty years old, which is still vigorous, and for the past forty years it has, to my knowledge, flowered abundantly every season. It is growing with the turf of the lawn up to its base and has never had any attention in the way of feeding.

The flowers of the Kalmias are worthy of more than passing notice, for the mechanism by which fertilisation is secured is ingenious. Thus the stamens, when the flower first opens, are bent back so that the anthers rest in the little cups which form the angular corners of the five-lobed corolla. If the stamen is touched, the anther being ripe and the day warm, it is immediately released and, with the action of a catapult, pelts the visiting insect (or one's pencil point) with pollen.

The Kalmias are propagated by seeds, division (or suckers) or cuttings. From all kinds which sucker it is often an easy matter to detach rooted growths, but as K. latifolia usually grows from one or more stout stems, which are not so apt to produce available suckers, it is increased from cuttings or seeds. The former are, of course, the more preferable where one wishes to perpetuate a good colour form, and they are not difficult to manage. A fair percentage should strike if four or five inch lengths of the young wood are taken in August, inserted in very sandy peat in a cold frame, and left covered by a bell-glass until the following spring. *A. T. J.*

TRACHYCARPUS EXCELSA.

The hardiest of Palms in this country is Trachycarpus excelsa, once a very popular subject and still very widely grown for the decoration of cool conservatories and winter gardens. In the south of England, and even at Kew, where conditions are often very severe and damaging to plants, Trachycarpus excelsa has withstood the winters of half-a-century, and suffered little or no damage, although often unprotected. In Cornwall and south Devon, the Chusan Palm is grown somewhat extensively in both public and private gardens, and quite considerable plantations of it were made in clearings in an Oak wood, at Bosahan, by the late Sir Arthur Vivian. It is the only Palm referred to by Mr. W. J. Bean in his *Trees and Shrubs Hardy in the British Isles*, and he states that established plants will withstand 32° of frost.

Trachycarpus excelsa deserves shelter from cold winds, and when so protected its elegant, long-persisting leaves are not discoloured or torn, and consequently form a distinct attraction, particularly to any part of the garden wherein the aim is to obtain a sub-tropical effect.

The popularity of this Palm—originally discovered in Japan by Siebold, who sent seeds to Leyden in 1830—is suggested by the numerous names it has received. In gardens, its most popular name is Chamaerops Fortunei, a reminder that Robert Fortune introduced plants to Kew in 1849, and with some of these the earliest experiments were made to test its hardiness, for at Kew it had previously been cultivated in the tropical Palm House. Other names include those of Chamaerops excelsa and Trachycarpus Fortunei. The example illustrated in Fig. 13 is growing in Mr. Gunther's garden at Tongswood, near Hawkhurst, Kent, a garden that was described and illustrated in *The Gardeners' Chronicle* during the second half of 1925. *B.*

SOPHORA TETRAPTERA.

This distinctive and very attractive shrub is usually grown on a south-west wall, and in spring its large racemes of yellow, Pea-shaped flowers are particularly striking; the racemes are axillary and pendulous. The leaflets, arranged in heavy, opposite pairs, are silky, densely so on old plants, and the species, in favoured localities, will attain a height of twenty or more feet. S. tetraptera was introduced from New Zealand in 1772.

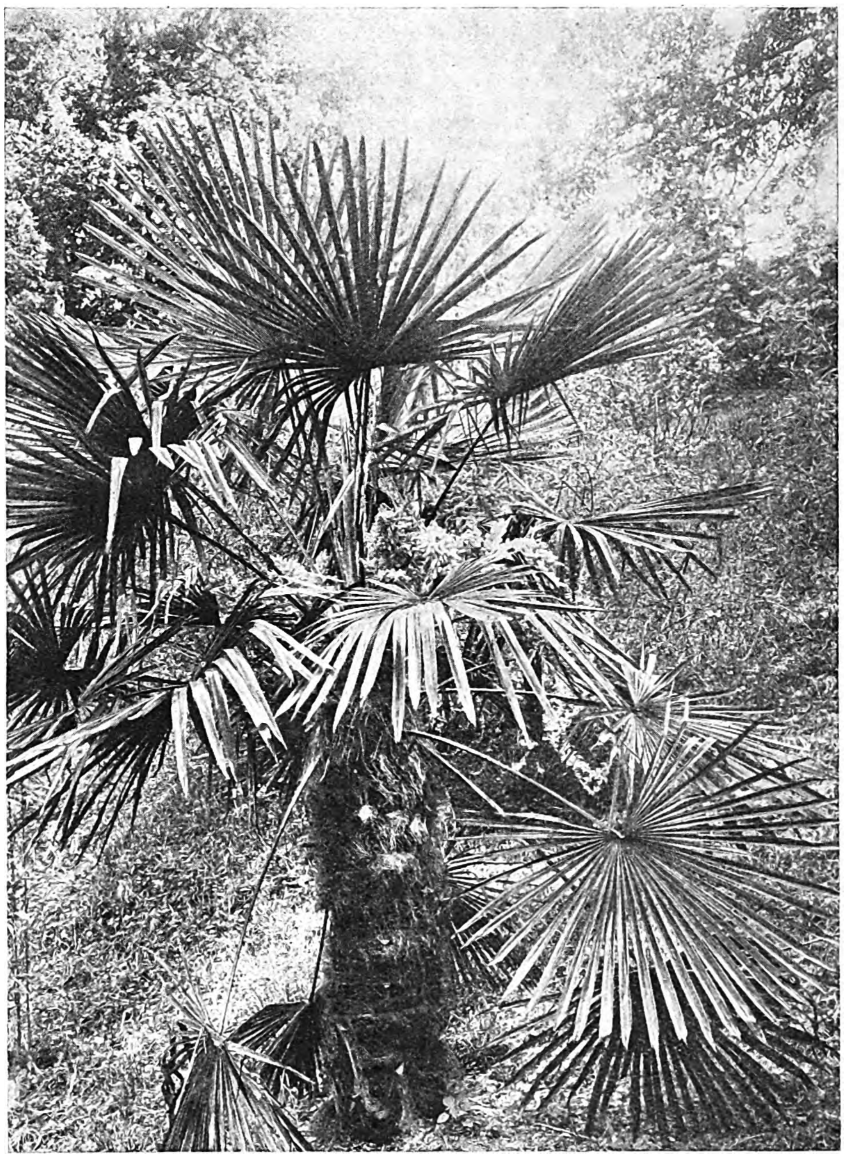

FIG. 13.—TRACHYCARPUS EXCELSA AT TONGSWOOD.

S. t. microphylla, the New Zealand Laburnum, is hardier than the type, and in mild localities will grow well as a bush, in addition to being an ideal wall plant; somewhat smaller of leaf and flower than S. tetraptera, it is otherwise very similar to it, and is figured, under the name of Edwardsia Macnabiana in *Bot. Mag.*, t. 3735, and as E. microphylla, t. 1442.

S. t. grandiflora, familiar to many as Edwardsia grandiflora, is a robust form requiring the favourable conditions appertaining to a south or south-west wall; this form is figured in *Bot. Mag.*, t. 167, as S. tetraptera.

These interesting New Zealand shrubs are easily propagated from cuttings in summer, and although of somewhat slow growth are always attractive; they thrive in a well-drained, loamy soil, enriched with humus, and respond to generous treatment. *Ralph E. Arnold.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

LILIES IN 1928.

EXCEPT that the winter of 1927-8 stretched its tail to an inordinate length and crippled the June-flowering group, the Lily season of 1928 will be remembered as the best the south of England has enjoyed for many years. From the beginning of July onwards to the end of the autumn, the weather, on which everything depends, was generally and enjoyably fine in the south as distinct from the north; and although the want of rain made itself felt here and there on some of the higher, lighter land, a pleasant downpour on July 27 had a most refreshing effect, and there was enough water in the ground when the drought began in early July to last out. That, and the unfavourable spring, were the essential distinctions between 1928 and 1921. In the latter year the average heat of the summer months was a good deal in excess of that of last year, and the drought had made itself felt in all directions in the south by the end of July.

In a letter dated June 22 to a friend, I wrote: "The longest day has come and gone, and so far the season for Lilies is about the worst of the many bad ones I have known. Botrytis is everywhere, and if the sun does not shine soon the early and mid-season species will be spoiled. It is seldom that two hopeless seasons follow each other, so let us hope we may yet be spared that calamity. But the sands are running out."

Up to the end of June the season was so backward that the earlier-flowering group of Lilies was unusually delayed, and then, when the hot weather began, found themselves in bloom with the July-flowering group, which, in turn, was forced by the hot weather of the second week of that month. So we had the unusual spectacle of L. pomponium and L. Hansonii and the other "first earlies" in flower with L. croceum, L. Martagon and L. monadelphum. As is usually the case, too, in a fine summer, the normal gap between the July-flowering group and the early autumn species was bridged; and once again, the sun showed its power over botrytis, for by the middle of July all active trace of the pestilent fungus had gone.

Of the first few months of the year the story is one with which southern gardeners are familiar, for it has all happened before, although not, perhaps, in precisely the same sequence. During a short, warm spell at the end of February, Forsythia suspensa was in full bloom in Hyde Park, earlier than usual. Easter was delightfully fine, with warm southerly winds, and the next week was bitterly cold with icy winds from the north-east, snow and frost. On March 10 a severe frost reduced the bloom of early Rhododendrons to brown pulp, even in gardens within sight of the Channel. The frost was followed by a heavy fall of snow, which covered the south coast from the North Foreland to Cornwall; and next day the temperature at Kew Observatory was the coldest registered in March for thirty-six years.

On the other hand, there were the usual preludes to summer, which, with the wintry spells, go to the making of that composite picture—the English spring; and although the recollection of its asperities was not blotted out by the summer, the latter went far to soften the remembrance of one of the worst vernal seasons of the century. Happily, the blizzard and intensely cold spell which froze the south just after Christmas of 1927 did no harm to Lilies. None of them was showing above ground at the time, and although frost will cripple the young stem growths of Lilies, it does the bulbs no harm; in fact, as has been remarked before in similar notes, observation seems to show that they are the better for a freezing, even to balls of ice.

The pleasant rains of October were not enough to spoil the harvest of seeds, which seems, generally, to have been bountiful and should encourage amateurs to raise their own crops. American gardeners, who have lately taken to Lilies as eagerly as they took to Roses, Irises and Paeonies years ago, have been quick to appreciate the benefits of the propagation of Lilies from seeds, and with the help of illustrated leaflets issued by the United States Board of Agriculture, great numbers are now raised annually in this way in the United States. If British nurserymen do not look to their laurels, it may not be long before American-raised bulbs of Lilium regale are offered here at favourable prices. This species can be brought to marketable size in two years, by which time the bulbs should be of Walnut size, and it should be possible to sell such bulbs at 1s. apiece. It is true that, knowing no better, amateurs clamour for larger bulbs, but it is doubtful if these move so well as smaller bulbs. Experience seems to show that third-year bulbs of L. regale usually transplant more satisfactorily than those of greater age; a good deal depends, no doubt, on the season, on the method of handling, and the time the bulbs are out of the ground, but the fact remains that the original consignment of bulbs of L. regale which Wilson collected in China and sent home, made a fine show the following summer. But England is not China.

Although, perhaps naturally, they seem to have an extraordinary attraction for the unwary, large bulbs of L. giganteum are notoriously bad movers, and here again third year bulbs, which are usually about the size of a two-ounce hen's egg, are most satisfactory. It is the same with L. monadelphum var. Szovitsianum, and like L. candidum, that should be transplanted early in the season. L. Hansonii is one of the few species which may be lifted at almost any age, without apparent hurt. The roots of some Lilies seem to remain active even when the bulb is resting, and L. Henryi is an example, while in some others the roots are annual and perish so soon as the bulb goes to rest. The latter obviously transplant more happily than the former class, because they may be lifted without disturbance of the root system. The subject is one on which there is need for research, and pot-grown bulbs should assist the process.

Some Lily bulbs rest for prolonged periods, while others take hardly any holiday. L. candidum is the classic example of the latter, and that comparatively little-known species, L. Sargentiae, makes no move from the time it goes to rest in late October until the end of February, and may be kept all but bone-dry during that period. Yet bulbils of the species keep their leaves all through the winter; in fact, are evergreen! These are points which catch the eye of the observant grower, but they make conclusions difficult.

Having reached the time when but slight addition can be made to the list of known Lilies, it is pleasant to be able to write hopefully of F. K. Ward's pink Martagon Lily, No. 6,034 (*Gard. Chron.*, 1927, Vol. LXXXII, Fig. 55, p. 127), which has made further progress during the year, and should soon be in the hands of many amateurs. Visitors to Vincent Square will recollect the exhibits of this species sent by Lt.-Col. Messel from his garden at Nymans, where there has been a colony of it for two years, but no one would have supposed it capable of the growth shown in the photograph kindly sent to me by the Hon. H. D. McLaren (Fig. 14) of a remarkable young specimen grown in the open at Bodnant. As often happens with Lilies in cultivation and, particularly, with that florifer-

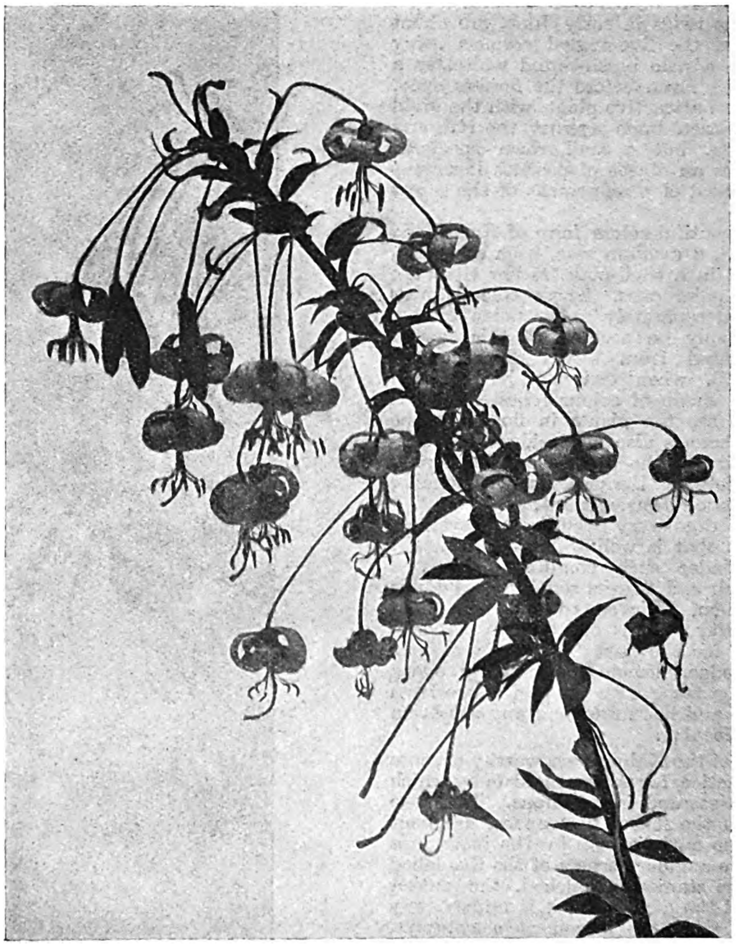

FIG. 14.—LILIUM SP., F. K. WARD, No. 6,034 AT BODNANT, 1928.

ous species, L. Willmottiae, the weight of flowers was evidently more than the slender stem of the specimen could comfortably support, and the photographer had either to make a record of the leaning stem or leave it. Those who know their Lilies will notice a certain general resemblance of the Lily in the photograph to the habit of L. Willmottiae, but there the resemblance ceases, for the plant is certainly new. At first Ward's Lily seemed to have some relationship with Franchet's L. taliense, but critical investigation showed it to be illusory. The species has still to be formally described and named, and as the name of the discoverer is as yet unattached to any Lily, the opportunity presents itself of paying him a graceful compliment.

This Lily has yet to prove itself a good garden plant, like L. regale for instance, and the fact should be borne in mind that Lilies with small bulbs like this rarely make satisfactory plants for general use. But the exception may prove the rule, and the species has two great virtues—a generous production of seeds and quickness of growth. It may be had in flower in the second year from sowing the seeds. Whether it is calcifugal or not remains to be proved, but the indications seem to show that it is not.

The same may certainly be stated of L. centifolium, which seems slow of distribution in this country, although American gardeners are cultivating it assiduously and successfully, both from seeds and by scale offsets, as the illustration (Fig. 15), kindly sent to me by Mr. Griffiths, of the U.S.A. Board of Agriculture, shows. The capsule is naturally large and holds hundreds of fertile seeds, with a moderate amount of chaff. I have watched some isolated specimens of this Lily for years, and as they never form seed capsules, one may conclude that it is sometimes self-sterile. In such cases, the stock may be increased easily by removing the outside layer of scales from the bulb and "sowing" them in a pan or pot. The removal of the scales can be managed by nimble fingers without lifting the bulb or doing it any harm. In the case of old bulbs, which may be so much as six inches in diameter, two or three layers of scales may be detached without harming the bulb.

In such a summer as that experienced in 1928, several Lilies which normally mope in our climate, come into their own, and so it was not surprising to find L. ochraceum making more than one appearance at Vincent Square, as well as L. sulphureum, which after a total eclipse in the wet summer of 1927 was in good form last year in many directions. There is a good colony of the former Lily in the garden at Logan, where, Mr. McDouall tells me, it is perennial, and where, incidentally, what must surely be a record head of L. japonicum, with nine blooms, flowered last summer. L. Wallichianum, too, made one of its furtive appearances last year. In our southern climate all these species, as well as L. philippinense and the varieties of L. auratum—Wittei, pictum, cruentum and rubro-vittatum, are best with a roof over their heads, as then one may see them in all the purity of their natural colouring, and that is wonderful.

During the year, a variety of L. auratum platyphyllum, called rubro-vittatum, flowered in several directions from bulbs marketed by the Yokohama Nursery Company. Whether this is rightly attached to L. a. platyphyllum or is a variant of the rubro-vittatum form of the type (L. auratum) is not clear; but, as grown here, it certainly lacks the broad leaves and bold habit of L. a. platyphyllum. For some hours after the bud has opened the rich chocolate colouring of the petal is very satisfying, but the tint is most fugacious. The variety seems no easier to keep than the other.

That elegant Himalayan species, L. polyphyllum, must be a stranger to the younger generation of Lily growers, although it was by no means rare twenty years ago. In those days it was usually to be found in one or other of the glasshouses at Kew, and Mr. Elwes, who knew the plant in its natural habitat, generally contrived to keep it going under glass. The writer, too, had a colony of it for some years in the open in his garden, from home-raised bulbs, and raised further stock from the seeds of the colony, which persisted until an enterprising mole tunnelled under the group and under an adjacent clump of that rare beauty, L. Bolanderi (Fig. 16), bringing each to an untimely end. Bulbs of L. polyphyllum reach this country from time to time from Darjeeling or Simla or Jeol kote, but they do not travel well and rarely recover from the ordeal. Seeds of the species, however, were included in the representative parcel of Kashmir seeds, sent last year to His Majesty the King by the Maharajah of Kashmir, and were distributed by the Office of Works; so, in a few years' time, we may hope to see L. polyphyllum in the flesh again.

During the year, Wright has investigated the common fungus disease of Lilies which is so prevalent in damp seasons, and has reached the conclusion that it is not Botrytis cinerea, as generally supposed, but a distinct and novel species, for which he proposes the name B. elliptica.* Ogilvie, too, who has done noticeable work in the investigation of the Bermuda Lily disease, has found that although the fungus botrytis was present in the Bermuda fields in damp seasons, it was not primarily responsible for the decay of the Lily industry in the island, an industry now happily resuscitated. The cause is to be found in a virus disease transmitted by a particular aphis, and possibly introduced to Bermuda from Japan.† A most important discovery. *A. Grove.*

SELF-FERTILE, CONSTANT-CROPPING, AND SEEDLING FRUIT TREES.

IN KENT, SURREY AND MIDDLESEX.

THESE notes do not purport to be determinative. They treat of thirty-five years' experiment in one Middlesex garden of small size in which the number of seedling trees which could be grown to fruiting size was limited. But they throw some light upon the subject, and have been supplemented by similar observations from Kent and Surrey gardens.

There are two schemes which have been tried elsewhere. What may be called "the broadcast plan" was first put on record in the United States of America by Burbank, who, having access to big fruit farms in which hundreds of trees of each variety were grown together, collected quantities of seeds without discrimination as to male parentage. The scientific plan, on the other hand, necessitates the depollenization and bagging of the female, and the recording of the pollen artificially used for impregnation. Both schemes suffer from limitations. Burbank's scheme could only yield results of genetic reliability if seeds could be collected from the middle of a large area planted with only one variety of fruit tree. The scientific plan demands an amount of expert labour well suited to the activities of a subsidized horticultural establishment, but which is, if carried out on a large scale, beyond the compass of a single amateur unable to give his undivided attention to this work.

It therefore became a question of compromise to evolve a scheme which was both practical in operation and which would give some results of value. It was not possible to secure that practical immunity from chance cross-fertilisation which Burbank wished to secure from collecting seeds in the middle of a big area devoted to one variety of tree. But it is known that in general (and excluding races of garden mongrels which have for generations been crossed in all directions), flowers which are pollenated with "foreign" pollen fail to carry the normal number of seeds, and fruits containing less than the normal number of seeds will not swell to the normal size (the Citrus group furnishes some exceptions). On this basis it is clear that if fruits of extra large size and perfection were chosen, it would be tolerably certain that they had been either selfed, or pollenated from another tree of the same sort or species. Although there may still be an element of doubt here, yet, if from seeds so chosen, trees are raised which are indistinguishable from the female parent, the probability is that the female parent belongs to the class of self-fertile trees. For, even if we are confronted with the parthenogenic argument, yet trees which can reproduce themselves in this way are, for the gardener's purposes, self-fertile. This line of argument applies to Apples and Pears, but clearly not to stone fruits. I therefore worked on these lines, sowing only seeds from extra fine specimens of fruits chosen from but a very few of the best varieties.

† "A Transmissible Virus Disease of the Easter Lily," by Lawrence Ogilvie, M.Sc., M.A. *The Annals of Applied Biology*, Vol. XV, No. 4 (1928), p. 540.

Those who would criticise my methods should bear in mind that there is a fundamental difference between hybridising plants and trees grown for the sake of their flowers, and those grown for fruiting purposes. If one depollenates and hybridises the flowers of a fruit tree, there can be no assurance that the fruits which would naturally have been formed on the flowers selected would have been either specially well-flavoured or well developed. But by the method I have employed, both flavour and size had been determined without doubt. In the former case, one takes the risk of hybridising flowers on a spray which has some hidden defect in capacity for fruit formation; in the latter case there is the risk of a chance cross by inferior pollen. There does not seem to be any larger element of luck in one scheme than in the other.

Among Apples, I used Cox's Orange Pippin, Ribston Pippin, Improved Gravenstein, and Cellini; among Pears, Doyenné du Comice and Marie Louise; and among Plums, Coe's Golden Drop, Reine Claude de Bavay, Jefferson, Oullins Gage and Victoria.

QUALITY AND USE.

PLUMS.—Oullins Gage has the richest flavour among the earlier Plums grown here, and Coe's Golden Drop (including both seedlings from it), and Reine Claude de Bavay among the later kinds. My seedling Victoria is very sweet and juicy, but has not the aromatic qualities of the former three. But it has size, some fruits weighing four ounces, and many three ounces and over.

Among cookers, none can touch Belle de Louvain for richness. Czar and the old Winesour are also good, especially for jam-making. Damsons do not succeed here. For bottling it is useless to grow any Plum which does not possess considerable acidity in the skin. Non-acid Plums, when bottled, become maukish in a few months. The Cherry Plum (Myrobalan) is second to none, but does not succeed here.

PEARS.—None can compare with Doyenné du Comice, either in flavour or in the long period during which it remains ripe without decaying. Marie Louise and its seedlings come a good second. I have had fruits of the latter weighing up to nine-and-a-half ounces in the open. Although this delicious Pear is shown at practically every fruit show, it is never obtainable in shops. Uvedale's St. Germain is, perhaps, the best cooker. The soil here has long been known as suitable for Pears.

APPLES.—Cox's Orange Pippin and its seedlings are the highest flavoured. The old green-skinned Ribston Pippin is the next best if it is eaten off the tree, but when stored it loses much of its aromatic quality. I have two early seedlings of merit. A seedling of Newtown Pippin is unrecognisable as such. Among white-fleshed cookers, Keswick Codlin as an early, and Lanes Prince Albert as a long keeper, take a lot of beating. No small garden should be without Cellini, on account of its general utility and constant cropping characters.

SELF-FERTILE AND CONSTANT-CROPPING SORTS OF FRUIT TREES (see list on p. 33).

The characters of seedling trees depend upon the declared or latent characters of their parents, hence it is important to trace back such characters to the parents, wherever possible. But it is known that all classes of flora which have been propagated for many "generations" by non-sexual means, tend to lose their sexual virility. To such a marked extent is this true, in some cases, that Sugar canes which had been propagated by sets for a very long time had lost all power of bearing seeds. It is only in recent years, and after careful search, and culture in horticultural establishments, that new sorts of Sugar cane have been produced and promise to double the Sugar crop.

We may, therefore, assume that seedling trees have, in general, recovered whatever fecundity their parents originally possessed, and that near-crossed seedlings will generally be self-fertile. Seedling Orange trees carry such quantities of seeds, that the edible value of their fruits is seriously depreciated, whereas the best forms of nearly seedless Oranges are the product of a century or more of non-sexual reproduction. A few exceptions are on record.

In order that those engaged in studying this interesting subject may be in possession of results obtained in various gardens, I corresponded with Mr. W. Poupart, Mr. C. H. Hooper, and Mr. F. J. Chittenden, and drew out the list (on p. 33) of self-fertile and constant-cropping sorts. It must not be thought that these authorities and myself were of the same opinion in every particular instance, because trees may be constant-croppers in some situations and not in others. Moreover, some trees have been proved to be self-fertile by experiment in certain situations only, and have then been assumed to be self-fertile in all situations, which assumption may be unwarranted.

It will be noticed that, outside my own garden, few recent seedlings appear on the list, as such seedlings are not in general cultivation. But experimental growers will obtain from this list the characters of many well-known sorts of fruit trees, which some of them will use as female, or as pollen-bearing, parents of seedlings.

Seventeen years ago lists of fruit trees which had been tested for self-fertility were made out, and showed that seventeen per cent. of Apples, thirteen per cent. of Pears, forty-five per cent. of Plums, and twenty-two per cent. of Cherries were self-fertile. I raised objections to this list because it did not accord with my own observations of the percentage of constant-cropping sorts compared with trees that carried occasional or variable crops, and which seemed especially faulty regarding Cherries. Recent tests have given very variable and partly contradictory percentages, and, in my opinion, we are still far from having obtained reliable figures.

Mr. C. H. Hooper, using the method of bagging the sprays, gave, in 1925, the following percentages out of sixty sorts of tested Apples:—Self-fertile naturally, rather over three per cent.; self-fertile, when self-pollenated, about 18·5 per cent.; and fertile, when cross-pollenated, about eighty per cent.

But the problem is far too complicated for any solution on these lines to be valid. For instance, the bloom carried on all orchard fruit trees is far in excess of their fruit-carrying capacity. The late Dr. Masters studied this question. When he visited my garden he told me that if an Apple tree carried fruits on twenty per cent of its blossoms in a normal year, this would be a full crop, and anything in excess of this would be an over-crop. I am now convinced that twenty per cent. is a generous estimate and is rarely reached in our climate. In the case of Pears, the percentage of blooms carrying fruits is much less than this, and in the case of Plums is nearer five per cent. than ten per cent. Hence, to prove self-fertility by bagging, a large number of sprays must be bagged on every sort tested. But there are two other matters which demand attention. In orchard Apples, it is the upper part of the tree which carries the greater part of the crop and also the larger fruits, and this is doubtless due to the upper part of the tree getting more direct sun-light than the partly shaded lower portion of the tree. To make a fair test it would be necessary to ascend steps or a ladder to the upper branches in order to bag, and attend to the sprays under observation. Secondly, the bagged sprays would, in any case, suffer just those limitations to which the shaded part of a tree is subjected, inasmuch as the bag interferes with direct sunlight. Hence, it is obvious that the percentage of those Apples, whose self-fertility has been proved under these restricting influences, should be raised by some yet unknown factor.

Climatological causes have an incalculable effect in causing a reduction of a conceivably possible maximum crop to that actually realizable.

As to Marie Louise Pears, I have noted that, during the few days that the stigmas are ready for impregnation, a maximum day temperature of 60° or more was necessary for fertilisation. To the usual deficiency of day temperatures during the flowering period, I trace the erratic cropping of this excellent Pear. Apparently this is not due to any deficiency of active pollen at lower maximum day temperatures than 60°, but to some lack of receptivity of the female organs at lower temperatures. We should realise that the influence of climate may be predominant in deciding the question of fertility, and that in some cases the question of self-fertility and of receptivity to foreign pollen may occupy a relatively unimportant place, and be overborne by the factor of climate.

As a rough approximation of the percentage of self-fertile fruit trees, in some places and under optimum weather conditions, the following table may be of value, but much will depend on the locality and the sorts grown:—Apples, about 33 per cent.; Pears, from 10 to 15 per cent.; and Plums, from 30 to 40 per cent.; Cherries, only two varieties are constantly self-fertile, and two others in some degree; Peaches and Nectarines are typically self-fertile; Apricot Moor Park is self-fertile (no other sort has been tested); and Quinces are typically self-fertile.

It appears from the Apple list that all undoubted self-fertile sorts are also constant-croppers, and that my seedlings are all constant-croppers.

Four self-fertile Plums are listed as constant-croppers (p. 33). Among those Plums which only carry good crops at rare intervals in my garden are Jefferson, Coe's Golden Drop and its two seedlings, Oullins Golden Gage, all sorts of Damson, Prunes, Reine Claude de Bavay, Japanese sorts (four), and Cherry Plum.

It is not an ideal soil for Plums. They generally suffer from lack of moisture at the period of foliation, and often from excessive rain at harvest time.

Cherries do not succeed at Isleworth, and are not much grown in this district. Morello is an exception, and carried crops every year until Cherry cultivation was given up on account of shortage of ground.

No cooking Pear carries constant crops at Isleworth. Those sorts condemned in my garden were either small-fruited kinds of no particular merit, or ripened all their fruits within a period of a few days, and so were of no use in a private garden. Many sorts of Pears were condemned for this latter reason, although they may be suitable sorts for market purposes. This is a very good Pear soil. The list (see p. 33), is too short for any definite conclusion to be drawn as to whether self-fertility and constant-cropping are interconnected.

NOTES ON SEEDLING TREES.

PEARS.—About two-thirds of the Pears are valueless; some of these have too small fruits, some must all be used in two or three days as they have no keeping quality when once ripe. All of them possess some acidity, which is only pleasant when there is ample sweetness to carry it off, which is only the case in some seedlings. About three per cent. may be worth naming. Only one seedling was a dwarf tree on its own roots, and this is a very good-flavoured Pear.

I have had Marie Louise come true from seeds, but Doyenné du Comice has never done so, and its seedlings are unrecognisable. Seedlings come into bearing in twelve to eighteen years. The flowering period of most sorts of Pears extends over about twenty days. No account is taken of the second flowering period on new wood which sometimes takes place in June.

APPLES.—About half are worth growing. Their quality and size of fruit average about the same as their female parents, and their keeping qualities also. I have only one which is a rampant grower, and some are on the dwarf side. Two or more of Cox's Orange Pippin have come true from seeds, but Ribston Pippin and Newtown Pippin are unrecognisable. An improved Cellini is near its female parent. Besides the seedling Cox's Orange Pippin, I have raised two others of first quality—an early dessert

Apple and a very heavy, prolific cooker. Seedlings come into bearing in about eight years. The flowering period, being later than that of Pears, is often shortened by a spell of high temperature. In cool weather it is roughly about twenty days, or rather less.

PLUMS.—Most of them are worth growing. Their quality, size of fruit and height vary widely. Some carry small, Damson-like fruits, sweet in some cases and tart in others. Some are constant-croppers, others are as uncertain as their female parents. Some carry three flowers together, some carry a bunch of many flowers which one cannot separate with certainty, while others carry their flowers singly or in pairs. The self-fertile Victoria produced a self-fertile, very early-flowering, constant-cropping seedling, with larger and better-flavoured fruits. Coe's Golden Drop produced some seedlings of high flavour, uncertain croppers, and the like, but easily distinguished from, itself. Reine Claude de Bavay rarely carried fertile seeds. The seedlings of Oullins Gage and of Jefferson are so far unrecognisable. I have about four worth naming. My seedlings have not suffered to any extent from silver-leaf, and have come into bearing in from five to nine years.

I kept some in pots until flower-buds were seen, and then planted them out. These dwarfed trees have remained of dwarf growth ever since. Suckers of seedlings produce trees quite as good as the seedlings. The Pershore Plum has long been propagated in this way, and I have propagated seedling Victoria by suckers with success. The flowering period of Plums generally is two to four weeks, depending on temperature. No account is taken of the second period of flowering on the new wood in June.

APRICOTS.—Moor Park has produced seedlings true in all respects to the female parent, but more vigorous. It takes seven to nine years to reach the fruiting stage. The flowering period lasts three weeks, but blooms expanding after foliation has begun never carry fruits.

PEACHES AND NECTARINES.—I raised a first-class Peach from Alexander Noblesse, carrying fruits up to nine ounces, and a first-class Nectarine, carrying crops out-of-doors, from Violet Hâtive. About six years from sowing seeds should be allowed before fruits can be expected, if the seedlings are grown outside, but a year less under glass. Some are rampant growers which are difficult to accommodate on a wall. A few have a prolonged flowering period, which is a point of great importance for trees grown on walls without other shelter from spells of bad weather.

MULBERRIES.—It is not true, as has been asserted, that Mulberries do not reproduce themselves from seeds in England. My two trees occasionally bear fertile seeds, but the seedlings are very difficult to transplant.

TRANSPLANTING.—If strong-growing, seedling trees of all kinds are replanted about every second or third year, they will come into bearing sooner, and their height and the space they occupy will be lessened.

PRUNING.—In their juvenile state, the proper method of pruning is quite different from that suitable to fruiting trees. As there are no fruiting spurs, no spurring back should be attempted. But every year some juvenescent (barren) boughs nearest the ground should be cut off flush with the main stem. Seedlings cannot be "got into shape" until flowering branches are visible.

GRAFTING.—Most gardeners detest the irregular appearance of seedling fruit trees growing upon their own roots, and class them as wildings. I have had a few seedlings grafted or budded upon dwarfing stocks so as to economise room. As one would expect, these grafted trees were not so lanky as the original seedlings, and, in the case of Apples, carried a larger crop for the size of the tree. But there was no difference either in the size or quality of the fruits.

DEPTH OF ROOTS.—In this naturally porous soil, which has had all its clayey content washed out by centuries of cultivation, it has never been necessary to root-prune any fruit tree. On the contrary, the difficulty is to obtain enough roots at a certain depth so that the trees should not be crippled by drought at the period of foliation. Hence, it is probable that, in this garden, seedling trees on their own roots will outlive grafted trees, and will carry better crops in years of late spring droughts. This is a matter worth consideration for those whose orchards are situated in a zone of severe spring and summer drought, such as occur in many continental areas.

PESTS AND DISEASES.

It is known that hard-fruited Apples suffer least from maggot, and that soft-fruited kinds, such as Keswick Codlin, suffer most. But there are some moderately hard kinds which suffer sadly from maggot, and in some seedlings the same comparative immunity or special susceptibility is noticeable.

American woolly aphis also shows partiality to certain sorts of Apples, and will occasionally ruin seedling trees when they are only in their second year of growth.

Seasonal influences are of great importance. During the heavy summer rains of the war years, woolly aphis practically disappeared from my garden, but reappeared during the comparatively dry summer of 1928. Heavy thunder-rains in April and May are adverse to the Apple maggot. The season of 1926 was unique in my experience at Isleworth, inasmuch as there was an almost complete failure of the Apple crop. As a result, there were scarcely any Apples in which the maggot could develop and in 1927 we had a record Apple crop with scarcely a bored fruit to be found.

The methods of combating these pests are well-known, but cannot always be put into operation at the proper season in small gardens in which labour is limited.

One occasionally finds Pear midge, but it is easy to eradicate if taken in time. Wasps and the blue tit are not so easy to deal with. Plum maggot has never assumed serious proportions since the destruction of Pond's Seedling, which sort is specially susceptible. Isleworth is in the middle of the silver-leaf district. I believe that the endemic character of this disease is due to the expense of digging up old, diseased Plum stocks. Summer pruning will also spread the disease by the knife or other instrument made use of. But to cut off a diseased bough and tar the stump will generally suffice. On the other hand, if the disease is from the stock it cannot be combated. I have a case of a seedling Plum becoming diseased, but it is very rare. Gummosis in Apricots has puzzled us all.

CONCLUSIONS.

The time given to raising seedling Apples and Plums is not wasted, even if it cannot be called profitable. But with Pears it is another matter. They take twelve to eighteen years to fruit, are mostly rampant and straggling growers, and few are as good as their parents.

From an economic standpoint the raising of seedling fruit trees is not likely to prove remunerative. The main difficulty is not the time required to bring the seedlings to the fruiting stage, but the prolonged after-period, covering a whole lifetime, during which a named seedling has to struggle before it can obtain recognition in our markets as a standard sort. Until this recognition has been accorded, its fruits cannot be sold at any reasonable price. Fruits, other than Apples, suffer from uncertainty of crop. It is not possible for a small grower to continuously maintain the labour and equipment necessary for handling a good crop, which may only come once in six or seven years. Yet, if he does not do so, the raiser cannot improvise the equipment or obtain the labour enabling him to market a big crop when the occasion arrives. Hence, those politicians who, before the war, advised us to "grow more fruit," were addressing philanthropists, and not searchers for profitable enterprises. Still, we must remember that the great majority of named Apples and Plums now grown or imported into Britain were raised as seedlings in our country in years gone, by when the condition of affairs was not so adverse to the grower. *A. Worsley, Isleworth.*

MESEMBRYANTHEMUM.

(*Continued from p.* 493, *Vol. LXXXIV.*)

PUNCTILLARIA, N. E. BR.

P. Purpusii, N. E. Br. (*continued*)—Mes. nobile, Purpus in *Monasschr. f. Kakteenkunde*, 1907, p. 23 and 25, with fig., and in *Mollers Deutsche Gartn. Zeit*, 1911, p. 386 and 387, with fig., not of Haworth. M. magnipunctatum, Schwant. in *Zeitschr. f. Sukk.*, 1926, p. 160, not of Haworth.

Willowmore Division: Near Miller, Frith. Marloth 6,831.

Described from living plants. It is one of those I mentioned in *The Gardeners' Chronicle*, 1926, Vol. LXXX, p. 213, under P. magnipunctata, as being cultivated under that name. Its leaves, however, are usually less stout and more acute, and the long, slender, white bases of the petals give the flower a distinct appearance.

P. magnipunctata, N. E. Br.—To this should be added as a synonym, P. compacta, L. Bol. in *S. Afr. Gardening*, 1927, p. 326, f. 12, which bears no resemblance to P. compacta, N. E. Br. (=M. compactum, Ait.), and is merely a small form of P. magnipunctata.

P. optata, N. E. Br.—To this, I think, must be referred the plant wrongly identified with Mesembryanthemum canum, Haw., and figured as P. canum by Mrs. Bolus in *S. Afr. Gardening*, 1927, p. 326, f. 14. For the true M. canum, Haw., see under Bijlia.

BIJLIA, N. E. BR.

Perennial succulent, stemless or tufted. Leaves opposite, obliquely and clavately trigonous, strongly keeled, whitish. Peduncle not exserted from between the leaves, 1–3-flowered, bracteate. Flowers pedicellate. Calyx subequally 5-lobed. Petals 2-seriate, free, cuneately linear. Stamens numerous, in an erect column, exposed to view to their base. Stigmas 5, filiform. Ovary inferior, 5-celled; placentas on the outer wall of the cell. Capsule shortly and broadly obconic, flattish, with raised sutures on the top, with 5 valves and cells; valves of expanded capsule inflexed and separating but slightly from one another, not spreading; expanding keels small, slightly prominent, about half as long as the valve and without marginal wings; cells acutely roofed with slightly stiff cell-wings, with acute depressions between the ridges, and the opening nearly closed by a large tubercle. Seeds several in each cell, ovoid, pointed at one end.—N. E. Br. in *Journ. of Bot.*, 1928, p. 267.

A monotypic genus, native of South Africa.

The name is given in honour of Mrs. D. van der Bijl, who has very kindly sent to me specimens of this and other novelties. This genus is distinct in appearance, but more nearly allied to Cerochlamys than to any other genus.

1.—B. cana, N. E. Br.—Plant 1½ inch to 2 inches high, forming clumps. Leaves opposite, in 1–3 pairs to a growth, incurved-spreading, and as received, 9–18 lines long, 4–6 lines broad and 3–4½ lines thick at the base, and 5–9 lines broad and 4–8 lines thick near the apex, where the keel is dilated, clavately and often obliquely trigonous, obtuse, not toothed, flat on the face and often on one of the sides, the other side being (or sometimes both sides are) convex, strongly and usually obliquely keeled on the back, with somewhat sharp angles, firm, glabrous and smooth, whitish or whitish-green, not shining. Cymes 1–3-flowered, with the peduncle not visible. Bracts 1½–3 lines long. Pedicels 1–5 lines long. Calyx-lobes about 2½ lines long, lanceolate or ovate. Corolla 12–15 lines in diameter; petals numerous, about 6–8 lines long and ¾–1 line broad, cuneately linear, obtuse or notched at the apex, yellow. Stamens about 4 lines long, yellow. Stigmas 5, as long as or exceeding the stamens, filiform. Capsule as described for the genus, when closed 3–4 lines in diameter, and scarcely more when expanded, as the valves separate but slightly and remain inflexed, with the openings between them only ½–1½ line wide (not widely spreading as represented by Mrs. Bolus). Seeds ¼ line long, smooth, light brown, with a darker point.

N. E. Br. in *Journ. of. Bot.*, 1928, p. 268. M. canum, Haw., *Obs.*, p. 158, *Misc. Nat.*, p. 25, *Synops*, p. 219, and *Rev.*, 86, not of Salm Dyck, Berger nor Marloth. M. Tugwelliae, L. Bol. in *Ann. Bol. Herb.*, Vol. I, p. 129, and *Journ. Bot. Soc. S. Afr.*, 1927, t. 3., f. 6. Hereroa Tugwelliae, L. Bol., *Mes.*, p. 50–51, t. 20, and p. 143. Juttadinteria Tugwelliae, Schwant., in *Zeitschr. f. Sukk.*, 1926, p. 184. Bolusanthemum Tugwelliae, Schwant. in *Gartenwelt*, 1928, p. 514, and see also p. 644 under Bijlia.

Prince Albert Division: Among rocks near Prince Albert. Mrs. Tugwell, Mrs. D. van der Bijl. Introduced into cultivation at Kew by Masson in 1792, but soon died out.

Living specimens of this very neat and distinct-looking plant were sent to me by Mrs. D. van der Bijl early this year, and I at once recognised it as being the long lost M. canum, Haw., and also as the plant Mrs. Bolus has figured and described as M. Tugwelliae without having identified it with the plant Haworth described as M. canum in 1795, and which soon died out of cultivation, and appears not to have been refound for over 120 years.

Mrs. Bolus, however, as mentioned under Punctillaria optata, has wrongly identified a Punctillaria as being M. canum, Haw., which is quite incomprehensible, for the species of Punctillaria have dull, greyish-green or brownish-green leaves that are conspicuously-dotted, never "hoaryish" nor yet at all like "stunted toothless leaves of M. caninum." Haworth makes no mention of dots, and he certainly would have done so if they had been present. His description is as follows:—"Plant apparently stemless. Leaves 2 inches long, crossing each other in pairs, hoaryish (*i.e.*, whitish), subacinaciform, rather hard to the touch and turgid; triquetrous, compressed, attenuate from the middle downwards; sharply keeled; keel hunching out towards the point, which is roundish, with a sharp keeled edge. The full-grown leaves resemble the stunted, toothless leaves of M. caninum exceedingly." This description exactly accords with Bijlia cana. and as M. canum was discovered by Masson, who certainly collected in Prince Albert Division, it may even have been found by him in the same general locality as that from which Mrs. Tugwell and Mrs. van der Bijl obtained it.

Mrs. Bolus has placed the plant under the genus Hereroa, to which it bears no resemblance. And Schwantes, apparently without having seen the plant, first places it in the genus Juttadinteria, where it does not belong, and after I had already published the genus Bijlia, founded the genus Bolusanthemum for its reception, possibly unaware that there is already a well-known genus called Bolusanthus, with which it would probably be confused. And later, in *Die Gartenwelt*, 1928, p. 644, he appears to want to chop the poor plant in half and call each half a different species, since he states that the plant I have described is not the same as that Mrs. Bolus has described and figured as M. Tugwelliae! A view that no one who has seen the plant is likely to endorse. *N. E. Brown.*

(*To be contiuued*).

THE GENUS PRIMULA.

(*Continued from p.* 15.)

INDOBELLA (Balf. f.). Bhutan P. (Bella.)

A BEAUTIFUL dwarf, densely tufted plant, considered to be a sub-species of P. bella, with short stolons bearing rosettes of smooth, somewhat thick, spathulate leaves about three inches long, tapering to a long, strap-shaped stalk; margins furnished with regular lobes which terminate in recurved teeth. Flower stem smooth, about half-an-inch long, bearing a solitary deep blue blossom. Corolla somewhat fleshy, about three-quarters-of-an-inch across, concave, divided into five broadly wedge-shaped, deeply bifid, spreading lobes; tube about a quarter-of-an-inch long, downy outside, with a dense tuft of white hairs in the throat. Flowers in July.

It grows in the Bhutan Himalayas.

Culture: As for P. bella.

INGENS (W. W. Sm.). Majestic P. (Nivales.)

A very attractive, robust perennial species with a stout rootstock emitting numerous thick roots. The rosette of smooth, pallid, somewhat thin leaves have lance-shaped or oblong-lance-shaped, blunt or pointed blades which taper to a narrowly-winged stalk, in all from ten to thirteen inches long and two inches wide; margins entire or obscurely toothed; upper surface smooth, underside sparsely sprinkled with yellow meal. Flower stem two-and-a-half to three feet tall, densely covered with yellow meal upwards, stout, erect, bearing one, or at times two, superposed umbels of many fragrant blossoms, varying from sky-blue to lavender-blue and purple, with a grey eye. Corolla nearly one-and-a-half inch across, divided into five egg-shaped or rounded, entire lobes; tube about five-eighths-of-an-inch long, funnel-shaped, with a distinct ring in the mouth. Flowers in June.

Grows in alpine meadows on the banks of streams, in Yunnan, on the Mekong-Yangtse Divide, at 14,000 to 15,000 feet above sea level.

Culture: Grow it in good, rich, fibrous loam, in a damp, half-shady spot.

INTEGRIFOLIA (Linn.). Entire-leaved P. (Auricula-Rhopsidium).

A very beautiful species from the Alps of Europe, with a rosette of narrowly elliptic or oblong, somewhat pointed or blunt, nearly stemless leaves, three-quarters- to two-and-a-half-inches long, with quite entire, non-cartilaginous margins, fringed with minute hairs; both surfaces sparsely covered with minute, colourless glands. Flower stem one-and-a-half to two-and-a-half inches tall, glandular, bearing an umbel of one to three rosy-lilac, rarely white, blossoms. Corolla broadly funnel-shaped, three-quarters-of-an-inch to one-and-a-quarter-inch across, divided into five heart-shaped, cleft lobes; tube three-eighths-of-an-inch to three-quarters-of-an-inch long, slightly longer than the calyx, cylindrical, dilated upwards, densely glandular. Introduced in 1792. Illustrated in *Journ. Roy. Hort. Soc.*, Vol. XXXIX, 1913.

Grows on the high alpine moorlands of the Pyrenees, Switzerland and Western Austria.

Culture: Good loam and peat, in a half-shady spot, should suit it. *A. W. Darnell.*

(*To be continued.*)

HOME CORRESPONDENCE.

Apple Scab.—I think Mr. Brown (Vol. LXXXIV, p. 497) will find that the trees which are comparatively free from scab are those which are on the under vigorous side. Conversely, trees that are growing vigorously are most liable to the disease. I find that I get most scab where the trees are growing freely and producing large fruits as a result of rather too much nitrogenous manure. For similar reasons, I find that trees in grass suffer less from scab than those in cultivated land. It is not unlikely that there is some hope of gaining a certain degree of immunity from this disease by means of more balanced manuring than has been the custom in the past, notably in the increased use of potash fertilisers; but definite results are not to be expected until annual dressings have been given for two or three years. With regard to spraying, I wonder whether Mr. Brown gives his first application just before flowering. I have had very much better results since I have given the first spraying at the pink bud stage instead of just after the fall of the bloom. The trees want a thoroughly good dose of Bordeaux mixture or lime-sulphur at that time. Unless one can prevent the appearance of scab on the first leaves, there is little hope of a good control; but if the leaves are healthy for a fortnight after flowering, it is an easy matter to secure a large proportion of clean fruits. I do not remember what reply I gave to Mr. Brown's note last April, and hope I have not merely repeated myself. *Market Grower.*

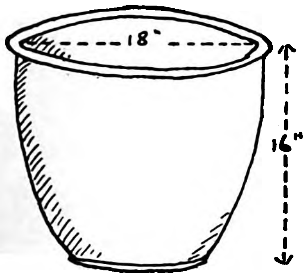

FIG. 17.—SOIL STERILISATION: THE COPPER.

Early Fruition of Fruit Trees.—In your issue for December 8, (Vol. LXXXIV, p. 456), Dr. H. E. Durham, writing of the "Early Fruition of Fruit Trees," states that on looking up the experiment of an old horticulturist, it was interesting to note a quick way of inducing seedling trees to fruit. As a boy, I remember my father experimenting on fruit trees, with the idea of accelerating their fruiting, and of dispensing with the labour of grafting as ordinarily practised in the case of Pears and Apples. This method consisted of transplanting the seedlings every year, each time cutting away the tap root, and in conjunction with liberal culture, this treatment caused the formation of fruit buds in the third or fourth year from sowing. He asserted that the labour of transplanting was far less than that involved by the raising of the necessary number of stocks and the grafting. Unfortunately, illness prevented him from continuing these experiments just as he seemed to be reaping the reward of his labours, as the trees were then very promising. As the root stock question for fruit trees seems to be receiving considerable attention at the present time, I think the above may be of some interest to anyone experimenting with fruit trees. *H. Howard Grace.*

Vegetables Under Glass.—At this time of year the Melon pits are empty and can be utilised for vegetables. Along one side come in order Rhubarb, Endive, Chicory, *i.e.*, Belgian Witloof, Chicory, excellent both in salad and braised; "Udo" (Aralia cordata), a favourite Japanese vegetable, eaten like Seakale and, finally, Seakale itself, which is, however, never so good as the Seakale bleached in the open in spring. All these vegetables are bleached by excluding light by means of Potato sacks spread over a light wooden frame. The temperature is kept round about 55° to 60°, which exactly suits the Asparagus on the other side of the pit. Asparagus is one of the most profitable vegetables to force, and the supply is merely limited by the number of crowns that can be spared. Asparagus here is always grown from seeds and pricked out, and the third year transferred to the beds, but it was only last year that I learned from Mr. F. J. Chittenden that the yield could be doubled by planting male plants only; this is a practice which obtains in America. This year we are trying two new strains: Glory of Brunswick and Scheekopf—"Snow Head," a self-blanching Asparagus. Asparagus is usually blanched by heaping sand on the crowns, but in Holland inverted pots are placed over the crowns so soon as the soil cracks. *William Lawrence, Burford.*

Soil Sterilisation.—I have read with great interest the splendid articles regarding soil sterilising in your recent issues, but being one of the "small fry," I am venturing to send you the notes of the method that I have adopted for many years past with every success. The cost of my "plant" is about one hundred pence—not £100. I have enclosed rough drawings to enable you more clearly to understand what I mean. I bought an old, rusty, but sound iron copper (Fig. 17) for 1s., which held ten gallons. The village blacksmith made me a stand or holder (Fig. 18); the ring is one-and-a-half-inch by a quarter-of-an-inch, and the three legs are one inch by three-eighths-of-an-inch. The ring is made to allow the copper to be lifted in and out easily. A piece of strong sheet iron (Fig. 19) was fitted in the bottom of the copper and it just cleared a measured gallon of water; a number of quarter-inch holes were drilled in the plate. By means of a few bricks, I make a fire-place, with the aid of an old piece of iron grating, and place some old sheet iron around the legs of the holder, leaving a space for feeding the fire. I place the apparatus in an out-of-the-way place and light a fire, using wood and coal; put a gallon of water below the grid, and fill the copper with the soil to be sterilised, being careful not to press it down. I bury a Potato two inches deep in the centre of the soil, place a piece of sheet iron on top, and keep a good fire going for forty to sixty minutes, and when the Potato is done to a turn, I lift out the copper (with some help), empty out the soil, let the copper cool a little, put in another gallon of water, and start again. In this way we do six "cookings" in a day, which gives quite a useful heap of first-class material. The soil must, of course, be neither too wet nor too dry when used.—*L. J. Moore (gardener to Col. F. E. Allfrey), Ivy Cottage, Sherington, Newport Pagnell.*

——I have read with great interest Mr. Falconer's article on sterilisation, although the subject is not new to me by any means, for it is more than twenty years since I first started sterilisation of soil, with such excellent results that I fail to understand why it has not become more generally adopted. I do not quite agree with Mr. A. Falconer that the method of steam sterilisation is the simplest, least costly and most satisfactory. Everyone is not so fortunately situated as to be able to draw steam from an existing boiler. To erect a thorough steam steriliser for a large establishment would cost a hundred pounds, and that in itself debars its general use. In my humble opinion steaming is too complicated to become general, whereas nothing could be more simple than baking, as a garden boy can manage this job. If Mr. A. Falconer will refer to *The Gardeners' Chronicle* of November 5, 1927, he will find a brief note on soil sterilisation. We sterilised everything used for potting purposes—leaf-soil and manure. Our garden boy got quite an expert at the job, and he frequently asked the foreman if he wanted any soil baked! *John Butler, Rose Cottage, Kidlington.*

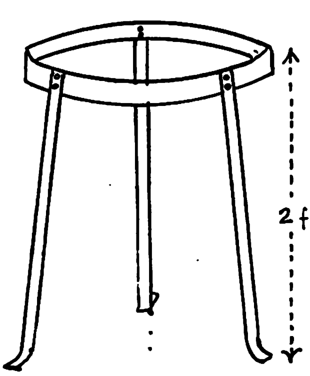

FIG. 18.—SOIL STERILISATION: THE STAND.

Eomecon chionantha.—It would appear, from Sir William Lawrence's interesting letter in your issue of December 18, 1928 (p. 478), that unwittingly in writing of this plant (p. 428), I conveyed the impression that the English equivalent of "Poppy of the Dawn" should be substituted for the Greek Eomecon. This was not my intention, as no one is more aware of the disadvantages involved in using English names for plants than the writer. To those of us who know a little Greek a name such as this presents no difficulty, but, as one coming in contact with many amateurs and gardeners without even a rudimentary knowledge of that language, I find that words from the Greek appear to present greater obstacles than those from the Latin. I know that "Eomecon chionantha," easy to some of us, is a pitfall for a goodly number of flower-lovers, hence my remark, which I did not intend to imply that I preferred the English equivalent. Writing, as I did, from a gardening point of view, I wanted to stress the point that this botanical name prevents the plant in question from being appreciated by the many. I am in entire accord with Sir William Lawrence's plea for simpler nomenclature, and hope the forthcoming Conference will do something to make things easier for the many who love their flowers, but whose lack of knowledge of Latin or Greek prevents them from the full enjoyment of their flowers and gardens. *S. Arnott.*

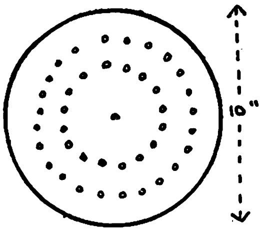

FIG. 19.—SOIL STERILISATION: THE GRID.

Buddleia Davidii v. B. variabilis.—From what I can see of it, B. variabilis var. Veitchiana, sent out as a novelty by the firm of Messrs. J. Veitch and Sons in 1903, could not be considered as the type, B. Davidii of Franchet, seeing that the latter was described in 1887 (see Vol. LXXXIV, pp. 456 and 496). In a live state, it was introduced from St. Petersburg about that time, but it was a very poor, semi-prostrate form not worth cultivating. The variety Veitchiana was not collected until 1901, and both that and the variety magnifica are infinitely superior to the original introduction. B. variabilis was described by W. B. Hemsley from seven specimens collected by Dr. Henry in 1887, or about that time, and from a specimen collected by Faber. These specimens represented some very extreme forms in the matter of foliage, but they were connected by intermediate gradations. The description of B. variabilis was published partly in 1889 and partly in 1890. As this Buddleia has been planted far and wide it will not be easy to change the name now. *J. Fraser.*

Apple Ribston Pippin.—There is a note in your issue of December 15, 1928, referring to the original tree of this Apple, and in that note your correspondent (*E. C. M., Streetly, Staffs.*), remarks, *inter alia*, that he has heard, with some authority, that Ribston Pippin comes true from seeds. I should like to know exactly what he means by this. Does he mean that it always comes true from seeds, that it occasionally comes true, or that it is fertile to its own pollen? And, further, it would be interesting to know from whose authority he makes the statement. In the case of my recent introduction, Saltcote Pippin, this fruit, although a seedling from Ribston Pippin, bears little resemblance to the seed-parent, although there are certain traces.

Unfortunately, its pollen-parent is not known, but most of the experts who have inspected it find evidence of Cox's Orange Pippin, both in its appearance and flavour. I have never bred with Ribston Pippin myself; it would be of much interest if any of your readers who have done so would give us some information bearing on the remarks of your correspondent. *F. Herbert Chapman, Rye.*

VEGETABLE GARDEN.

ONIONS.

THE arrival of the new seed catalogues reminds one that the time has come for preparation for seed-sowing, and one of the first vegetables to be considered is the Onion, especially if required for exhibition purposes. It is unnecessary to state that only the best seeds of the best varieties are any good for this purpose, and, indeed, the best seeds for all kinds of vegetables are not only more reliable, but cheaper in the end. Therefore, procure your seeds from a reliable source, and sow them so early in the New Year as possible. To obtain fine Onions that will keep well, a long season of growth is necessary, and this is especially essential in the northern half of the country, and where the soil is cold and heavy.

In preparation for sowing the seeds, some clean pans or boxes should be crocked carefully, some rough material being placed over the crocks to facilitate good drainage. Prepare a compost of two parts loam, one part leaf-soil, half-a-part old Mushroom bed manure, and half-a-part coarse sand, and sift the whole through a quarter-inch-mesh sieve. Thoroughly mix it, and then fill the pans or boxes to the surface, making it firm. Carefully select the best seeds and sow them thinly, covering them with about an eighth-of-an-inch of soil, and pressing the surface down fairly firmly. Water them with a fine-rosed can, cover with a piece of glass and paper, and place them in a temperature of 60°.

The young seedlings should soon appear, when the glass may be removed, and the receptacles placed on a shelf as near the roof-glass as possible. So soon as the seedlings are large enough to handle, they should be given a shift. Some growers prefer boxes about fifteen inches long, a foot wide, and four inches deep, and these are excellent because they may be moved about easily. The soil for this transference may be the same as advised for the seed-sowing, only sifted through a coarser sieve, and a little fine bone-meal added may be of benefit. The boxes should be clean and crocked carefully and some rough leaves or turf placed over the crocks. Fill them nearly full with soil, which should be made fairly firm, and then carefully lift the young plants from the seed pans and prick them out about two inches apart. The roots of these young Onions are very long, and great care should be taken not to break them. I am convinced that a great deal of the after success with Onions is due to careful pricking out, as the plants commence growth so much quicker if the roots at this stage are not damaged. When all are pricked out, water them in and place them in a vinery or Peach-house in which the vines or trees have been started into growth, and place them as near the roof-glass as possible. Take care not to over-water them, but rather give them a syringing overhead with tepid water, especially on bright days. Under such conditions they should make rapid progress and soon be ready to move into a slightly heated frame, where they may be given fresh air as the weather allows, guarding, however, against cold winds. Keep the surface soil stirred with a pointed stick, and apply water only when necessary. As time goes on, and the young plants become stronger, they may be removed to a cold frame and gradually hardened off, ready for planting out.

Another excellent method, and one which I tried last season, is to prick the seedlings straight out into a frame having a three-inch hot water pipe running all round. About three or four inches of prepared soil was placed on a bed of coal ashes, and made very firm; when finished, the surface of the bed was about six inches from the glass. The seedlings were then carefully pricked out about three inches apart, and well watered in. For the first fortnight or so the plants were syringed overhead in the early afternoon, and the frame kept closed. The soil was occasionally stirred and more air was admitted as the weather conditions allowed. As spring advanced, the lights were removed during warm days. Under this treatment it was found that the plants made remarkable progress. I was able to lift each plant with a good ball of soil, and they all grew away freely directly they were planted out.

Regarding the site for the Onion beds, it should always be in an open, sunny position, and should, if possible, be trenched, or double dug before the old year is out. A good dressing of well-decayed farmyard manure should be dug in both the bottom and top spit, and thoroughly well mixed with the soil. If one has time to trench the site, any decaying garden refuse may be placed in the bottom of each trench, and if the soil is heavy, the rougher the material incorporated the better, as this will tend to keep the soil open and provide drainage. The Onion resents a stagnant soil, and good specimens cannot be secured unless the ground is well prepared. Leave the surface as rough as possible and, when the plot is finished, give it a good dusting with soot. The winter rains will wash this in, to the ultimate great benefit of the plants. Some time early in March, when the surface is fairly dry, fork the bed well. The drying winds usually experienced at that period help to break the surface soil up ready for raking over in preparation for planting. About the first or second week in April is a good time for this latter operation, provided the weather is not wet.

The bed should be trodden well to make it firm if the surface is dry and friable, and then raked over with a small iron rake until a fine tilth has been produced. Procure some long boards and place them in a row up one side of the bed. At a convenient distance in front of this stretch a garden line from end to end, and all is ready for planting. The plants will by then have been hardened off, and should be sturdy and strong. Lift each one carefully from the box or frame, securing as much soil as possible with each, and plant them with a trowel, taking care to make a hole large enough for each ball of soil to fit in without cramping. Press each one in firmly so that the base of the plant is slightly below the surface, or just deep enough to keep it upright. It is a great mistake to plant Onions too deeply. Rake the ground neatly after each row is planted and, when the whole is finished, lightly water the plants in with a rosed can—better still, water every three or four rows as the work proceeds, as it is better not to tread on the bed more than is necessary. About a foot or fifteen inches apart is a very good distance at which to plant Onions, both in the rows and between the plants, and if the bed is a wide one, a path should be left up the middle by missing a row, thus making it much easier to get at the plants for watering and other cultural operations. If the weather should prove showery at this time no other attention is necessary, beyond hoeing the bed occasionally with the Dutch hoe to keep the surface open. If the ground has been well prepared, as advised, there should be no necessity for very heavy watering, especially if the summer proves a moist one. If, however, the weather is hot and dry, the plants should benefit greatly from good soakings of water, and a daily syringing overhead, preferably during the afternoon in time for the foliage to become dry before night. Soft water, or that which has been exposed to the sun, is the best to use; on no account use cold water from a main supply or well, as this will encourage attacks of mildew. An occasional watering with diluted liquid manure, and during showery weather a dusting around each bulb with some approved fertiliser, should help to produce fine bulbs, but, on the other hand, over-feeding should be guarded against, or the bulbs will become thick-necked, and will also not keep well. Frequent hoeings between the rows are advisable to preserve a friable, open surface, and also to keep weeds in check.

The bulbs should be carefully gone over as they attain size, and any loose skin removed. So soon as the bulbs have finished growing in the autumn, the tops may be bent over, doing two rows at a time, and turning the tops inwards, and after awhile the bulbs may be lifted with a fork and allowed to remain for a few days with the soil attached. In three or four days' time remove the soil and trim the roots off with a sharp knife; if the tops are sufficiently ripe, take these off also. Place the bulbs on an open staging in a cool house or frame where they may ripen thoroughly before being stored. They should be handled carefully at all times, or they will be bruised and so rendered useless.

Onions for kitchen and other uses are best grown on firm, good soil which has been well dug and manured. A good plan is to sow the seeds thinly in shallow drills, in a frame placed on an old hot-bed, in some good, friable soil. Keep the frame closed after watering the seeds in, and cover it with some light material until germination takes place, then gradually admit air and light as the weather permits. So soon as the plants are large enough to handle they may be planted out carefully in rows about one foot apart, allowing six inches between the plants. Water them in well if dry weather prevails, and during their season of growth keep the bed well hoed. Dust the beds occasionally with old soot, preferably during showery weather. Care should be taken to ripen the Onions properly, after which they should be stored in a dry and frost-proof shed, on open shelves, so that air can circulate freely among them.

Winter Onions are really autumn-sown Onions, which stand out-of-doors all the winter, hence the name. Seeds should be sown in a warm border in August, in ground that has done duty for early Potatos. This should be made firm, and the seeds sown in drills one foot apart. They should soon germinate and, when the seedlings are well through the soil, they should be dusted with some old soot, and the ground between them stirred with the hoe. The stronger the plants, the better will they withstand severe weather. A little rough leaf-soil strewn about them should help them to come safely through severe frosts, and in March they should be planted out one foot apart on well prepared ground and, if required for early shows, should be fed liberally and kept clean.

Pickling Onions may be sown during April on any good ground, in drills about six inches apart, the seedlings being thinned out to give them room to develop. Small, firm bulbs are the best for this purpose. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

THE MARKING OF IMPORTED ROSE TREES.

AN application was recently made by the Horticultural Trades' Association and the British Rose Growers' Association to the Standing Committee appointed under the Merchandise Marks Act, 1926, for Agricultural and Horticultural Produce, asking for an Order in Council that each imported Rose tree should be marked, both at the time of importation and when exposed for sale and sold, by means of a lead or zinc label, stamped with the indication of origin and attached to the "collar" of the Rose tree. It was expressly requested that Rose stocks should be excluded from the scope of the Order.

The applicants were represented on the enquiry by Counsel, Mr. C. G. L. Du Cann, instructed by Messrs. Ralph Bond, Veitch and Bilney, the solicitors for both the Associations. Evidence was given in support by Messrs. Courtney Page, Cutbush, Merryweather, Cook, Murrell, McGredy and Paton. It was stated on behalf of the applicants that no separate statistics of imports of Rose trees into the United Kingdom are available, but that the imports are estimated to amount to approximately 4,000,000 trees per annum. Practically all of these are imported from near European countries.

The Committees have now made their report, in which they state that these imported trees are, as a rule, less suited to the conditions of this country than those which are raised at home; that the ordinary purchaser, in that absence of marking, would not be able to distinguish between home-grown and imported Rose trees, although an expert generally would be able to do so; and that, as it is already a common practice to label Rose trees at some stage before reaching the ultimate purchaser with the name of the variety, a requirement of marking with an indication of origin would involve but little additional trouble or expense.

The Committee were informed on behalf of the retailers that they would not object to a marking Order, provided the marking of each individual tree was required on importation, so that retailers would be called upon only to continue the indication of origin which had been applied before the trees came into their hands.

The Committee add that after hearing the evidence, they are of opinion that there are no special circumstances which would render necessary an Order for marking on importation, as distinct from an Order for marking on exposure for sale and on sale. On the whole, however, they think there may be some advantage in requiring marking on exposure for sale wholesale, as well as at subsequent stages. It is possible, if not probable, that the effect of requiring marking on exposure for sale and on sale wholesale, as well as on exposure for sale and on sale by retail, will be that arrangements will be made within the trade for the marking to be done before the trees are exported from the country in which they are grown.

The Committee have accordingly recommended that an Order in Council should be made prohibiting the sale or exposure for sale, wholesale or by retail, in the United Kingdom, of imported Rose trees, unless each imported Rose tree bears an indication of origin. The Order should state that it does not extend to Rose stocks.

As regards the form and manner of applying the indication of origin, they recommend that the indication of origin should be legibly and durably marked either (1) on a metal or wooden label securely attached by wire or other metal fastening to the collar of each Rose tree; or (2) on a metal band clasped round the collar of each Rose tree. Section 10 (1) of the Act prescribes the indication of origin to be given in each case, and provides that the indication shall be conspicuous.

The report states that the Committee see no reason to delay the operation of an Order in Council beyond the period prescribed in Section 2 (8) (b) of the Act, and accordingly suggest that the Order should come into force three months after it is made.

It is very satisfactory that the efforts of the Horticultural Trades' Association and the British Rose Growers' Association for the protection, not only of British Rose Growers, but also of the public as purchasers of Rose trees, should have met with such gratifying results.

LAW NOTES.

FRAUDS ON NURSERY FIRMS.

BEFORE the Horsham Bench, at Horsham Town Hall, on December 28, 1928, a man who had given the name of Thomas Arthur Moore, but whose real name was stated to be Douglas Ludwig Fardoe, was charged on remand with obtaining, by means of fraud other than false pretences and contrary to Section 13 (1) of the Debtor's Act, 1869. The firms so imposed upon were Messrs. Wheatcroft Bros., Gelding, Notts., to the amount of 40s.; Messrs. David Fleeman and Son, Scorton, Darlington, to the sum of £2 17s. 6d.; and Messrs. L. A. Chamberlain, South Wigston, nr. Leicester, on three separate occasions, to the total amount of £6 7s. 6d. The prisoner pleaded guilty to all the offences.

Mr. C. G. L. Du Cann (instructed by Messrs. Ralph Bond, Veitch and Bilney) prosecuted.

Counsel stated that the prisoner was charged with nine offences, but that he proposed to withdraw four of these as further enquiries had brought forward evidence that possibly these were committed by the prisoner's father (who was himself serving a sentence of imprisonment), and to proceed on the five charges above only.

The prisoner's frauds had been perpetrated by the defendant obtaining lodgings in various localities under false names, and in those names ordering goods from nurserymen without having the slightest intention to pay for them. The names he had used were Fox, Henderson, Thompson, Fardoe (or Phardo), Knight and Moore, and he had had addresses in Ealing, Brondesbury, the Isle of Wight, Littlehampton and Crawley, from each of which he had absconded without paying. Prisoner had given a great deal of trouble, but in the long run a warrant was obtained for his arrest, and when the officers went to execute the warrant, prisoner escaped through the bathroom of the next house. He was ultimately found, through the vigilance of Superintendent Beacher and his officers, at Merstham, in Surrey, where he was arrested. On being arrested, the prisoner made a statement which would be given in evidence. The five offences charged against the prisoner did not by any means represent the whole of the frauds, which were widespread, but the prisoner had apparently calculated that he might safely continue his practices and that individual nurserymen would not prosecute so long as they were only swindled of small sums. In the aggregate, however, the sums obtained by the prisoner from the trade were considerable, and they were obtained in many cases from small traders who could ill afford to lose them.

Mr. Harry Wheatcroft, a member of the firm of Messrs. Wheatcroft Bros., Nurserymen, of Gelding, Nottinghamshire, gave evidence that on November 11, 1928, his firm received a communication signed "T. Moore," containing an order for twelve standard Rose trees and promising remittance on receipt of the goods. The goods were despatched and receipt was acknowledged by prisoner, who ordered another twenty-four Rose trees at the same address. The firm's suspicions were aroused, and they caused enquiries to be made. In response to Counsel, Mr. Wheatcroft said that his firm would not have given either credit or goods had they been aware that the prisoner was using a false name.

P.C. Draper, an officer stationed at Crawley, said that, acting under instructions, he kept the residence of the prisoner under observation. On December 19, he saw a young lady leave the prisoner's house with Rose trees. He followed her. She went to Merstham, in Surrey, where she met the prisoner. The constable then arrested the prisoner and said he was going to take him back to Crawley. The prisoner said he wanted to know more about this. The warrant was read, and he was cautioned, to which he replied: "I think this firm have an audacity to take this action over such a small amount." At the Police Station, he made a further statement (which was produced) in which he said the firm had the audacity to place the matter in the hands of the Police without writing to him for the money. Superintendent Beacher stated that the Defendant, on December 20, 1928, made the following voluntary statement to him after being cautioned:—"My name is Douglas Ludwig Fardoe. I am heavily in debt, and had goods from firms but I could not pay, so I absconded. I have a mother and sister to look after, which I have been trying to do. My hope is to go to sea, and to try and get on my feet to pay my debts. This statement has been read over to me, and it is true."

At this stage of the proceedings, the prisoner intimated that he desired to plead guilty, and to be dealt with by the Magistrates, instead of being sent for trial. Counsel thereupon recalled Superintendent Beacher, who outlined the history of the prisoner, and stated that since the early part of the year 1928 he had been obtaining a livelihood chiefly by defrauding nurserymen of their goods.

The Bench, after retirement, sentenced the prisoner to twelve months imprisonment with hard labour—the maximum imprisonment for this class of offence—being four months on the first charge and two months on each of the other charges, the sentences to run consecutively. Council invited the Bench to commend the Officer in charge of the case, as, but for his vigilance and promptitude, the prisoner would have succeeded in eluding justice. The Bench instructed that its commendation should be notified to the Chief Constable.

SOCIETIES.

YORKSHIRE FLOWER SHOW AND GALA.

THE annual meeting of the above Association was held on January 1, and the arrangements for the flower show and gala in 1929 were fully discussed. It was decided to hold the next show on Tuesday, Wednesday and Thursday, June 18, 19 and 20, and every endeavour will be made to create a show of outstanding merit. The schedule of prizes is now in course of preparation, and copies will be available to all applicants to the Gala Secretary, Assembly Rooms, York, in the course of a week or ten days.

NATIONAL CHRYSANTHEMUM.

THE last meeting of the Floral Committee for 1928 was held on December 31 at the Royal Horticultural Society's Hall, Westminster, and the following awards were made.

FIRST CLASS CERTIFICATE.

New Year. V. 1. a.—A very handsome and showy Single variety, with two rows of broad, substantial florets. The colour is a very pleasing shade of orange-bronze, enhanced by the yellow zone round the disk. Shown by Mr. H. SHOESMITH, junr.

COMMENDATION.

Bronze Conquest. II. 1 b.—A Decorative spray variety of soft bronzy-yellow colour. It is a sport from Crimson Conquest. Shown by Mr. H. WOOLMAN.

The variety Rosabelle, a wide-petalled, deep purplish-rose Single variety, shown by Mr. H. SHOESMITH, junr., the Committee desired to see again.

Obituary.

Charles Dixon.—In the Victorian period, the gardens of Holland House, Kensington, were well-known to the public, as the Royal Horticultural Society held its annual show there in July for several years in succession. Hence the exhibition became known as the Holland Park Show. During these shows, many of the older generation of gardeners and nurserymen became acquainted with Mr. Charles Dixon, the venerable gardener there, who retired about ten years ago, and passed away on the 6th inst., at his residence, Oak Villa, Kent House Road, Sydenham, at the great age of ninety-five years. Mr. Dixon had a remarkable career, having been gardener at Holland House for fifty-five years. Forty years ago, the late Lady Holland left him a pension of £50 a year. Twenty years ago, the late Lord Ilchester left him another pension of £50 a year. Hence he has had two pensions for many years. At the age of eighty-two, Mr. Dixon married his second wife, who predeceased him three years ago. Mr. Dixon was for many years a member of the Floral Committee of the Royal Horticultural Society and remained so until he was ninety years of age. *W. B. G.*

ANSWERS TO CORRESPONDENTS.

FREESIA FOLIAGE MOTTLED.—*B. S.* The cause of the mottling of the foliage of the Freesias received is at present unknown. It may be safely stated that the trouble is not due to a fungus, but whether a virus is responsible or whether the trouble is due to some physiological factor, we cannot say. Work is being carried on in connection with this disease. Flowers are produced on plants bearing mottled foliage, but the plants become weakly and tend to die off by the end of the growing season. Remedial measures are unknown, but it will be a good plan to discard bulbs of plants bearing streaked foliage.

MARKETS.

COVENT GARDEN, Tuesday, January 8, 1929.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the day in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—Eds.

Remarks.—The return of colder weather has been responsible for much shorter supplies throughout this department during the past few days, and all white blooms are now increasing in value. Lilium longiflorums have suddenly become scarce, and the present prices are the highest realised for some months past. Arums (Richardias) are again back to the prices realised during Christmas week, while Carnations are limited in quantity and prices are on the up grade. The best blooms of Roses Madame Butterfly and Sylvia are from home-growers. Daffodils are gradually increasing in quantity, especially Golden Spur, several boxes of which have been received from the Spalding district. Supplies of Tulips are increasing, and they are greatly appreciated. Some good quality blooms of Narcissus Grand Primo and Soleil d'Or have arrived from Guernsey. The present weather conditions having checked the supply of single Violets, many orders could not be fulfilled this morning. White and mauve Lilac and Prunus triloba are now arriving in excellent condition.

In the French flower department supplies are likely to become much shorter during the next few days, owing to severe weather in France. Paper White Narcissi and Violets were below requirements this morning. A few blooms of Rose Ulrich Brunner are arriving from this quarter in excellent condition, while a few mixed Anemones De Caen realised 2/6 and 3/- per bunch to-day.

Remarks.—Business all round is on the quiet side, perhaps rather more so than usual for the time of year. Ample supplies of Hothouse Grapes are available, but the demand is moderately good and values are keeping firm. The increasing supplies of choice fruits from the Cape are meeting a good reception by the buyers. The principal fruits consist of Peaches, Plums and Apricots, and are in fairly good condition. The Apple market is experiencing a period of poor trade, except for large, good cooking Apples. The few English Apples that are being marketed just now sell well if of first grade, and the sprinkling of Cox's Orange Pippins are also doing moderately well.

Choice vegetables, such as Asparagus and hothouse Beans, Peas and new Potatos, are all comparatively costly. Mushrooms have improved in price, and the cold weather will be responsible for some shortage in that department. Cornwall and St. Malo are sending Cauliflowers, which are selling freely, although prices are not so high as last season. A few Cucumbers are available and are realising high prices. Lettuces from France are more plentiful and cheaper, and other salads from the same source are quoted at reasonable prices, but advices suggest a shortage towards the end of the week, owing to extreme cold weather in France. Green vegetables are slightly more expensive, but are not particularly costly. The old Potato trade remains unchanged.

GLASGOW.

The severity of the wintry spell of weather had a restricting influence on business during the past week. A large area of the country was enveloped in a dense fog for four successive days, and frost up to 16° was registered. The New Year holidays accentuated the depression, which was reflected more or less in the cut flower market. Carnations fluctuated between 2s. 6d. and 6s. per dozen, while Roses declined to about half the previous figures at 4s. to 6s.; Tulips made irregular prices, William Copeland ranging from 9d. to 2s. for 6's; Thomas Moore, 1s. to 1s. 3d.; and Couronne d'Or and Rosina, 1s. 6d. to 2s.; Golden Spur Narcissi were worth 2s. to 2s. 6d.; Richardias, 5s. to 6s.; Anemones, 2s.; Ranunculus, 1s. 6d.; Lily-of-the-Valley, 1s. 6d. to 2s.; Asparagus, 1s. to 1s. 6d. per bunch, and 2s. to 3s. for trails; and Smilax, 1s. to 1s. 6d. Supplies of Chrysanthemums continue to dwindle. Florrie King and Sunshine realised from 8d. to 1s. for 6's; white and yellow Thorpe, 1s. 6d.; Favourite and Wilcox, 1s. to 1s. 3d.; Heston White, 6d. to 1s.; Winter Cheer, 2s. 6d. for 6's and 3s. for large sprays; and Duckham, 3s.

The fruit market was very quiet, with Apples and Oranges unchanged in values. Pineapples sold at 4s. 6d. each; home-grown Grapes, 2s. 6d. to 4s. 6d. per lb.; and the first arrivals of bitter Oranges, 19s. per chest. South African Plums realised from 6s. to 10s. per box, and Peaches from 8s. to 10s. Incoming steamers with fruit cargoes were held up at the "Tail of the Bank," and in consequence there were no auction sales of Apples, Oranges, etc. Vegetables were scarce and dear. Cucumbers commanded 30s. per dozen, and Lettuce, 9s. per box of two dozen.

TRADE NOTES.

Both amateur and professional gardeners will welcome the 1929 catalogue of Messrs. Joseph Fison and Co., Ltd., of Ipswich, not only as a list of goods and prices, but as a store of practical hints and tips which will help them throughout the year. This latest edition, which has just come to hand, is interesting and helpful. An especially instructive feature is the report of two fertilisation experiments recently made at the firm's experimental station. The photographs and figures given form a convincing example of how perfectly plants (in this case Tomatos and Oats) may be controlled and developed by the correct administration of scientifically compounded plant foods. Many of our readers are familiar with the good offices of Messrs. Fisons' Technical Bureau. Help in such matters as weed identification and eradication is always useful; and this and any other kinds of assistance may be readily and gratuitously obtained from Messrs. Fisons' Bureau. A copy of this catalogue may be obtained post free from Ipswich.

Patents and Trade Marks.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers of *The Gardeners' Chronicle*.

SUPPLEMENT PLATE.
Arenaria Ledebouriana.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38·3°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, January 16, 10 a.m. Bar. 30·1. Temp. 31°. Weather, Fine.

A Garden Classic.

"OF the making of books there is no end" is especially true of books on gardening, which pour out in "damnable iteration," but a very old book on horticulture which came our way recently proved to be more entertaining than many of the moderns. It was the famous William Cobbett's *English Gardener* (1829). The *Rural Rides* of the great "reformer" is, of course, a classic, but his charm as a writer on gardening has been forgotten. Few could write English, racy of the soil, as he did, and this gift applied to gardening is welcome, for so little has been added to the art of the tiller of the soil in the last one hundred years that it is a pleasure to see the verities stated in vigorous Anglo-Saxon. The motto on the title page makes a forceful beginning, taken from the wisdom of Solomon: "I went by the . . . . vineyard of the man void of understanding, and lo! Nettles covered the face thereof: I looked upon it and received instruction," and his preface gets to the root of the matter when he states: "the reason why books on gardening are read in general with so little benefit is this, that they are often put together by men who, though they understand how to do the thing themselves, are unable to convey their instructions in language easily to be understood." That Cobbett knew "how to do things himself" there can be little doubt; it may not be known generally that he began life as a gardener and was apprenticed to Kew in his youth. In his day there was no more popular writer and speaker on rural economy. It is a merit of this book that even the simplest gardening operations are lucidly described, and one has only to read the ten pages afforded to Cucumber growing to learn that he was a master of more skilled operations. Of course, as one might expect, many of Cobbett's little mannerisms peep out at times. He was famous for his dislike of the Potato, just coming into use as a table food one hundred years ago, "as a mere vegetable or sauce (sic)" he writes, "it does very well to qualify the effects of fat meat, or to assist in the swallowing of quantities of butter." Another amusing remark is under "Purslane"—"a mischievous weed, eaten by Frenchmen and pigs when they can get nothing else." But these quotations must not be taken as typical. Except in the matter of varieties, the directions given are admirably suited to present day conditions. Nevertheless, one enjoys the writing for literary pungency rather than technical merit; for example: "I will not with Lord Bacon, praise pursuits like these, because 'God Almighty first planted a garden'; nor with Addison, because a 'garden was the habitation of our first parents before their fall'; all which is rather far-fetched, and puts one in mind of the dispute between the gardeners and the tailors, as to the antiquity of their respective callings; the former contending that the planting of the garden took place before the sewing of the Fig-leaves together; and the latter contending that there was no gardening till Adam was expelled. I like a great deal better than these writers, Sir William Temple who gave such delightful proofs of his taste in those gardens and grounds at Moor Park . . . torn about and disfigured within the last fifty years by a succession of wine-merchants, West Indians and God knows what besides." Gems of this nature are to be found all through the *English Gardener*. It is well worth the few shillings it cost on a market stall.

Our Supplement Plate.—We have pleasure in presenting as our Supplement Plate to this issue, an illustration of the dainty and charming Arenaria Ledebouriana, a plant which will appeal to all lovers of alpine plants, and especially to those in quest of the more uncommon sorts. For planting in sunny positions among rocks, in light and well-drained soil, A. Ledebouriana is ideal, for it forms a close hummock of rosettes of narrow, small, bluish-grey leaves, crowned during early summer with numerous dainty sprays of small, star-like blooms. Hailing from the Levantine Alps, where it is not uncommon, this Arenaria responds well to cultivation, and, especially in warm seasons, repays its inclusion in a collection by blossoming abundantly.

R.H.S. Medal and Cup Awards.—The Council of the Royal Horticultural Society, at its meeting on December 11, 1928, awarded the following Medals and Cups:—"Victoria Medal of Honour" (for British horticulturists resident in the United Kingdom deserving special honour at the hands of the Society), to Mr. Alexander Malcolm, the well-known amateur raiser of Sweet Peas, and to Mr. W. Atkinson, the Managing Director of the renowned nurseries of Messrs. Fisher, Son and Sibray, of Sheffield; "The Lawrence Medal" (for the best exhibit shown to the Society during the year), to the Hon. Vicary Gibbs, for his exhibit of vegetables on October 9, 1928; "Veitch Memorial Medals" and Prizes (for those who have helped the advancement and improvement of the science and practice of horticulture)—to Miss Gertrude Jekyll, V.M.H., a Gold Medal and £50, in commemoration of her services to horticulture and gardening; to Mr. C. G. A. Nix, V.M.H., a Gold Medal for his services to the Society; to Mr. John Fraser, F.L.S., V.M.H., a Silver Medal and £50, for his work on Pelargoniums, Salix and Mentha; to Mr. Samuel Smith, The Gardens, Pengerrick, Falmouth, a Silver Medal, for his work in hybridising Rhododendrons; and to Mr. W. Reynolds-Stephens, P.R.B.S., a Silver Medal, for his work in connection with the Sculpture Section of the International Exhibition of Garden Design, on October 17-24, 1928. "The Cory Cup" (for the best new hardy plant of garden origin shown to the Society for the first time during the current year), was awarded to Mr. F. C. Stern, for his Rosa highdownensis, which was shown on September 11, 1928; and "The Loder Rhododendron Cup" (for not merely floral display but the value to horticulture of the work of the recipient, whether such work includes the production of flowers or not), to Professor Wright Smith, M.A., F.L.S., V.M.H., of Edinburgh, in recognition of his very valuable work on Rhododendrons and Azaleas. "The George Moore Medal" (for the best new Cypripedium shown to the Society during the year), was awarded to Mr. R. Paterson, for Cypripedium W. H. Moore, Stonehurst variety, shown on November 27, 1928; "The Sander Medal" (for the best new greenhouse plant shown to the Society during the year), to Baron Bruno Schröder, for Amaryllis Baroness Schröder, which was shown on April 24, 1928; and "The Williams Memorial Medal" (for a group of plants of one genus which shows excellence in cultivation—fruits and vegetables excepted), to Lady Aberconway and the Hon. H. D. McLaren, for their exhibit of Primulas staged at Chelsea, 1928; and to Messrs. Sutton and Sons, for their exhibit of Cyclamens staged on February 28, 1928. These cups and medals will be presented at the Annual General Meeting of the Society on Tuesday, February 26, at 3 p.m.

The Black Currant Mite (Norfolk) Order of 1928.—The Minister of Agriculture and Fisheries, by virtue and in exercise of the powers vested in him under the Destructive Insects and Pests Acts, 1877 to 1927, has issued an Order declaring the destruction of Black Currant bushes infested with big bud compulsory in the Administrative County of Norfolk (excluding the Borough of King's Lynn, or the County Borough of Great Yarmouth). The Order came into force on the 1st inst.

Legacies to Gardeners.—The late Mr. Robert Edward Free, of The Elms, Mistley, Essex, who died on September 7, 1928, left £400 and his dogs to his gardener, Mr. H. C. Williams, if still in his employ.—The late Mr. John Farmer Thirlby, V.D., J.P., of Beechwood, Darley Abbey, Derby, who died on September 2, 1928, left £50 to his former gardener, Mr. John Kerry.—The late Lt.-Col. Richard Hammett Kirkwood, late of the Devonshire Regiment, of Boldrewood, Burghfield, Berkshire, who died on September 23, 1928, left £50 to his gardener, Mr. Walter Percy Ford.

Belgium's Favourite Rose.—The votes of 3,876 wireless users in Belgium have been cast in favour of Madame Edouard Herriot as being the best Rose. The next highest numbers of votes were given to Caroline Testout, Reine des Neiges, Souvenir de Georges Pernet, Louise-Catherine Breslau, Souvenir de Claudius Pernet, Etoile de Hollande, Madame Abel Chatenay, Golden Emblem and Elvira Arramayo. It is surprising to find a white Rose so near the head of the list; and it is unlikely that a list of Roses obtained in a similar way in this country would yield the same results.

Horticultural Club.—A Club Dinner will be held on Tuesday, January 29, at St. Ermin's Hotel, Caxton Street, Westminster, at 6.30 p.m. for 7 p.m. Following the dinner, Mr. William Hales, F.L.S., Curator of Chelsea Physic Garden, will deliver an address, illustrated by lantern slides, on "A Tour to Ceylon, Malay and Java." Members of the Club are asked to realise that a subscription of 10s. 6d.—a temporary arrangement—is insufficient to meet the rental of the Club room and other expenses; therefore, the Committee has decided that Rule 6, which reads: "The Annual Subscription for members shall be one guinea. All subscriptions shall be due and payable on the first day of January in each year" must again become operative as from January 1, 1929. Subscriptions for the current year should be sent to the Hon. Treasurer, Mr. Peter R. Barr, 11 and 12, King Street, Covent Garden, London, W.C.2.

Horticultural Show at Zutphen.—A winter horticultural exhibition was held at Zutphen, in Holland, on December 19 and 20. The weather was severe, and snow lay on the ground; but this made the contrast all the more striking between conditions outside the exhibition hall and the blaze of colour presented by the masses of flowering plants inside, music and the pleasant warmth of the atmosphere all assisting to create a cheerful impression. Tulips, Cyclamens, Primulas, all sorts of foliage plants, and great quantities of Mistleto, in preparation for Christmas, were well displayed, and the exhibition resulted in a well-merited triumph for organisers and exhibitors alike.

Miss Ellen Willmott, V.M.H.—We learn that the action brought by Miss Ellen Willmott, V.M.H., of Warley Place, Great Warley, against Galeries Lafayette, Ltd., in which she claimed damages for alleged false imprisonment and malicious prosecution, was settled in the King's Bench Division a few days ago. In February last, the defendants charged Miss Willmott with theft, and she was acquitted. The defendants have apologised to Miss Willmott and undertaken to defray her out-of-pocket expenses; and Miss Willmott has withdrawn any allegation that they were actuated by malice, and accepted their assurance that the measures taken by them were the result of a genuine mistake in connection with their efforts to prevent pilfering.

Distribution of Seeds from Kew.—A list of the seeds of hardy herbaceous plants, and of hardy trees and shrubs, which are available only for exchange with other botanic gardens, as well as with regular correspondents of Kew, is now obtainable from the Royal Botanic Gardens, Kew.

Lord Bledisloe.—Owing to various developments which have taken place in connection with the fertiliser interests of Imperial Chemical Industries Limited (particularly the formation of Scottish Agricultural Industries Limited), and to the inauguration by the Government of the Agricultural Credits Scheme, the project which the Company had in mind for the inauguration and support of a special Imperial Grassland Association has proved unnecessary and incapable of complete realisation without duplication and overlapping of effort. Lord Bledisloe, who had been invited to become the chief of this new organisation (and who, it will be remembered, relinquished his membership of the Government with that object in view) has retired from his association with the project. While regretting this step, and acknowledging Lord Bledisloe's willingness and ability to undertake the work which would have been entailed had the scheme been proceeded with, Imperial Chemical Industries Limited realised, in view of the developments which have taken place, that it had no alternative but to release Lord Bledisloe. The Company is glad to announce, however, that it has obtained Lord Bledisloe's consent to a continuance of his assistance in an advisory and consultative capacity on agricultural questions generally.

Picture Postcards of British Trees.—An interesting and instructional series of picture postcards, depicting various British trees, each as it appears in summer and in winter, together with coloured illustrations of the shoots, foliage, flowers and fruits, is being issued by the Trustees of the British Museum. The postcards so far received depict the Sycamore, Horse Chestnut, Wild Apple, Ash, Beech and Sweet Chestnut. It is stated that in these series of cards the term "British" has not received too rigid an interpretation, as it has been thought proper to include within their scope various well-known and common trees which are, strictly speaking, not native; instances of such are the Horse Chestnut and Larch. Persons desirous of obtaining more complete information than is in the leaflets describing each tree, are advised to consult the following works:—*Trees of Great Britain and Ireland*, Elwes and Henry; *Trees and their Life-histories*, Percy Groom; *Familiar Trees*, Boulger; and *Wayside and Woodland Trees* (a pocket guide), Step; while if information is required about timber, the book recommended is *The Timbers of Commerce and Their Identification*, by Stone.

MR. JOHN WOOLMAN.

Mr. John Woolman.—Commencing his horticultural career some twenty-five years ago, at his father's nursery at Tyseley, which at that time consisted only of six small glasshouses for the growing of Chrysanthemums, Dahlias and bedding plants, Mr. John Woolman has since realised his early ambition to become an active force in the horticultural world, so much so, that the name of Woolman is now a household word among lovers of Chrysanthemums and Dahlias, especially, for exhibits of these subjects, also of Carnations, by Mr. Woolman, are often among the finest displays to be seen at the leading flower shows, while the many fine novelties introduced by Mr. Woolman during recent years bear eloquent testimony to his skill as a hybridist. Mr. Woolman recalls how that when he commenced work at the Tyseley nursery, the only form of transport for exhibition material was a handcart, on which were taken Chrysanthemums and Dahlias to shows not too far distant. This method of transit soon proved inadequate, as also did the nursery at Tyseley, and a move was made to the present well-known Sandy Hill Nursery, at Shirley, over twenty years ago. In course of time, the exhibits from Sandy Hill Nursery became more numerous, many large shows were visited, and numerous successes gained. Then came the war, with its consequent disorganisation of business, and Mr. Woolman, answering the national call to arms, joined the Royal Navy. Nearly three years were spent in monitors on the Belgian coast and in destroyers bent on the destruction of enemy submarines, and he was eventually discharged after many exciting experiences. Upon arrival home, he commenced to develop a collection of border Carnations which, together with Chrysanthemums and Dahlias, were exhibited on a large scale with great success, and many trophies, gold medals and prizes were awarded each year to the Shirley displays. At the present time, great quantities of these plants are disposed of annually from Shirley, not only in the British Isles, but to all parts of the world. Despite the calls of business, Mr. Woolman finds time to serve on the committees of various horticultural societies throughout the country; the National Chrysanthemum and National Dahlia Societies are of special interest to him, and of these there is no keener supporter. Novelties of Chrysanthemums, Dahlias and Carnations are introduced each year, and the numerous awards received by them testify to their merit. From the modest commencement made by his father forty-six years ago, has been built the now extensive nursery business—with twenty-six glasshouses at its command, and conducted under the name of H. Woolman—chiefly through the ability and perseverence of Mr. John Woolman.

A German Rosarium.—The Rosery established at Sangerhausen by the German Rose-lovers' Society twenty-five years ago is now well established, and contains 250,000 Rose trees comprising 8,000 varieties. The original intention of the founders to preserve the old, favourite varieties is being fully carried out, but, besides this, the Rosery provides an opportunity, by means of a permanent exhibition, for raisers to show their novelties. The collection of wild Roses entitles this Rosery to a position comparable to that of L'Hay, near Paris, among Rose gardens.

Proposed Extensions of Covent Garden Market.—We understand that the Covent Garden Properties Co., Ltd., the present proprietors of Covent Garden Market, London, have decided on the early demolition of the old Covent Garden Opera House, which is part of their property, in order to provide for a badly-needed extension of the actual market area. The site of the Opera House will probably be utilised as an extension of the foreign fruit market, at present accommodated in a building known as the "Floral Hall," which has never been used as a flower market, although built originally for that purpose. It is also proposed to remove the present Foreign Flower Market westward, to use this area as a roadway, as formerly, the approaches to the market being seriously and increasingly congested. The inward tonnage of produce to Covent Garden in 1910 was 359,537, but in 1928 it was over a million. The time has arrived when some drastic step must be taken to increase the accommodation, and the old Opera House has to go. It was built first in 1733 and re-built sixty years later, but was destroyed by fire in 1808, this third structure being also burnt to the ground after a ball in 1856. The present building, designed especially for Italian opera, was opened in 1858, the "Floral Hall" being sometimes utilised for promenade concerts.

Association of Economic Biologists. — The Annual General Meeting of this Association will be held on January 25, at 5 p.m., in the Botany Lecture Room of the Imperial College of Science and Technology, South Kensington, London, S.W.7. Following the general business, such as the presentation of reports, election of new members and election of officers, Mr. S. G. Tallents, C.B., C.B.E., Secretary of the Empire Marketing Board, will read an address on "The Work of the Empire Marketing Board." Students of Biology and others interested are cordially invited. The annual dinner of the Association will be held at 7 p.m. in the Imperial College Union.

1928 Register of Growers of Certified Stocks of Potatos.—During the past season, Inspectors of the Ministry of Agriculture have examined nearly 9,000 acres of growing crops of Potatos with a view to certification as found to be true to type and reasonably free from rogues. Particulars of crops certified as reaching the required standard of purity, of not less than 99·5 per cent., are given in the *Register* of Growers of Certified Stocks of Potatos in 1928, which has just been issued by the Ministry. Growers are reminded that, under the Wart Disease of Potatos Order of 1923, the only tubers that may be planted in land on which Wart Disease has occurred at any time, are Potatos of approved immune varieties which have been inspected while growing, and certified as true to type and reasonably free from rogues, or Potatos of approved immune varieties saved from crops grown on the land in the previous year. The Order further provides that, on the sale of any

Potatos for planting, the number of the relative certificate issued under the Order must be quoted. In the case of Potatos of approved immune varieties, the certificate number to be quoted is that given in the *Register* of Growers, but in the case of other varieties, the number to be quoted is that of the relative Clean Land Certificate issued to the growers concerned, and not that of the Purity Certificate quoted in the *Register*. Copies of the *Register* of Growers may be obtained from the Ministry on application to its Offices, 10, Whitehall Place, London, S.W.1, price 1s.

The Grading of Scottish Potatos.—This subject was discussed at a meeting of the Directors of the Scottish Chamber of Agriculture, held at Edinburgh on Thursday of last week, when the Secretary submitted a draft scheme drawn up by the Potato Standardisation Committee of the Ministry of Agriculture for applying the provisions of the Agricultural Produce (Marking and Grading) Act, 1928, to the trade in ware Potatos in England and Scotland, together with a tabular statement showing the suggested grades, etc. Mr. J. C. Henderson, Tayport, who presided, thought they should go warily about this matter, as it seemed to him that the scheme looked detrimental to the farmer. He suggested that they might see how the system was going to work in England before adopting it in Scotland. Mr. H. Miller, West Fortune, asked if it was not a scheme for the benefit of the man who handled his Potatos carefully; the other men would have to fall into line or take the consequences. Mr. F. S. Mollison, Broughty-Ferry, expressed the opinion that they had plenty of restrictions in the Potato trade already, without supporting a scheme which would hamper the trade a great deal more. Mr. George Mercer, Dalkeith, thought the desire behind the scheme was to give the man who turned out a good article something extra for his labour. The scheme was official, and by adopting it they might get their better grades of Potatos marketed in a better way; at the same time, some of the conditions in the schedule were too severe, and he suggested that the subject be submitted to a committee for consideration. Mr. J. Rodger, St. Andrews, seconded, and this became the finding of the meeting.

Shanghai Chrysanthemum Show.—Through the kindness of Mr. G. H. Rendall, the Hon. Secretary of the Shanghai Horticultural Society, we have received a large photograph (Fig. 20) showing the Chrysanthemum Show held by his Society in the Town Hall, Shanghai, on Tuesday, November 13, 1928. He informs us that the National Chrysanthemum Society's Medal was awarded to Lady Li Ching Mai for the best twenty-four Japanese Chrysanthemums in not fewer than six varieties; the regulations permitted either cut blooms or pot plants, and Lady Mai, like most other competitors, showed two dozen plants, each carrying one bloom. One of the N.C.S. Certificates was awarded to Lady Li Ching Mai for a wonderful exhibit of trained plants, every plant trained to fit into its position in the circle. It is this exhibit that appears in the centre of the picture, and it was the great feature of the Shanghai show. A second Certificate was awarded to Mr. Koo Lan Chow for the best single specimen plant in the show. All the large plants exhibited were marvels of skilful, if formal, training and good culture.

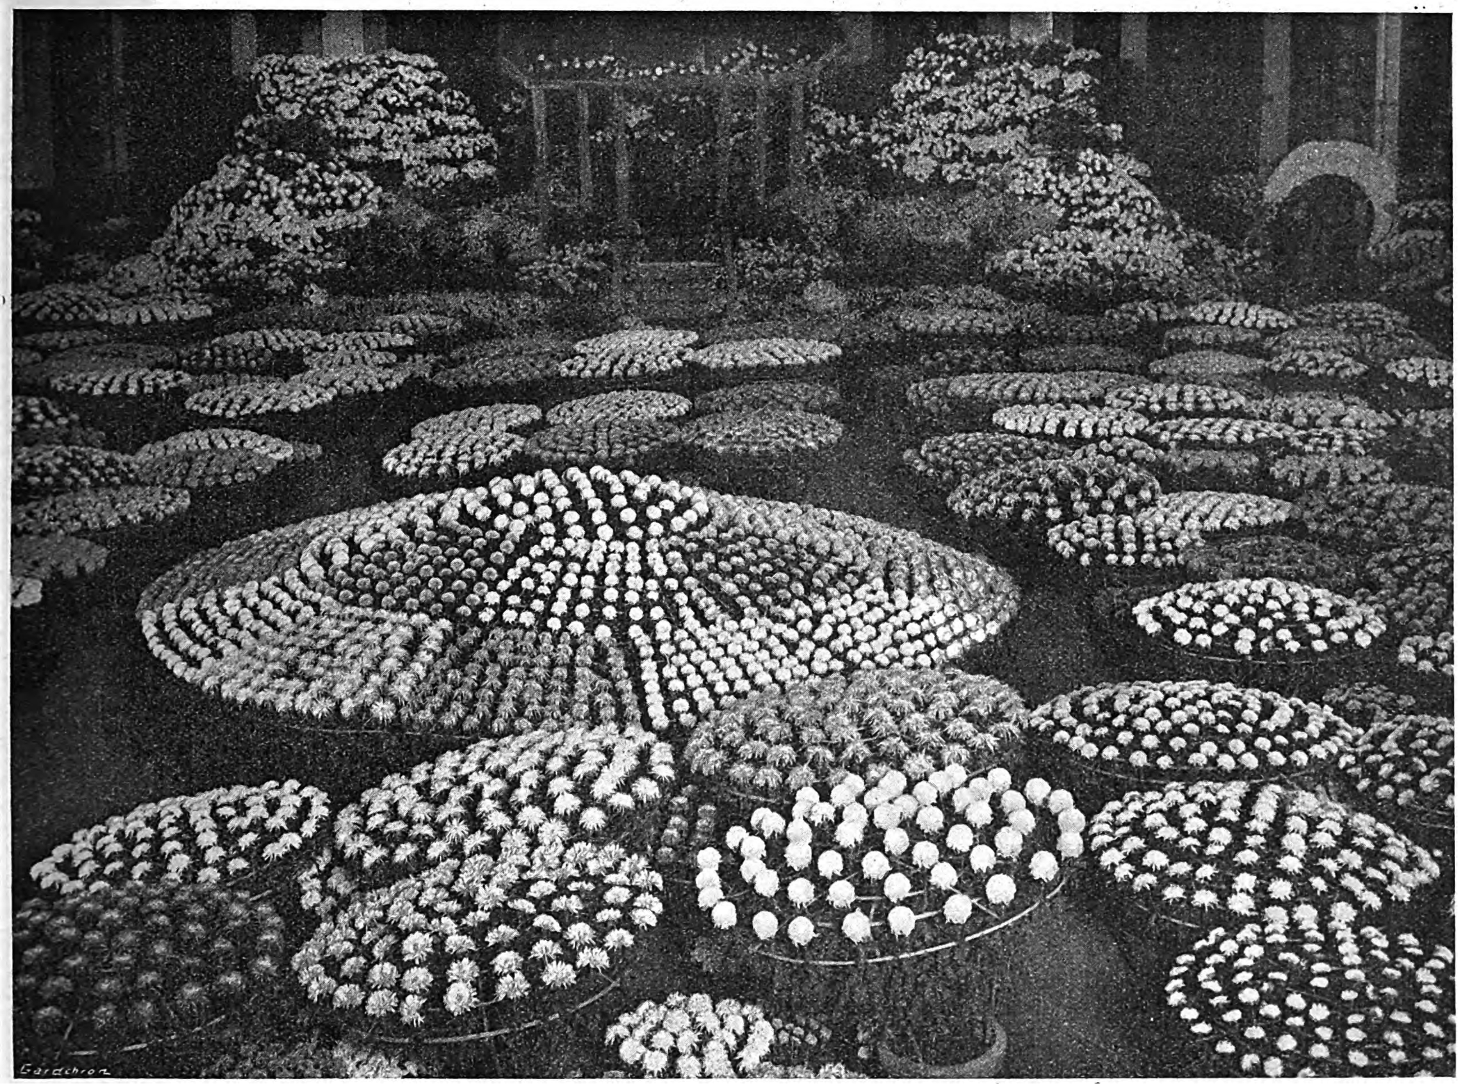

FIG. 20.—A CHRYSANTHEMUM SHOW AT SHANGHAI.

Appointments for the Ensuing Week.—MONDAY, JANUARY 21: East Anglian Institute of Agriculture lecture; Streatham Rose and Sweet Pea Society meets. WEDNESDAY, JANUARY 23: Newcastle and District Horticultural Society meets; Wimbledon and District Gardeners' Society meets; Sheffield Chrysanthemum Society meets. THURSDAY, JANUARY 24: Royal Gardeners' Benevolent Institution Annual Meeting at the Connaught Rooms.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Goldfish in Frozen Ponds.*—Are any of those good people (who are always telling you to break the ice in your ponds) aware that goldfish in China, their native place, live in rivers which are frozen over every year? One would suppose that these fishes were small whales which were obliged to come to the surface for air, which true fish, of course, never do; and the reason why you must break the ice in your ponds is that if allowed to continue freezing it lowers the temperature of the water, so that the fish are starved from cold, not want of air. If your correspondent's ponds were as deep as mine, more than four feet in every part, he might allow the ice to remain untouched in ordinary winters. I believe the fish bury themselves in the mud near the borders, and so are soon killed; but most fish-ponds are too shallow. Mine is not twenty-two feet across, and has been frozen for more than a week at a time, and I have never lost one; my chief enemies are owls. Common carp can be transported in a frozen state and thawed again alive! *Somerset. Gard. Chron., January* 21, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Miltonias.—Specimens of Miltonia vexillaria, and many of the hybrids derived from it, that have been growing steadily in the intermediate house, are now becoming more active at the roots and will require a slightly increased supply of water each time the compost becomes dry. Moisten the soil sufficiently to encourage root action, but saturation must be avoided, or the roots may decay. The outer sheath of the new growth often prevents the young roots from growing outwards; in this case the sheath should be split carefully and pulled off, so as to allow the roots to enter the compost. The young leaves in the centre of the new growth frequently adhere to each other; these should be separated with the aid of the handle of a budding knife, or a similar smooth instrument, to prevent the growth becoming deformed. Thrips should be kept in check by vapourising the division occasionally; if the pests have gained a hold, the plants should be dipped in a weak solution of an approved insecticide, tilting the plants afterwards to allow the moisture to drain away, and taking care not to allow the insecticide to reach the compost, and cause it to turn sour. The plants require a free circulation of air on all favourable occasions, but not draughts. A buoyant atmosphere should be maintained, and at this season should not be overcharged with moisture, as this may cause discoloration of the tips of the leaves, as also will overwatering at the roots. Miltonia Roezlii and M. Phalaenopsis should receive similar treatment to that prescribed above, but they require to be grown at the warm end of the house. Miltonia hybrids are very uncertain in regard to their flowering season; many plants flower twice during the year, therefore repotting has to be done at various times. The best time for this operation is when the young growths are a few inches high and about to produce new roots. Over-potting should be avoided Well-drained receptacles should be used, and a compost of equal parts Osmunda and A.1. fibre, one part Sphagnum-moss, and a few dried Oak or Beech leaves, broken up roughly and well mixed, adding crushed crocks or broken charcoal to keep it open, should make a suitable rooting medium. A little extra Sphagnum-moss may be added to the finishing layer if desired. Water should be afforded sparingly to all freshly potted plants until the new roots are well established in the fresh compost. Later on, as the sun increases in power, the plants will require shading from direct sunshine.

Coelogyne cristata and its varieties.—Where a quantity of these highly decorative Orchids is grown, their flowering season may be extended by introducing a batch of the earliest plants, which are now producing their flower spikes, into a slightly warmer temperature. They will require a gradually increased supply of water at the roots each time the compost becomes dry, care being taken not to allow the water to collect around the base of the flower scapes, or decay may set in. After the flowers are expanded, they should keep perfect for a longer period if the plants are removed to a drier and cooler position; but a moist and cool atmosphere will quickly cause the flowers to become spotted. When the flowering period is over, the plants only require an intermediate temperature, at which period also fresh rooting material may be afforded to any specimens that require it. Annual root disturbance is not advisable, and where there is plenty of room for development, top-dressing may be resorted to, carefully removing any sour soil and decayed bulbs, and working in a compost consisting of equal parts of fibre and fibrous loam, and one part Sphagnum-moss, with charcoal added to keep it open. Where repotting is necessary, three bulbs to each growing point are sufficient to retain. When remaking the specimens, some of the growing points should be arranged towards the centre of the receptacles, using small wire pegs to keep them in position. Water them sparingly until well established, while their surroundings should be kept moist by frequent syringings.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hatfield, Hertfordshire.

Flowering Plants.—The house in which plants are in bloom should always receive air through the top ventilators, both night and day, and unless the weather conditions prove unduly severe, these should never be closed tightly. On the other hand, cold draughts should be avoided. Guard against high temperatures due to excessive fire-heat, for this would result in weakened growths, and flowers produced under these conditions would lack substance. A night temperature of 50° is suitable for plants that are flowering, but on mild nights this may be exceeded to the benefit of the plants, while, on the other hand, if the nights are cold and frosty, allow the temperature to fall a few degrees rather than use too much fire-heat. Concentrated manures should be used sparingly for the next few weeks, but so soon as the days lengthen the amount applied may be increased. Soot water and diluted liquid cow manure are excellent fertilisers for these subjects.

Repotting.—Late batches of Calceolarias, Cinerarias, Clarkias, Schizanthuses, and any other annuals, that are still in small receptacles, may now be moved into larger pots. With the lengthening days, root action will be more active, and plants that are repotted now should grow quickly, the roots soon penetrating their new compost. These subjects should succeed in good, ordinary open soil. When they have filled their receptacles with roots, they should be assisted by frequent applications of liquid manure.

Wintering-flowering Begonias. — Begonias of the Gloire de Lorraine type that have passed out of flower may be cut back slightly and kept somewhat dry at the roots; but not to the extent that the production of basal shoots is checked, for these make the most suitable cuttings for producing plants for the forthcoming season. So soon as these shoots are about three inches in length, they should be removed with a sharp knife and inserted in sandy soil in a propagating frame. The other section of Begonias, represented by such fine sorts as Optima, Exquisite, Elatior, Fascination and Mrs. Heale, require careful treatment when out of flower. It is not advisable to cut these Begonias back hard, but every effort should be made to induce them to retain their foliage so long as possible. Careful watering is necessary, but at the same time, the compost should, on no account, be allowed to dry out. A suitable temperature at this season is one ranging between 50° and 60°. With careful management, most of the foliage will be retained, until such time as root action is active again. Mite, rust and fog are probably the worst enemies of these Begonias. To keep the mite and rust in check, fumigating alternately with nicotine compound and sulphur, using the latter through the Campbell Vapouriser, should be practised.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Pot Vines.—If started early last month, these should now be moving freely, and the various necessary operations should be carried out at the proper time. Disbudding and tying-in will claim first attention. Both these operations should be done with care, and a little later, each shoot should be pinched at the first or second leaf beyond the bunch, according to space. Direct syringing should be discontinued when all the buds have started, the paths, walls and borders being damped two or three times a day, according to requirements. The night temperature may be increased to 55° to 58°, with a corresponding rise during the day; a little air should be admitted on all favourable occasions. One-year-old, cut-back vines, which are intended for fruiting in pots next year, and were cut down to the lowest buds last month and dressed with styptic, may now be placed in a little heat and gradually moistened at the roots to excite growth, before being shaken out and repotted. In the meantime, clean some eleven- or twelve-inch pots, and prepare the compost in readiness for them. It is very important that the soil be prepared in advance, as all composts in which bone-meal and other concentrated stimulants are incorporated are improved by being mixed two or three weeks in advance. Good turfy loam, with lime rubble and a little bone-meal added, should make a suitable rooting medium for vines in pots. A little vine manure may be added, according to the quality of the loam. When the shoots are from one inch to three inches in length, pot the plants firmly in warm compost and plunge them in a steady bottom-heat of 75°. Syringing daily should keep them quite moist enough until new roots have formed. At this stage remove the weakest shoots and syringe and water only with tepid water; feed the vines with liquid stimulants when well established.

Peaches and Nectarines.—If a few pot trees of such varieties as Cardinal, Early Rivers, Duke of York and James Walker Peaches have been started into growth, these may now be followed by a second batch of trees, including such varieties as Peregrine Peach. Select well-rooted specimens in pots of moderate size, with short-jointed wood. Do not force them too rapidly at the beginning; a night temperature of 45° to 48° should be maintained. Encourage the trees so much as possible during the day, when sun heat is available. The chief requirements at this stage are healthy trees and well ventilated houses. Avoid a close atmosphere in mild weather, and do not allow the temperature to fall below 40° in severe weather. Early houses containing permanent Peach and Nectarine trees may now be closed, the borders well watered, and a moist atmosphere maintained not so much by direct syringing as by damping the paths and other spaces. Syringe the trees once or twice a day with tepid water in fine weather, and once only in cold or cloudy weather. As the trees approach the flowering stage, fumigate the house lightly once or twice to keep them free from aphis until the fruits are set. A night temperature of 45° to 48°, and 55° to 60° by day, with little fire-heat, should ensure a free production of blooms on healthy trees, and fruits should set freely if a temperature of 50° to 55° is maintained and the house is carefully ventilated, provided a brush is passed over the flowers each midday. As we cannot control the weather, we should endeavour to produce the required conditions in our forcing houses by maintaining a brisk, buoyant atmosphere, by supplying warmth through the pipes, and admitting plenty of fresh air.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Clematises.—Where it was neglected during autumn, Clematises of the Jackmanni, viticella and flammula types, should have last year's growths cut back, so as to force the plants to break into young growth from near the base. This treatment will not do for the lanuginosa and montana types; these only require the dead wood and any worn-out growths removed. Where it is intended to make fresh beds of these, the sites they are to occupy ought to be deeply trenched during winter or early spring. If the soil is at all heavy it will be greatly benefited by liberal applications of decayed vegetable matter, rough leaf-soil and strawy manure, which will help to keep the soil open and allow the roots to spread freely. If Clematises are to be planted in borders, dig holes four feet in diameter and at least two feet deep, breaking up the subsoil with a fork and incorporating a supply of well-decayed manure. Fill them with fresh turfy loam and decayed manure, or add a good proportion of this compost to the existing soil. As plants of Clematis are best planted from pots, they are usually easily procurable during late spring and early summer. This will be found the best time to carry out the planting, but it is advisable to prepare the sites now. When planting takes place, see that the stems are shaded sufficiently from the hottest sun. All established plants should be given a heavy mulch of well-decayed manure, applied to the surface. A corner of a wall facing south or south-west should be reserved for Clematis Armandii. This fine species, one of the best evergreen flowering climbers from western China, blooms freely at Wisley during early spring, which is a fair indication that it will give the same pleasure in most parts of the country. It is free-growing, and when happily situated will attain a height of twenty feet or more; its rich green, glossy leaves remain attractive throughout the year, while its flowers are creamy-white, changing to rose.

Roses.—Manure for mulching Rose beds next month should be prepared. If not in stock, it should be procured, stacked and turned, so that it may be in good condition for use when required. Rose species may be pruned early this month, before other work becomes pressing. The pruning of these consists of removing dead and weak wood to admit sufficient light and air into the bushes. In some varieties the long succulent shoots get killed back each winter; these may, with advantage, be shortened back.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

Pruning.—During mild weather the pruning of hardy fruit trees should be pushed on with all possible speed consistent with efficiency. Such work as digging and wheeling manure should be reserved for the early mornings, or for days when the weather is severe. There is nothing to be gained by sticking persistently to any one task, such as pruning, to the discomfort of the men employed; but when they are led by a competent foreman, and the work is varied a little, the employer stands to gain very considerably. Planting, too, may be carried out on occasions when the weather is too cold for pruning. Particular care should be taken to see that the tree roots do not become dry. This may be prevented considerably by having a plentiful supply of damp mats or pieces of sacking at hand to place over the roots while the trees await planting.

Planting.—Where this important work has been held over through inclement weather conditions, or through other pressing work, no time should now be lost in completing it. It is important that there should be ample drainage, for there is nothing more productive of canker and other kindred diseases of fruit trees than badly-drained soil. The hole for the tree should be wide and deep enough to hold the roots comfortably without crowding or cramping. All torn and injured roots should be cut back to sound wood. Place the tree in position and spread the roots to their fullest extent at their natural depths, working in about the base some of the finer surface soil, and packing it in so as to avoid air-pockets. Make the soil very firm as the filling proceeds.

Staking.—Freshly-planted fruit trees should be staked immediately, no matter how well they may have been planted, as neglect of this may seriously affect the establishment of the trees. In the case of standard trees, the best method is to place the stakes in position first, and then to plant the trees against them. This will obviate the risk of damage to the roots, as would be the case when staking is carried out after planting. Bush trees, pyramids and half-standards, however, are best supported by lean-to stakes. These stakes are driven in obliquely about two or three feet from the base of the tree, in such a way that the head of the stake is pointing in the direction from which the prevailing winds come, so as to give the tree as much support as possible. A piece of sacking should be wound around the stem of the tree to prevent the stake chafing it, and both should be secured firmly, but not too tightly, by strong tarred string.

Mulching.—Where it is possible, all newly-planted trees should have a mulching of long strawy manure to the full spread of the roots, to protect them in time of frost. When the soil is at, or near, freezing point, plant roots cease to take in water. If evaporation from the surface of the stems and branches is going on at the same time, there is nothing to repair the loss, and the tree may suffer considerably. Cold farmyard manure is not recommended for this mulching, as this tends to exclude warm atmospheric air from the roots in early spring. In the absence of stable manure the next best protection is a layer, two or three inches deep, of loose soil.

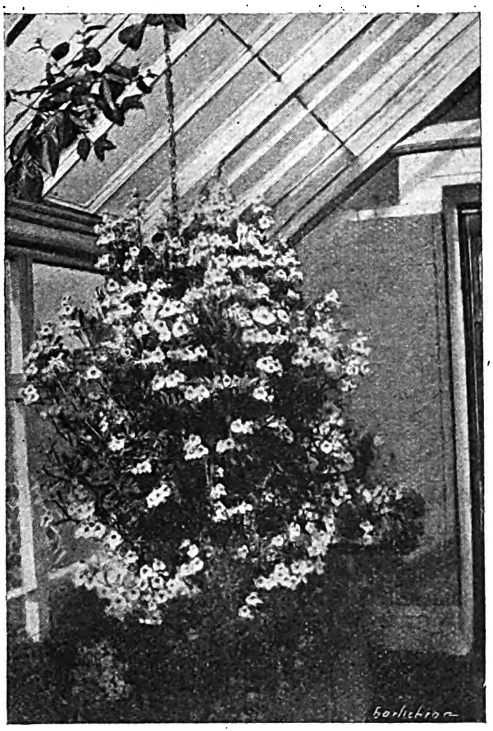

FIG. 21.—SCHIZANTHUSES IN A HANGING BASKET.
(see p. 44.)

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Vacant Ground.—Where Savoys and Broccoli have all been cut, the stumps should be dug up and removed to the rubbish heap to be burned. Manure the ground according to the crop it is to carry, and if it is not required immediately, and is on the heavy side, leave the surface so rough as possible, for the action of the weather on it will be beneficial.

Early Carrots.—A sowing of Carrot seeds should be made in frames, in drills ten inches to one foot apart. Sow the seeds thinly. When the seedlings are of suitable size, they may be thinned out, the thinnings being used for culinary purposes. Early Nantes and Scarlet Horn are suitable for this sowing.

Endive.—More plants of Batavian broad-leaved Endive may be lifted and placed in the forcing house for bleaching. If a forcing house is not available, good results may be obtained by transplanting them into frames and covering with mats to exclude the light.

Lettuce.—A sowing of Lettuce seeds should be made in pans or boxes. Sow the seeds so thinly as possible, as if they are sown too thickly the seedlings are liable to damp off. Keep the seedlings near the glass on a shelf, and water them carefully.

Bean and Pea Sticks.—The sticks for Peas and Beans should be examined and put in their various sizes, and if too few, the number should be increased. It is much better to procure sticks now, when in a dormant state, than to cut them when they are in leaf. Hazel growths are best for Runner Beans, and if long, straight rods of not too great a thickness are selected, they should last for several years.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

General Work.—At the time of writing, the ground is frost-bound, a condition most suitable for wheeling or carting manure. Other operations which may be carried out are pruning, lopping, cutting hedges other than evergreens, and trimming Ivy on walls, although the Ivy is better left until March or April, so that a shorter time elapses before it is again covered with leaves. Evergreen hedges are better left until danger of hard frost is over.

Sweet Peas.—If not already done, the ground should be prepared for Sweet Peas. Remove the top spit and lay it aside, then turn over the second spit as deeply as possible—even if it is of clay it should be broken up well—and add a good quantity of manure and, if obtainable, fresh turf edgings and similar material, which are, I consider, preferable to a too heavy dressing of manure; the resulting flower spikes may not be so long, but the blooms will be better placed. Make the bottom layer of soil firm and leave the top spit exposed to the weather for a month or two. When filling the trench add material similar to that prescribed above, also some ground bones.

Onions.—Where these are grown for transplanting, the middle of January is an ideal time for sowing the seeds. Boxes, three inches deep, are most suitable; some old flaky manure or leaves should be placed in the bottom for drainage. The compost should be fairly rich and not wet when used. It should be passed through a half-inch-mesh sieve and the box then filled to within half-an-inch of the top; the compost should be made firm around the edges of the boxes, but do not ram the whole too firmly. Sow the seeds rather thinly and cover them with soil, after which press the surface firm, water and cover with a piece of glass and paper. Place the box in a warm house until germination has taken place, after which the seedlings should be removed to a cool house and kept well up to the glass. Do not allow the soil to become dry, but avoid overwatering.

Lettuce, Early Cabbage, etc.—Seeds of Lettuces, early Cabbages, Cauliflowers, Parsley and Leeks may be sown at any time; they may be treated as advised for Onions. The glass over the seed-boxes should be turned every morning and the progress of germination watched carefully, as a day too long in heat and darkness may result in the seedlings becoming drawn and weak.

Euphorbia jacquiniaeflora.—A good batch of this subject is most valuable at the present time. I find it is best to root fresh cuttings every year, but it may be grown on into much larger plants, being a true shrub. When the plants pass out of flower they should be placed in cooler quarters and kept dry at the roots to rest them for a few months. In April or May they may be re-introduced into heat and sprayed regularly until growth commences. As these growths reach three inches in length remove them with a heel and insert three or four together in a two-inch pot of very sandy soil, which should be placed in a close case. When rooted, the cuttings should be potted on and grown in heat until July, when they may be hardened off and grown in cold frames for seven or eight weeks, after which they should again be returned to warm greenhouse conditions. They prefer a fairly rich, sandy compost, of two parts loam, one part old manure, and one part leaf-mould. Five- or six-inch pots are quite large enough for the final stage, and no pinching is necessary.

INDOOR PLANTS.

SCHIZANTHUSES AND NEMESIAS FOR HANGING BASKETS.

Two plants which deserve to be more widely used as subjects for hanging baskets are the Schizanthuses and Nemesias. I have found the large-flowering hybrid Schizanthuses and the small-flowering Nemesias to be the most suitable. Seeds of both should be sown during the early part of September in light soil and placed in a temperature of about 60°. Prick off the seedlings into small pots when ready, using an open compost, and grow them on in a cool house, care being exercised at all times to avoid over-watering, as these plants are peculiarly susceptible to damping-off.

When the Schizanthuses are ready for five-inch pots, choose the largest specimens and plant one in a ten-inch or twelve-inch basket, using a compost of one part loam, and half-a-part leaf-mould and sand, adding a little bone-meal and wood-ash. Hang the basket in a cool house near the roof-glass, and do not give water until the plant is established. Tie down the growths as they become long enough, arranging them equally around and under the basket, but preserving a few of the central shoots to furnish the chains by which the basket is suspended. Before flowering commences the basket should be entirely hidden. Liquid manure and soot-water applied alternately at this period will be beneficial. I have seldom found it necessary to practice stopping the plants. If kept growing steadily during the winter, a gorgeous display of blossom will result, as the accompanying illustration (Fig. 21, p. 43) shows.

Nemesias should be stopped occasionally to promote a bushy habit, one plant being placed in a six-inch basket, or three plants in a twelve-inch basket. The same cultural directions should be followed as for the Schizanthuses. The use of excessive heat and moisture will result in failure. *E. J. Bryant, Queenswood Gardens, Englefield Green.*

CRASSULA LACTEA.

As a winter-flowering plant for the greenhouse or window, this comparatively little-grown Crassula is ideal. About mid-December it produces its spikes of tiny, pure white flowers. These are four to six inches in height, and very graceful in appearance, being equal in all respects to those of Roman Hyacinths. The growth of the plants, when raised annually from cuttings, does not exceed three inches.

Propagation and cultivation are simple. In February or March, insert five cuttings in a five-inch pot filled with an open, sandy compost and well-drained. Place them in a greenhouse, where they will soon root, and then grow them on in a sunny frame or in the open during the summer—they do not require any further potting on—and if, in early autumn, they are placed in a light position in a house just kept free from frost, they should flower freely in due course.

The whole secret of success lies in growing the fruits under cool conditions throughout all stages of growth. After flowering, they will send up many basal growths which serve for cuttings to provide a successional batch.

SENECIO CANALIPES.

Undoubtedly one of the best winter-flowering climbing plants for the cool greenhouse, this member of the Groundsel family does not appear to be at all well known. It is not included in the *Kew Hand List* (although cultivated in the Succulent House at Kew), Nicholson's *Dictionary of Gardening*, or Bailey's *Cyclopaedia of Horticulture*, nor, so far as I can ascertain, is it mentioned in any trade list published in this country; this is to be regretted, for it is an excellent plant in every respect.

It belongs to the same section of the genus as the better-known S. macroglossus, and is a vigorous grower, bearing lobed, heart-shaped leaves which are of a somewhat succulent nature. From November onwards, for a considerable period, the showy inflorescences are in evidence. The flowers are borne in terminal, branched corymbs; they are loosely arranged, and each is about three-quarters-of-an-inch in diameter. The ray florets are few in number and a bright yellow, while the rather small disc is of a deeper and duller colour.

At Kew, it thrives planted out in a small border formed on the stage, and trained to the rafters in such a position that it can obtain the full benefit of all the available sunshine. It is propagated readily by means of cuttings inserted in a sandy compost. *T. H. E.*

ALPINE GARDEN.

CONVOLVULUS NITIDUS.

The late Reginald Farrer, after extolling the beauties of this species, concluded with the statement: "It seems an awfully shy flowerer." That is just my own experience. For a good many years the plant has been prospering abundantly in so far as growth is concerned. It has spread over a considerable space at the margin of a dry, stony border, and colonised a square foot or so of the adjoining path. Now and then it flowers, and the big, rosy-white cups are so beautiful and have such a perfect setting in the hoary greyish-green of the short, leafy tufts, that one only wants many more of them. But what C. nitidus lacks, and why it persists in rambling about at the expense of its flowering propensities I, at any rate, have not been able to divine. There is some consolation to be derived from the fact that I am not alone in failing to flower this charming subject more successfully. Nevertheless, that does not make me any the less anxious to learn whether some such magician as Mr. F. W. Millard has managed to satisfy it, and, if so, how. We read of it growing naturally in rock fissures and gravelly barrens, so that root-restriction and a hard life may be the key to its loveliness. *J.*

ALYSSUM WULFENIANUM.

Quite distinct from the better-known and popular Alyssum saxatile, a familiar plant in the great majority of gardens, is A. Wulfenianum, from the Alps of eastern Europe, and withal a really attractive alpine plant, never so charming as when trailing over a large rock, its twisting and brittle growths clothed with rounded and fat, silvery-grey leaves, and terminating in rather large heads of somewhat loosely packed, clear pale yellow flowers, with notched petals. These are produced during late spring or early in the summer.

A. Wulfenianum is not common in gardens of this country; I know of no British nursery which offers this species for sale, although it may be obtained from several continental firms which deal specially with alpine plants.

It does not seem to be long lived, in fact, after a few years—a trait also of the better-known Alyssums—it begins to present a rather ragged and untidy appearance, when it may be replaced by young plants, which may be raised quite easily from cuttings rooted in a bed of sand in a cold frame during the summer.

Like all the members of the race, it delights in full exposure to the sun, while the soil in which it is planted should be of a light nature, amply drained and containing an abundance of chips and small pieces of rocks. A. Wulfenianum is closely related to the even more beautiful and rare Alyssum idaeum.

ANTENNARIA DIOICA.

Of the many low-growing, carpeting plants generally planted on the rock garden, one of the most useful is Antennaria dioica, which forms a rapidly spreading mat of bright, silvery-leaved rosettes. There are several colour forms of this species, the most attractive being A. d. hyperborea, with deep rose-pink flowers.

A. dioica has a wide natural distribution, and is described as being common in northern Europe, Asia and America to the Arctic regions, and in the mountain regions of central and southern Europe, and Russian Asia. It is quite common in Scotland, Ireland and Wales, and is frequent in many parts of England. In its several forms it is attractive, for the Composite flowers—small "Everlastings" on stems two or three inches high—are produced freely, but it is as a bedding plant to Crocuses and other delicate subjects that this silvery-leaved Antennaria is most useful.

One of the most charming effects I have ever seen created by its use was in conjunction with Iris reticulata, planted thickly among it, and the delicate Iris blooms looked very charming above the silvered groundwork, which, incidentally, continues attractive throughout the year.

A. dioica is the easiest of subjects to establish. It is not particular with regard to soil, and delights in a warm, sunny situation, while the creeping stems root along their lengths as they extend, and so make it easy of increase. *M. W.*

HARDY FLOWER BORDER.

HELIANTHUS ORGYALIS.

One of the latest species of Helianthus to bloom is H. orgyalis; in fact, in cold districts, and when early frosts are experienced, its floral beauty is often prematurely marred, yet this fact alone should not deter the planting of it at the back of the herbaceous border, or in groups in the wild garden, for which latter purpose it is excellently adapted.

As grown in this country, this herbaceous perennial is, perhaps, more attractive in foliage than in flower, for its stately, erect stems, rising to at least six feet, and often considerably more, are closely packed with long, slender, linear leaves, which droop gracefully over each other and so make picturesque columns of verdant green leafage. In autumn, the stems lengthen rapidly, thereby spoiling the charm of the foliage, into long panicles of small, bright yellow flowers, which, provided they are not destroyed by frosts, provide a bright splash of colour for so late in the season.

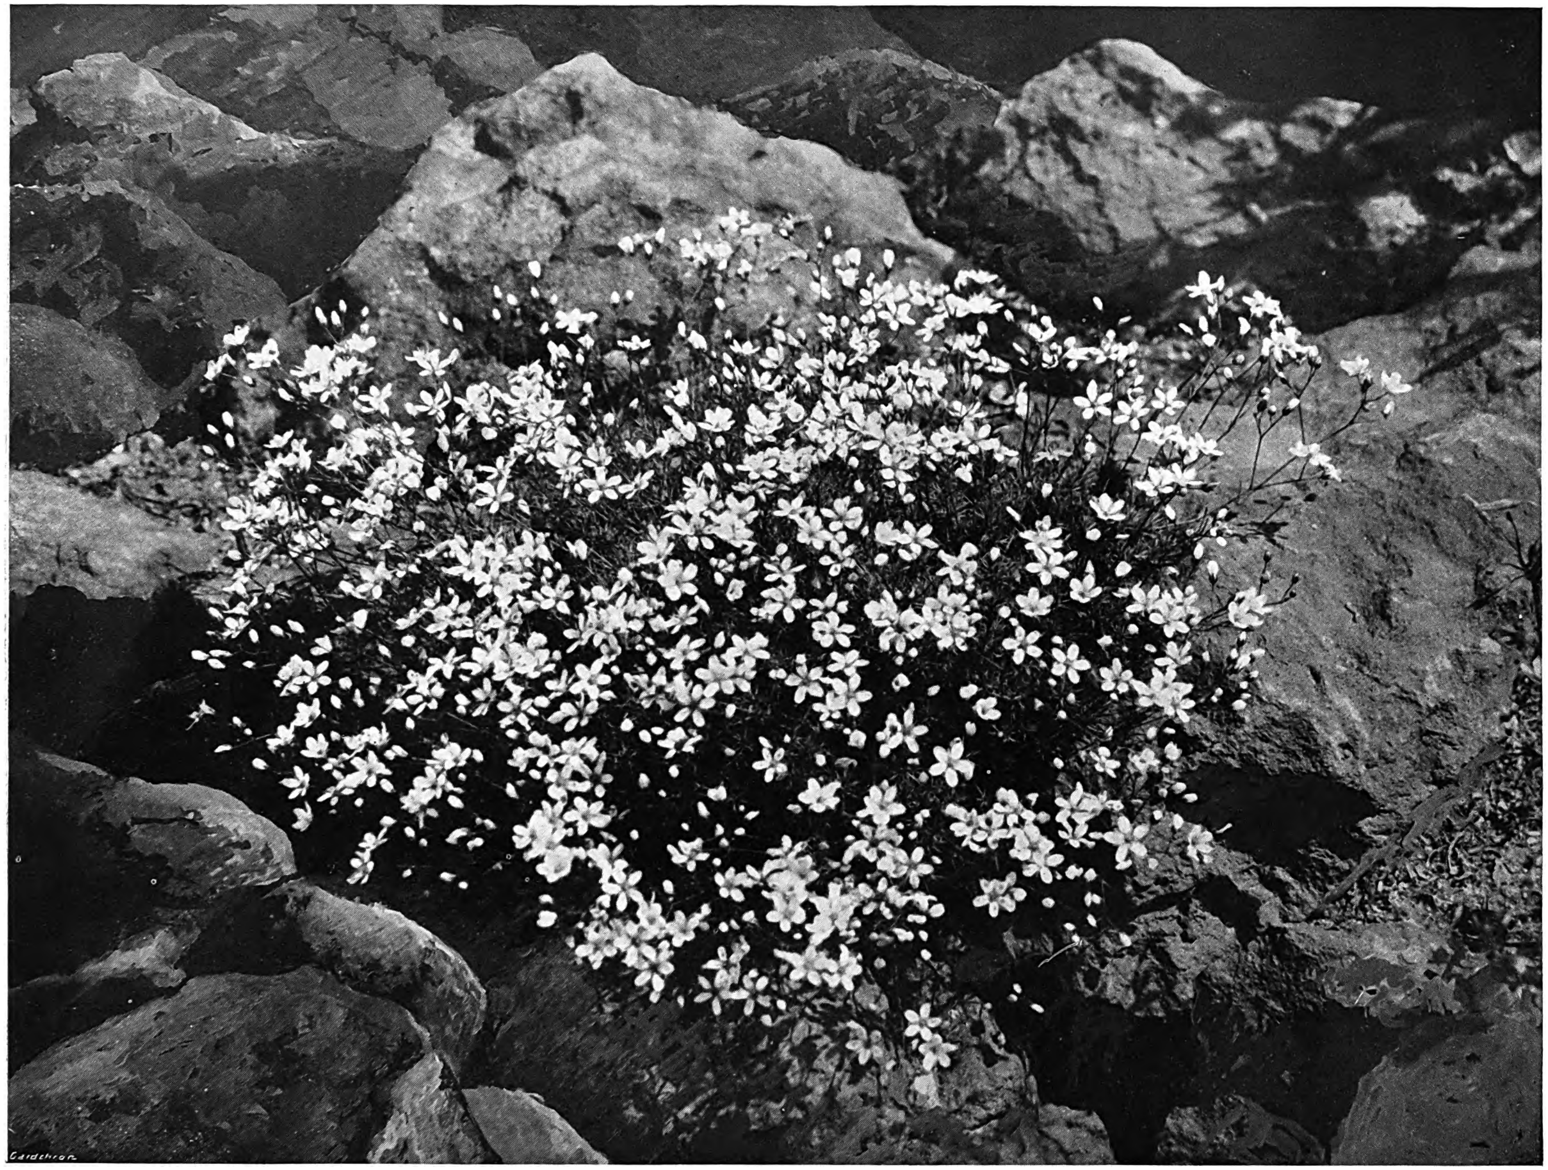
H. orgyalis, although hailing from a warmer climate—the dry plains of Nebraska and Texas—survives the severest winter with impunity and responds, under cultivation, to liberal treatment, although it is not, like many of its relatives, addicted to spreading too rampantly, while it relishes a sunny, warm position, and deeply worked, well enriched soil. It is, of course easily increased by division. *W.*

HELICHRYSUM BRACTEATUM.

When Mr. Ingwersen sent me this plant some time ago, a recent experience with a few other Tasmanians did not tend to raise my hopes as to the prospects offered by this newcomer. But H. bracteatum has, in every respect, lived up to the recommendation that came with it. Last winter it endured as much as 23° of frost on more than one occasion, and even the severe weather which succeeded a very mild February did not affect it seriously. H. bracteatum may, therefore, I think, be considered robust enough for most places, and it is a plant that is also sufficiently distinct to win for itself recognition in good company.

A sound perennial with a dark green, slightly bristly foliage, H. bracteatum puts up nine-inch flower-stems which break into bloom during the later summer and autumn. Unlike most of the perennial Helichrysums in cultivation, the flowers of this species are a burnished golden-bronze, egg-shaped, and about one-and-a-half inch in length. These not only invariably arrest the attention of those interested in the unusual, but they happen to blend very sympathetically with the prevailing tints of autumn. H. bracteatum appears to be a sun-lover, and although it is not fastidious as regards soil, so long as this is freely drained, I rather think it needs a fairly good loam. *A. T. J.*

Supplement to THE GARDENERS' CHRONICLE.



ARENARIA LEDEBOURIANA.

NOTES FROM GLASNEVIN.

It is generally agreed that Conifers do not flourish in or near large cities or towns, and probably for this reason, coupled with unsuitable soil, some of the Conifers at Glasnevin are by no means equal to specimens flourishing in Wicklow and other rural districts in Ireland.

That the site of this garden was once more suitable than it is now is evident by the proportions attained by certain old specimens still extant, but of rugged and worn-out appearance. In the middle of the Pine Hill still stands a fine bole of Abies nobilis, tall and straight, surmounted by but a few straggling branches, yet this tree is a proof of the purer atmosphere of probably seventy years ago, when Dublin city lay miles away. Certain Cedars, too, obviously of great age, both Deodars and the Lebanon Cedar, testify to the better atmospheric conditions of earlier times. Within the past few years Dublin, in common with other urban areas, has experienced a boom in building and houses rise like Mushrooms in a night, showing up in directions where less than ten years ago nothing but green fields stretched so far as one could see. That a sooty deposit is rapidly accumulating on the leaves is soon apparent when working through the collections, from the blackness of one's hands. How long, therefore, Conifers will continue to succeed here is a problem, but there is little doubt that some are already suffering.

Of those that appear to find the conditions most unsuitable, the Abies undoubtedly come first; there is barely one presentable specimen of the genus in the whole collection. This I attribute to three causes, unsuitable soil, smoke, and spring frosts. In previous notes, I have alluded to the damage done to the newer species by frost, and although they recovered remarkably during last spring and summer, there is a yellowing and dropping of the older leaves not compatible with perfect health. Liability to attack by aphis seems to follow any check to growth and accounts for some, but not all, of the leaf-dropping.

Piceas are in somewhat better state, but the number of really good specimens is limited. Without reference to sections, one may mention P. orientalis not yet showing any injury; the Common Spruce, P. excelsa, fairly good; and the Serbian Spruce, P. Omorika, unaffected and forming one of our best and most beautiful specimens. Many comparatively young plants of the newer Chinese Piceas are included in the collection, and these, so far, continue to grow fairly well, yet they are distinctly more sparse in leaf than the same species farther from Dublin.

The Douglas Fir, Pseudotsuga Douglasii, may be dismissed as a lime hater, and, but for collection purposes, not worth planting here, although a noble tree where lime is absent and other conditions suitable. The Tsugas are a mixed quantity, for although no notable specimens can be claimed, yet T. Pattoniana and T. diversifolia retain their normal green colour, while T. Sieboldii and T. caroliniana become yellow in leaf at once.

Turning to those Conifers that do best under the conditions of soil and atmosphere here, there is little to choose between Pines and Cypresses (Cupressus). Most of the Pines hardy enough for our climate do very well, and there are quite good specimens of the older and better-known species. The newer species from China promise well, and there are flourishing young plants of P. sinensis and its varieties growing, it must be admitted, in good soil, which years ago replaced what was little more than gravel. The Mexican Pines are barely hardy enough for Glasnevin, but a healthy plant of P. Montezumae is probably twenty feet high, and the mountain form of this species, P. Hartwegii, promises well. P. patula, although the "needles" are browned at the tips in winter, makes good annual growth, and so does P. Ayacahuite, nearly related to the Himalayan P. excelsa, which also flourishes. A young plant of Pinus Greggii is healthy and beginning to grow well.

All the forms of Cupressus Lawsoniana flourish, and for many purposes there is no better Conifer, some of the glaucous and golden varieties being unexcelled for ornamental planting. The Japanese species, C. obtusa and C. pisifera, make good specimens in good soil, but languish and become stunted in dry, gravelly soil. Cupressus glabra is growing rapidly, and apparently finds the conditions tolerable in the meantime. This, if it continues to flourish, promises to be an interesting tree. Of columnar habit when young, it is conspicuous among other green species by reason of the silvery-grey leaves. A similar plant is named C. arizonica, which is said to differ from the former in the absence of resin glands on the leaves, and there is a pendulous form (Fig. 22). Cupressus lusitanica, the Cedar of Goa, grows fairly well, but becomes thin and bare at the base eventually, due, perhaps, more to frost and cold winds than unsuitable atmospheric conditions; it usually shows a distinct browning of the ends of the shoots in winter. C. cashmiriana, although tried in a variety of positions, refuses to live in the open, and only one small plant of C. formosensis has survived, and is not progressing. I cannot state whether the failure of C. formosensis is due to atmosphere, or whether it is a lime-hater, but I am told that it grows well in districts subject to greater cold. Other of the commoner species, such as C. macrocarpa, C. nootkatensis, C. sempervirens, etc., are still flourishing. Junipers on the whole continue to grow satisfactorily, the few exceptions being due, probably, to unsuitable soil.

Thuyas vary—the older specimens of T. occidentalis and T. orientalis are no longer flourishing—and the best of the genus are T. plicata and T. (Thujopsis) dolabrata, the latter a handsome and attractive Conifer.

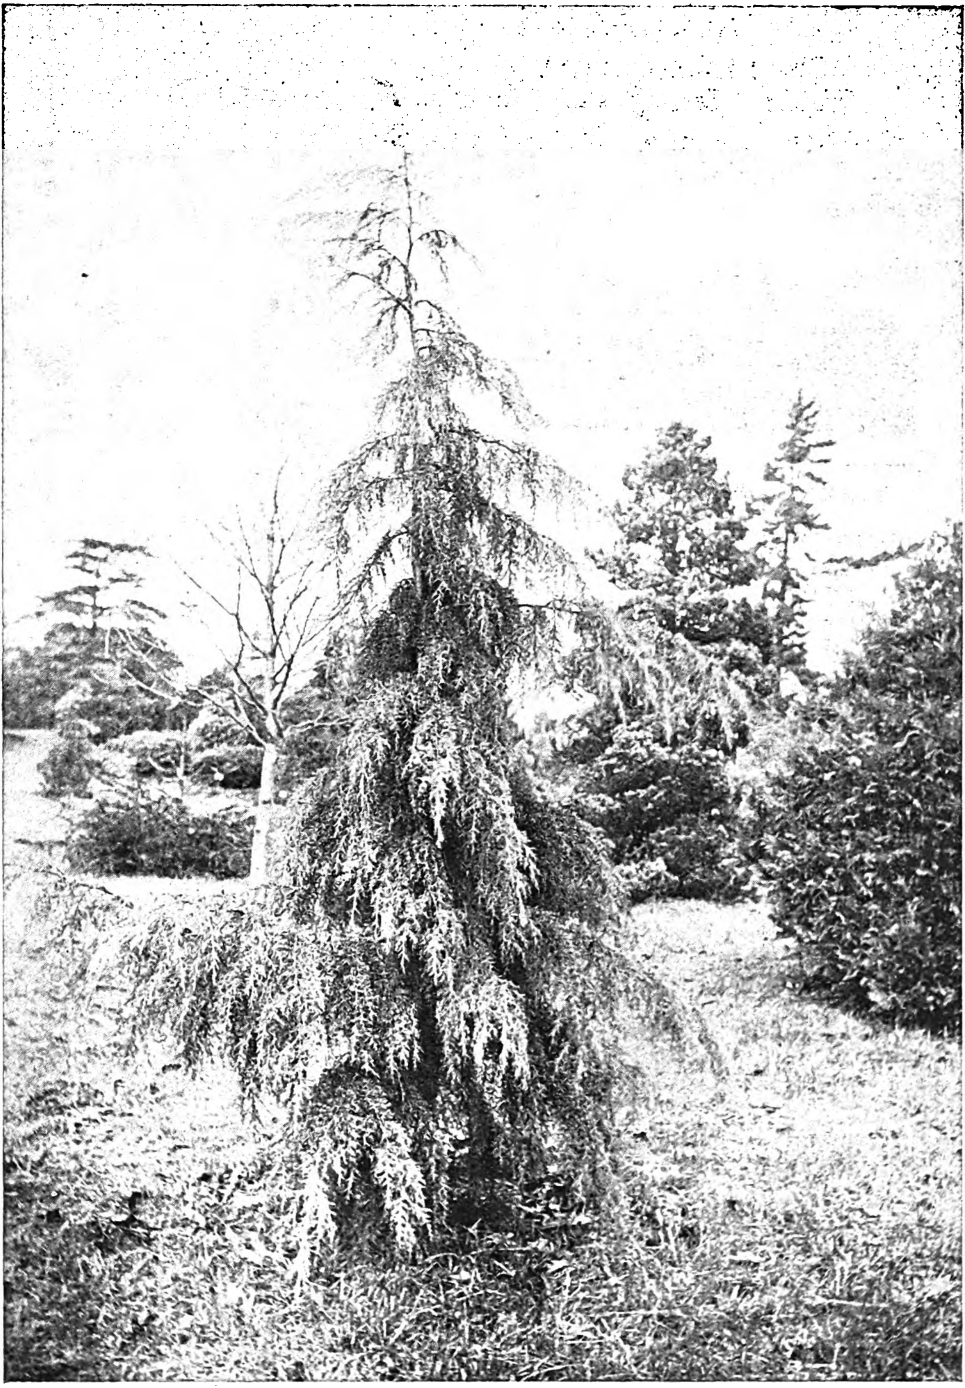


FIG. 22.—CUPRESSUS ARIZONICA (GLABRA) VAR. PENDULA AT GLASNEVIN.

The Common Yew grows remarkably well, and is represented in many varieties. Prumnopitys elegans does very well and is as hardy and vigorous as the Yew, but Saxegothaea conspicua is not a success, due chiefly to unsuitable soil and perhaps to being tender.

Numerous other Conifers might be alluded to, but enough has been said to show that arboriculture near a growing city has many problems. If a Conifer, which is generally known to be hardy, refuses to grow in the open at Glasnevin, we are inclined always to blame the limy soil or the deteriorating atmosphere. *J. W. Besant, Glasnevin.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XI.—Off.

March 1 saw five of us bowling along the Rima Road in the Political Officer's car. For the first fifteen miles or so, it is quite a good road, along the top of an embankment well above flood level; further on, the new work had not had time to settle, and it was not long before we found ourselves over the axles in soft clay, at a complete standstill, for the heavy car was carrying a big load (Fig. 23). However, we dug it out and got going again. Presently we crossed the Digaru river (Fig. 24), which at this season runs in a few shallow streams in a bed a quarter-of-a-mile wide. In the rainy season it is impassable for a car, and, of course, all temporary Bamboo trestle bridges are carried away.

The jungle through which we had been driving is very fine, and the road at this time of year was illuminated by the scarlet Erythrina indica. Enormous specimens of Terminalia myriocarpa and Bombax malabaricum were seen, besides Fig trees in great variety; very common also were the huge-leafed Pterospermum acerifolium and the dreary looking Duabanga sonneratioides. This last was also in flower and much visited by small birds, especially minivets, apparently seeking flies; the flowers being very brittle, there is a constant rain of floral fragments under the trees. We got as far as Teju, on the Lohit, that day. The cart road goes on another eleven miles to Dening, but with a big car so heavily-laden, it was considered advisable to go no farther; and the Political Officer, after an hour's fishing in the Lohit (Fig. 26), went back to Sadiya, leaving us to our own devices.

Next day, we walked the remaining distance to Dening, which is the last outpost on the road, altitude 2,290 feet. On the following day, we sent off some of our loads to Theronliang, over the ridge, and we ourselves followed on March 5.

Dening has an enormous rainfall, catching the crest of the cloud spate as it sweeps across the plain to the hills. In 1925 the rainfall was 269 inches; in 1926, it was only 217 inches. Then in 1927 it rose to 313 inches, 24 inches falling on July 7! Practically all the bridges were washed away during that deluge, and the hill road melted away like a snowball at midsummer. April and July-August are the wettest periods.

During two days spent there, I collected Jasminum anastomosans (with unpleasantly sweetly-scented flowers), Viola, Impatiens, and a form of Thunbergia laurifolia, with cream flowers, faintly tinged with violet; several ground Orchids, a Leguminous tree with fluffy, fragrant, cream flowers, like Calliandra; a Clematis in fruit (probably C. smilacifolia), and Chirita. In the jungle, I picked up the fruits of a Spondias—oval, and as black as Morello Cherries—Kydia calycina, which is a very common tree, and a Michelia. The jungle is, of course, evergreen, but few trees were in flower.

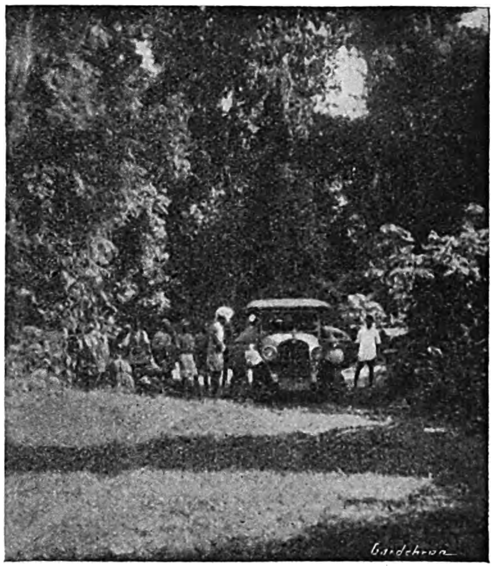

FIG. 23.—THE LOHIT VALLEY ROAD: BOGGED.

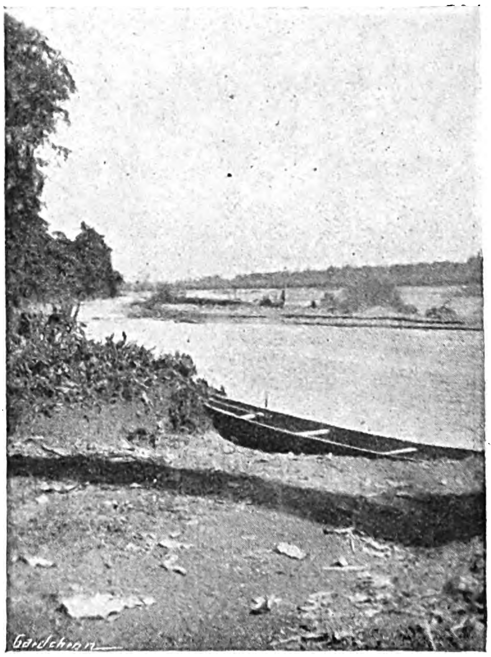

FIG. 24.—DIGARU RIVER, ON THE WAY TO DENING; LOHIT VALLEY ROAD.

At Dening we were still in touch with Sadiya and with civilisation. Dening gets a mail once or twice a week. It has one shop, and also a canteen for the outpost, where we could buy a few tinned provisions. We could telephone to the Political Officer, and get a reply within an hour. But after we left this haven, there was nothing more to hope for, should things go amiss. Appropriately enough, we started in the rain on March 5, and as we climbed it turned to a downpour. We reached Dreyi, 5,140 feet, in the afternoon, and then came a terrific thunder storm, with a deluge of rain; some of the loads, including my bedding, did not turn up that night, but we kept a big fire going in the bungalow, while the thunder banged from hill to hill and the lightning glowed through the rain, mist-like—an arc lamp in a London fog.

The weather improved for the final climb to the saddle, 6,000 feet, and as we descended into the sticky Tidding valley, the sun shone out again. Theronliang, 1,930 feet, by the Tidding river, is the last bungalow on the Lohit valley road, mile 72. So rarely is it visited by officers from Sadiya that there were only half-a-dozen names in the visitor's book since I had signed my name in December, 1926!

So we settled down for our last few days in a house, and fished and botanised while the Mishmi interpreter scoured the thinly populated valley for coolies. There are some remarkably big Sago Palms a short way up the hillside, and near the summit of the ridge, at 5,000 feet altitude, a big deciduous Magnolia grew. At the top of the saddle, I found a large-leafed Castanopsis with uncommonly large fruits, and in the jungle, common trees included Sterculia colorata, Caryopteris, Terminalia myriocarpa, Saurauja napaulensis, Ficus Cunia, Cinnamomum and a Pandanus; climbers included Combretum and a big climbing Jasmine closely allied to J. scandens, which was just coming into fragrant flower. The fruits of Sterculia colorata look like leaves, being thin and opening quite flat, with one seed attached to each suture near the base; the natives eat these seeds, and, in fact, they have a pleasant, nutty flavour. Apart from the trees, few of which were in flower, there was not much of interest here, the valley being choked with dense jungle except for scattered patches of cultivation and secondary growth indicating former cultivation. The jungle is always poor in flowers, and the season was not yet far enough advanced. Our best hope for herbaceous stuff lay in the high bank of the path which slanted to and fro up the steep ridge for 4,000 feet to the saddle. Here the violet Chirita grew luxuriantly on rocks where the shade promised sufficient moisture on sunny days, while Violets revelled in the sunshine—only they were never violet, but white or mauve, with striped lips. Here also was Impatiens, with flowers like the yolk of an egg for yellowness; purple Corydalis, Polygonum capitatum, and a white Begonia with large, nestling flowers. Another species of Begonia was also flowering—it grows erect, making clumps in dense thickets, often growing under bushes, and always in heavy shade. The flowers are white, in crowded, sessile clusters all up the stem, and the dark green leaves are thick and fleshy. Still another species, with small, narrow, pointed leaves, forms a regular bush, five feet high or more; it was not in bloom, but the flowers are white and squinny. A fourth species, which grew among the undergrowth, on heavily shaded banks, was conspicuous for its immense leaves, each leaf standing from two to three feet high on its thick, succulent stalk, and sometimes having the blade, which is smooth and glossy, so much as thirty-three inches from tip to base; I have not seen this ornament to the genus in flower. The natives eat the leaf-stalk, like Rhubarb.

One morning a troop of baboons came down to the river from the jungle on the opposite side to play on the sands; in the van came brown father, cautious at first, crawling sedately, drinking from the river, and then sitting up on a boulder, like patience on a monument, while he looked all around him; next brown mother, not quite so cautious, but more sedate; lastly, little hopping, light-coloured and light-hearted babies, frisking along and teasing each other. The jungle here came right down to the edge of the sand, and watching the same spot, we saw monkey after monkey emerge from the gloomy overhanging vegetation, and stalk out on to the warm, sunny sand. Then they all trooped off in single file to a favourite tree, which they climbed, and then sat down, some to eat nuts, others to swing themselves. Meanwhile, coolies were coming in, sometimes in twos and threes, sometimes in tens and twenties; and as they came, we packed off loads of rations, stores and instruments to the Delei valley, three days' march away. (It may be recalled that on my trip from Rima to Assam in 1926, I had marched from the Delei valley to Theronliang, under the sharp spur of necessity, in two days; but I was not anxious to repeat that performance!)

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, 1928, Vol. LXXXIV.

The genus Rubus is represented in this region by many species, most of them very aggressive, and none of them beautiful, the best being the dwarf, alpine species with large flowers. But for garden purposes even the best do not compare favourably with the North American species, such as R. deliciosus. Down in the valleys, wherever the jungle is cleared and the ground abandoned after cultivation, one or other species of Rubus presently springs up. The first to flower—it was already in bloom—is R. rosaefolius, closely followed by R. paniculatus and R. lasiocarpus, the last-named having pink flowers. The fruits of all are edible, and thin as the flavour certainly is, one eats them greedily, thankful enough for any fruit in the jungle; a statement which may surprise some of our writers of tropical fiction, who fill their jungles with rare and refreshing fruits. "Rare" is, perhaps, right! However, by April, the yellow Raspberries of R. ellipticus were ripe in the hills, and we found them quite delicious. In the clearing all round Theronliang bungalow, Cynoglossum amabile was a weed, and had been flowering throughout the cold weather.

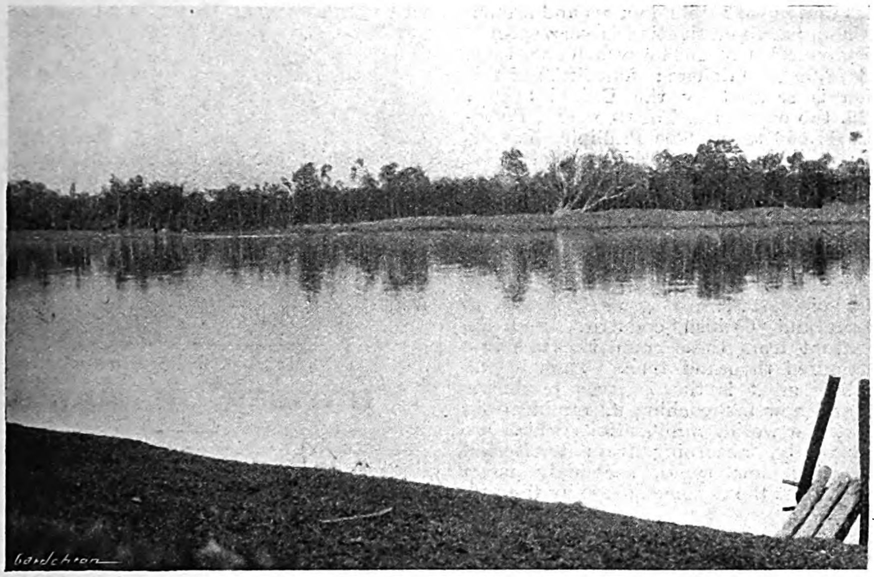

FIG. 25.—RIVER AND JUNGLE SCENE IN ASSAM.

On clear days we could look right up the Tidding valley, far beyond the banks of tropical forest on either side, to high, snow-clad peaks, which formed part of the Delei watershed; and, right opposite our door, the mountains rose in an almost vertical wall to 8,000 or 9,000 feet. Stewing as we were in the growing heat and dampness down below, even these glimpses of the promised land were enough to whet the appetite. So that when, on March 13, the last sixteen coolies required turned up ready for the road, we packed what remained to us, and started hopefully up the Lohit, on the second instalment of the journey. *F. Kingdon Ward.*

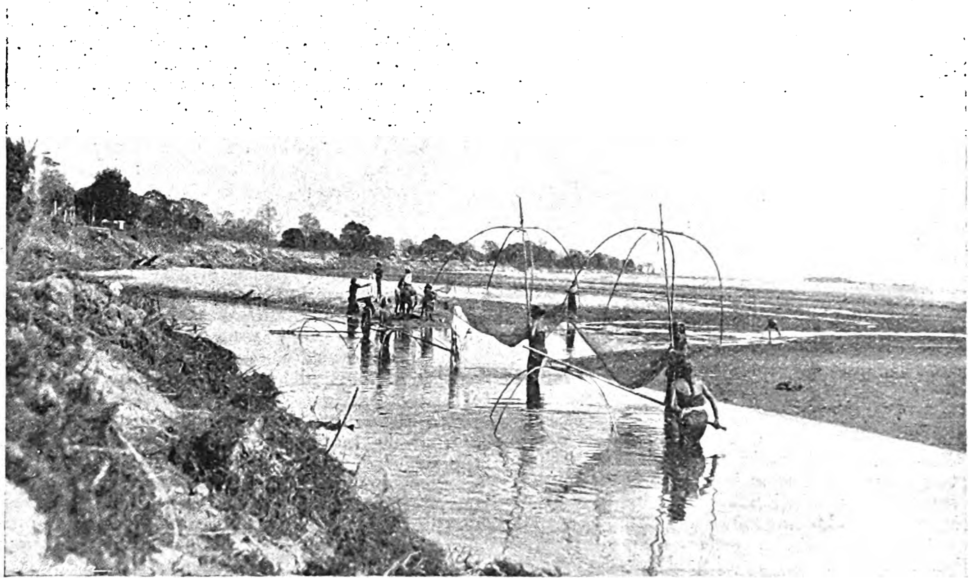

FIG. 26.—FISHING IN THE LOHIT AT SADIYA: DRY WEATHER.

THE FLOWER MARKET OF VENTIMIGLIA.

It is pleasant, if just a little disturbing to the peace of mind, to let one's thoughts at this season drift to the sunny south. And a bunch of Carnations in a show-window, especially if they are of that boiled red-Cabbage variety so popular along the Riviera, is quite enough to re-awaken visions of those sun-blest shores, and especially of Ventimiglia.

The flower market of that old frontier town, which latter is hard-by the far-famed gardens of La Mortola, is the Covent Garden of the south, the great wholesale emporium of a vast and wide-spread flower-growing population, at which enormous quantities of blossoms (it is not easy to estimate Roses or Violets by the ton) are disposed of every day throughout the winter to be distributed all over Europe. These flowers, the raising of which has almost entirely supplanted the historic Olive, are the most important product of almost every hillside and valley in this part of northern Italy. Indeed, almost the whole of the peasant population hereabouts seems to be engaged in this pursuit, and any day you may see them in procession, all making for Ventimiglia. Upon modern motor-lorries, antique wagonettes, superannuated buggies, two-wheeled mule-carts canopied by the hood of an abandoned motor-car, upon donkey-back, upon tram-car and by train, as well as upon the heads and shoulders of the people themselves, the flower-crop of this sunny land is borne to the principal trading centre of the coast.

The market hall of Ventimiglia is a large open shed, spotlessly clean, and its tall, white-washed columns lend to its obvious modernity a certain classical, almost oriental, dignity amid the green foliage of the Palms without. On the stone floor of the shed the huge daily output of flowers, contained in boxes and baskets of every conceivable description, is deposited, on arrival, in the numbered places allotted to each seller. But as the flowers are as yet all hidden from view by their wrappings of paper, cloth or matting, and as the dress of the peasants is not more picturesque than it is in any London market, the prevailing note is sombre, if not a little dull. But precisely at 3 o'clock, a dramatic change takes place. A policeman touches a lever, an electric "buzzer" resounds through the building, and the market is declared open. Then in a flash every cover is simultaneously whipped-off the flower baskets, and what was a moment ago a drab and uninspiring scene is now a kaleidoscope of vivid colours. Thousands of sheaves of blossom, each a good armful and tightly bunched for far travel, are being lifted out of their crates and stood on end. The air has become filled with fragrance, there is a rising hum and chatter of voices as buyers and sellers haggle over prices, shocks of lively colour are being unceremoniously bundled into baskets and into already over-loaded arms.

In a few minutes, certainly well under half-an-hour, it is all over. Scores of motor-vans laden with flowers are whirling east and west, the peasants are heaping themselves and their empties on to the heterogeneous collection of vehicles which lines every adjacent street, the people in the exchange offices are quietly sorting and counting their money, the sweepers cleaning the floor. The market has vanished as speedily as it came.

It was about the end of February, a year ago, that I was at Ventimiglia. At that time Carnations, small of blossom but with stalks nearly two feet long, formed the bulk of the trade. But there was also a big business being done in Roses, Stocks, Calendula, Mimosa, Anemones, Freesias, Violets, Irises and white Broom (Genista monosperma), with enormous quantities of the so-called "Asparagus Fern." Impressive and spectacular as this scene is, the flowers seen by the average visitor to Ventimiglia market are, after all, only a portion of the daily exportation from this part of the world. Every morning during the busy winter season the P.L.M. Railway Company runs a special train—"*Train des Fleurs*"—from Ventimiglia to the northern cities of Europe, and all its passengers are flowers. It is an argosy bearing in the gloom of its shuttered vans the fragrance and colour and sunshine of the south, while we in England are still waiting for the first outdoor Daffodils. *J.*

WORLD TOBACCO PRODUCTION.

Some idea of the magnitude of the Tobacco producing industry may be obtained from a perusal of a contribution dealing with this subject, which appeared in the November, 1928, issue of the *International Review of Agriculture*. Little did the intrepid Christopher Columbus realise—when, on November 6, 1492, two of his men, while exploring a "verdant island," observed some natives "carrying in their mouths some kind of firebrand, from which came small puffs of smoke," and which, upon closer examination, they recognised to be "a kind of strange dried herb rolled in a spathe of Maize"—the immense consequences that were to follow so small a discovery.

At the present time the cultivation of Tobacco is world-wide, extending from the Equatorial Belt—Sumatra, Cameroons, Brazil—to the cold lands—Russia, Baltic States, Germany. It was commenced in Europe early in the sixteenth century, the plant being brought from America by Spanish and Portuguese explorers, and since that time Europeans have been responsible for the spread of Tobacco growing into many distant parts of the world, while the Turks established it firmly in Asia Minor and the Balkans. As Tobacco production has increased, so has the consumption of it.

Nicotiana Tabacum, with its many varieties—fruticosa, virginiana, brasiliensis and havanensis—is the species grown commercially, but there are other species of historical importance, which are worthy of note. It is considered that N. rustica, which has, apparently, been grown from time immemorial on the shores of the Caribbean Sea, was the Tobacco discovered by Columbus, while the variety persica, of the ornamental N. petuniaeflora, yielded to the Persians the preparation known as *tombeki*—the Tobacco for "nargile" smoking.

Only the principal exporting countries are dealt with in the review referred to, and among these the United States of America is easily first, being far in advance of any other country. Cigar Tobaccos are grown chiefly in the north-east, their production being specialised according to soils, as the various types of soils have marked effects upon the quality of the Tobaccos grown. Some conception of the vastness of the output of such Tobaccos in this area may be gained from the fact that Connecticut has an annual production of 28,000,000 lbs. of two varieties—Havana Seed and Broadleaf; the State of New York produces about 1,000,000 lbs. of the Onondaga and Big Flats varieties; Pennsylvania has an output of about 45,000,000 lbs.; Ohio, 25,000,000 lbs. and Wisconsin, 30,000,000 lbs. Ordinary smoking Tobacco is grown chiefly in Kentucky and the neighbouring states — Kentucky 240,000,000 lbs., and West Virginia 6,000,000 lbs.; Virginia and the southern states—Virginia 130,000,000 lbs., North Carolina 468,000,000 lbs., and South Carolina 75,000,000 lbs.; and Maryland and Eastern Ohio, with a total production of 27,026,000 lbs.

The Indian Empire comes next in order to the United States in Tobacco production, the total amount produced in 1925, as estimated by the Tobacco Section of the Department of Agriculture at Washington, being 374,000 metric tons, but, generally speaking, the quality of Indian Tobacco is poor, owing chiefly to lack of care on the part of the planters. China produces Tobacco on a large scale, but it is difficult to estimate the amount grown, for, with characteristic Chinese economy, such huge quantities of cigarettes are exported that they absorb 21,000 tons of Chinese Tobacco and 19,000 tons of imported Tobacco; foreign capital is largely involved, and the Tobacco is produced by American methods.

In the Dutch East Indies, cigar Tobacco is the chief production—Sumatra supplies the "wrapper," Java the "filler." The Java crop is twice the weight of the Sumatran, but the Sumatran Tobacco is more than double the value of the Javan. The average production in Sumatra is 22,000 bales, while the output for Java, in 1925, was 563,000 bales. In Russia, the production of Makhorka cigarette Tobacco has advanced from 50,000,000 kilos in 1913 to 100,000,000 kilos in 1925, and it is considered that Russia should be placed third on the list of world producers.

Coming next to South America, Brazil exports Tobaccos essential for the preparation of fine cigars, the Brazilian production ranging from 500,000 to 600,000 tons per annum. Cuba, Porto-Rico and San Domingo hold an important position among Tobacco producing countries — San Domingo cigar Tobacco is unrivalled for its fineness and aroma, while in Cuba, where cultivation is very specialised, the production of 1923-4 was 10,000 tons, valued at 23,000,000 dollars; four-fifths of this production is secured by the United States. In 1925-26, the exports of Tobacco from Porto-Rico were 11,000 tons. The Phillipine Islands add their quota to the world production of fine Tobaccos, while Paraguay, although a small country, has a world reputation for the quality of its Tobacco, as also have Columbia and Argentina.

Oriental Tobaccos, *i.e.*, the yellow, aromatic and choice kinds used in the manufacture of luxury cigarettes, are grown chiefly in the Balkan and Turkish countries, and the annual output from these countries runs into several hundred thousand tons. Thus it will be seen how great is the Tobacco producing industry and how far-reaching its ramifications throughout the world, ramifications which are extending yearly, absorbing fresh territories, and producing new types, seemingly never sufficient to meet the demands made by the consumers. *F.*

USEFUL TRAILING PLANTS.

For the furnishing of more or less upright walls, for covering the stone edges of paths, or for clothing the larger, prominent stones of the rock garden, there is a host of plants of a trailing or creeping habit eminently suited to the purpose. The Acaenas are attractive plants for sunny positions, and quickly form dense, evergreen carpets, the glaucous foliage of A. Buchananii being particularly attractive. The Aubrietias are very popular and never look more beautiful than when allowed to trail over the crevices of a low stone wall, when they present a charming sight in the spring. There are many beautiful varieties varying in shades of colour, Dr. Mules being of a deep violet-purple; Fire King, rich crimson; Moerheimii, a soft rosy-lilac; and Lavender, a charming lavender-blue. Arenaria balearica is a tiny creeping-plant which covers large areas in a short time and bears myriads of small white flowers; it delights in a moist situation. Cerastium Biebersteinii and C. tomentosum are rapid growing plants with attractive grey foliage, but they are very rampant and should be given positions where they cannot easily encroach. Gaultheria procumbens forms creeping masses of glossy foliage, its small white flowers being followed by red berries, and it is particularly suitable for covering the edges of paths in shady positions. The smaller-growing Gypsophilas are ideal subjects for covering low stone walls and are sun-lovers. G. cerastioides is a true trailer, bearing a profusion of white and violet-streaked flowers; G. repens and G. r. rosea are also attractive plants of a creeping habit.

For dry, sunny positions, the Helianthemums are extremely satisfactory subjects, their pretty, dwarf, evergreen foliage being covered in summer with small, Rose-like flowers in various shades of pink, crimson and yellow. There are also many good double varieties which are very showy. Hypericum reptans, although not a true trailer, is a dwarf plant of spreading habit with pale green leaves and large, deep yellow flowers, and is valuable because of its late-flowering habit. Linaria Cymbalaria and its variety rosea are attractive trailing plants and thrive on walls, even in the driest positions. Lithospermum prostratum is one of the finest creeping plants in cultivation, its brilliant, blue flowers being borne most profusely for several months from the middle of May. It likes a well-drained soil and a sunny position, but succeeds also in partial shade. Few plants are more attractive than the alpine Phloxes when they are planted in a position where their shoots can depend over a low wall. Prolific with their flowers, they produce sheets of colour in April, May and June, and their large cushions of needle-like foliage are always attractive. There are many good varieties, among which may be noted G. F. Wilson, with lavender-blue flowers; Leila, pale rose-grey with a purple eye; Sprite, rose with a crimson eye; Vivid, bright carmine-pink, and setacea, soft pink. The Saponarias are trailers of rapid growth and are never better served than when provided with rocks to roam over. S. ocymoides splendens has large, rosy-crimson blooms and is a charming plant. Silene maritima fl. pl. is noted for its dense, spreading foliage which carpets the ground, the flowers being borne in rich profusion, appearing like small, double-white Pinks from June to September. The value of Veronica repens, one of the dwarfest of the Speedwells, should not be overlooked, as its pale blue flowers are very attractive; it is suitable for moist and shady positions. *W. A.*

NOTICES OF BOOKS.

Handbook of Fertilisers[*]

The first point that will strike the botanical student on opening this book for the first time is that sixteen chemical elements are essential for the growth of plants, including the previous ten thought to be essential. The new ones are manganese, boron, zinc, sodium, chlorine and silicon. Boron is only required in small quantity; much of it is injurious, and it occurs in large quantity in muriate of potash extracted from the brine of Searles Lake, but it is removed and utilised in the preparation of borax. Students of Pansies will quote zinc in the case of a certain Pansy. Sodium and chlorine were known previously in connection with Beet, Seakale and other seaside plants. Here it is stated that potassium can be partly replaced by sodium. In this country it has long been known that silicon serves to strengthen the straw of cereals. Another new note is that the fixation of free nitrogen can be carried on in the soil, under favourable conditions, by other than Legume bacteria.

The first chapter also deals with nitrogen, phosphorous and potassium, the three fertiliser elements it is often necessary to apply to soil in order to get good crops. Ploughed soil (weighing approximately 1,000,000 pounds to the acre) contains 400 lbs. to 2,600 lbs. of phosphorus, and 8,000 lbs. to 33,000 lbs. of potassium to the acre, but these are mostly locked up in minerals, insoluble in water and not available to plants. Free nitrogen and organic nitrogen are discussed, and why nitrogen is the most expensive part of mixed fertilisers—but that has long been known in this country.

Most of the sources of organic nitrogen (and they are not few) are dealt with. They are well-known in the industries of this country and often used in the natural state, including hoof and horn parings, wool waste, leather meal, feathers, shoddy, etc. All these, in America, are converted into more readily available states by being mixed with raw phosphate rock and sulphuric acid, and thus nothing is wasted. The best grade of dried blood is made into some kinds of buttons; the second grade is used for feeding animals; and the third grade only is left to the farmer for feeding his crops. Phosphates are obtained from much the same sources as in Europe, but the deposits in America are much more extensive. In Montana alone 34,000 acres are reserved on which settlers are forbidden. A good hint is that the phosphorous in basic slag does not change to less readily soluble forms in the soil as superphosphate does. The usual sources of potash are briefly mentioned; then the saline lakes of the States are passed under review. Searles lake in California is estimated to contain twenty million tons of actual potash, so there is no fear of a shortage for many years. The author states that 250,000 tons of potash are actually going to waste from various industries, and that alone would almost satisfy their fertiliser requirements (annual presumably).

---

[*] *Handbook of Fertilisers: Their Sources, Makeup, Effects and Use.* By A. F. Gustafson, Ph.D., Extension Professor of Soil Technology, Cornell University. Illustrated. New York: Orange Judd Publishing Company, Inc. London: Kegan Paul, Trench, Trübner and Co., Ltd., 1928. Price $1.25.

On page 29, a new fertiliser is mentioned under the trade name of Nitrophoska, which contains nitrogen, phosphorus and potassium, being a highly concentrated, complete manure. On page 74, the author warns farmers to exercise great care in the use of this and other highly concentrated fertilisers, and to make sure that these do not come into contact with the seeds, the germinating power of which they reduce. A chapter on the home mixing of fertilisers shows the farmer how to effect an economy by doing the mixing himself in early spring when little else can be done on the farm. Errors in spelling seem to be absent, but a repeated line of linotype muddles two sentences somewhat on page 4.

Bateson's Letters.

IN 1886, when Bateson, fresh from Cambridge University, was barely twenty-five and already absorbed in the evolutionary problems to which his life was to be devoted, he set off by himself to the wilds of Russia to study the *fauna* of the Aral Sea and other lakes of the Kirghiz Steppes, and in a sense, to observe the processes of evolution in the making. In particular, Bateson, in his youthful enthusiasm, had hoped that as the waters of the lakes of western central Russia varied materially in their composition, some being salt and others fresh, he would "have an opportunity of investigating the question whether these diverse environmental conditions produce any correlated changes in the structure of the animals (chiefly *Crustacea*) exposed to them."

On his return home, Bateson published the scientific results of his journey, and although, to his chagrin, he did not find the evidence he hoped he might find, his journey yielded much of extraordinary interest to biologists, and as much to travellers, who now have Bateson's account of his experiences* in the best of all forms—a series of intimate letters to his mother and sisters at home, all obviously written without a thought that they might some day be printed. But in collating these letters for posterity and editing them judiciously, Mrs. Bateson deserves well of her husband's many friends, for apart from the interest of the journey into a country but little known to Englishmen, Bateson's account of his experiences of the tragedies and comedies of life in the Steppes, in which he himself was as often the chief actor as one of the audience, makes most diverting reading. Nothing escapes the young man's observant eye, and his faculty for seeing the droll side of life carries him through more than one difficult situation, and adds immensely to the interest of the story.

Armed with letters of introduction to our ambassador at St. Petersburg, as it then was, and counting on his ability to push on to his destination with despatch, Bateson had his first experience of the leisurely procedure of official life, of which St. Petersburg had no monopoly, although it may have been carried to greater lengths there than in other capitals. Naturally, with all the impatience of youth, we see him chafing at the delays which tie him to St. Petersburg, making a ceremonial visit to this official or that, for which, at any hour of the day, he had to attire himself in dress clothes and a silk hat with a curly brim, of which there is a delightful thumb-nail sketch. He takes us with him through the interminable business of obtaining his papers and permits, without which, of course, he could hardly move a yard, and we battle with him at the Customs on the vexed question of the duty to be paid on his equipment. But for all Bateson's natural wish to shake the dust of St. Petersburg from his feet, his four or five weeks there were not mis-spent, for all the time he was making the acquaintance of *savants* and famous men in the academic and scientific world, and, incidentally, learning the first steps in the most difficult of all languages. Names familiar to botanists and gardeners continually crop up, for Bateson carried with him an introduction to Maximovitch from Lynch of the Cambridge Botanic Garden, who charged him to search for a particular Tulip. Maximovitch—"a dear little man; a very serious and gentle sort of person"—whose fluent use of our language put Bateson at his ease, had already done much of his botanical exploratory work in Japan and Russia, and not only encouraged Bateson, but made him an enjoyable companion. He found Regel, of *Gartenflora* fame, "an old boy of ninety but very active, and he turned up trumps." Later he met Kolpakovsky, whose name is familiar to Tulip growers and, as Governor of the Steppe Province, was to be of use to Bateson.

At last all was settled satisfactorily, and Bateson set off on a journey which was then a serious expedition, but would now be accomplished by train in a few days, for the branch line from Samara on the Trans-Siberian Railway to Tashkent, skirts the northern shore of the Aral Sea, and would have put Bateson down in the centre of his sphere of operations. The incidents of the journey to Moscow en route for Nijni Novgorod, where he took boat on the Volga to Samara and then followed the road to Orenburg—the gate of the Steppes—and thence to Irghiz, where Bateson made his first base, make a delightful story written with but slight restraint to those with whom he was entirely *en rapport*. Of all the delightful stories with which this enjoyable book is packed, that of the feast given in Bateson's honour by a Kirghiz sultan runs the rest close. Bateson's ceremonial attire on the particular occasion consisted of a pair of old knicker-bockers, black round tail-coat, and *cocked hat and sword*. The thumbnail sketches with which the stories are punctuated are alone a delight.

NOTES ON SOME RECENTLY DISCOVERED DWARF CONIFERS.

WITHIN the past few years several new dwarf forms of Conifers have been discovered and are worth recording.

The present unfortunate lack of uniformity in the nomenclature of Conifers makes it necessary to give alternative names for some species so as to avoid confusion here and in America.

PSEUDOTSUGA DOUGLASII (OR TAXIFOLIA) VAR. ASTLEYI.

This form has arisen from the propagation of a most interesting "Witches Broom," which was found on a normal tree near Chertsey, by Mr. Alfred Astley. As will be seen from the accompanying illustration (Fig. 27), the "broom" hangs down on two sides of the branch. The foliage is very pendulous, small and fine, and of a vivid, pale grass-green colour, and the terminal buds are madder-pink and not crimson in colour. The propagated plants have retained their unusual colouring and, judging from the density of their branchlets, will probably form semi-pendulous, cushion-like plants, similar in form to the smaller of the two "brooms."

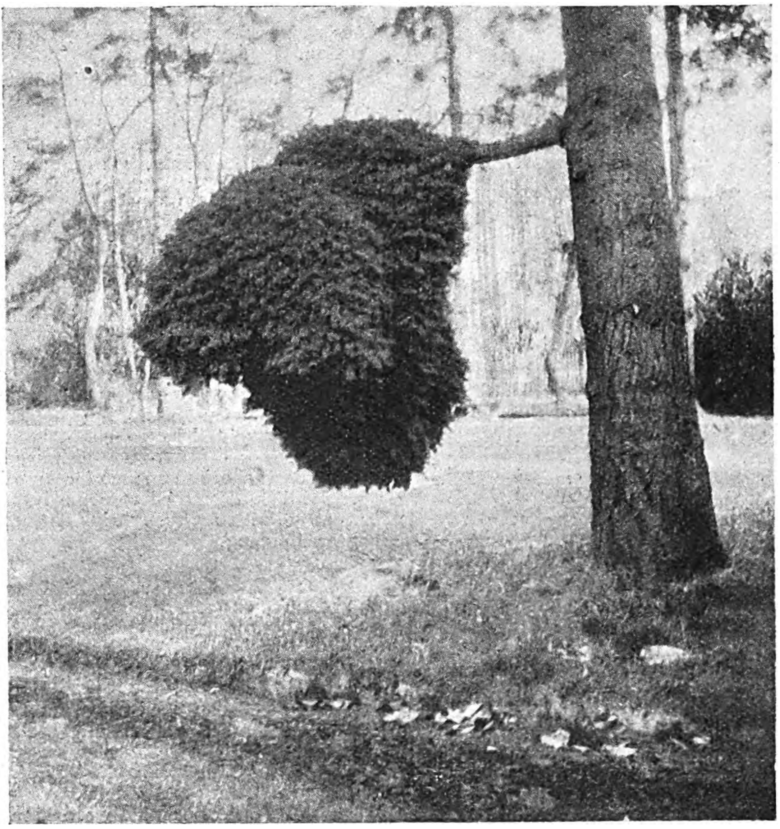

FIG. 27.—"WITCHES BROOM" ON PSEUDOTSUGA DOUGLASI, NEAR CHERTSEY.

PICEA EXCELSA (OR PICEA ABIES) VAR. ABBEYLEIXENSIS.

This I found in a plantation of normal common Spruce at Abbeyleix, Ireland, in 1911. It had made a low, slightly domed cushion about eight inches high by twenty inches across, and has increased very little in size in the intervening years. Its chief claims to distinction are its foliage and side branchlets. The former is rather long and fine and very pectinate in arrangement; the latter are all rather "curled over," giving each little branchlet the appearance of a small ostrich feather.

Cupressus Lawsoniana var. Ellwoodii.

At first sight, this might be mistaken for var. Fletcheri, but it is quite distinct. Its foliage is generally longer and thinner and still more glaucous; the inner foliage is not dark, like that of Fletcheri, but is also glaucous and very pale. The branches and branchlets of Fletcheri are all ascending and straight to their tips, with the foliage evenly spaced, whereas the branches and branchlets of var. Ellwoodii, although ascending, have their tips splayed and recurving, the foliage here being more densely crowded and decurving.

This was a self-sown seedling at Swanmore Park, Bishops Waltham, where it was found by the gardener, Mr. Ellwood, and transplanted by him to the rock garden. It has made a dense, compact, conical, little bush, about twenty-four inches high when I measured it in April last.

Thuya plicata aurea var. Rogersi.

This is a dwarf, compact, fastigiate, golden form raised by Messrs. Rogers of Southampton, and the mother plant, now fifteen years old, is thirty-three inches by nineteen inches.

Cupressus Lawsoniana minima var. aurea.

I also saw, in Messrs. Rogers's nursery, an interesting seedling form of Cupressus Lawsoniana var. minima named aurea. This is only a small plant at present and very slow-growing, but it bids fair to develop into a plant similar to var. minima in all respects except colour, that of the new plant being of a uniform gold all over.

Cupressus pisifera plumosa var. nana compressa.

This we must take to be the correct name for a plant exhibited under the title of "Retinospora plumosa nana compressa" at a meeting of the Royal Horticultural Society, in May, 1925. In either case an overwhelming name for a small, bun-like plant of inconsiderable dimensions, with very glaucous foliage intermediate between that of vars. squarrosa and plumosa—rather nearer to the former, but said by its raisers, Messrs. Van Nes, of Boskoop, to be a sport from var. plumosa.

Juniperus Wallichiana var. Loderi.

Two Junipers are worth mentioning: The first of these is a seedling form of J. Wallichiana, raised by the late Sir Edmund Loder, at Leonardslee. It has made a dense, small, fastigiate shrub, with very glaucous foliage. It has the appearance of a thick-set J. communis compressa, and when I measured it in 1927 it was about twenty-four inches high by about ten inches through.

Juniperus communis var. columnaris.

By this name we may recognise the very interesting fastigiate Juniper which one finds occasionally in nursery and private gardens, and which has the appearance of an overgrown J. communis compressa. Whether this is a reversion of the variety compressa, or a form evolved by repeated grafting of that variety on arborescent common Junipers, remains to be proved; but whatever may be its origin, the result is a most attractive, very narrowly-fastigiate Juniper, rather laxer in habit than var. compressa, and with foliage not quite so glaucous. I have seen several specimens between four feet and five feet in height, but not more. It is much slower and narrower than var. fastigiata (var. hibernica of the trade) and will be much in demand when it is better known.

Cupressus macrocarpa, Stewart's variety.

Messrs. Stewart, of Ferndown Nurseries, Dorsetshire, showed a tiny plant about fourteen inches by ten inches, at a meeting of the Royal Horticultural Society, in March, 1927. Its foliage was pale yellow, its adult branchlets tetragonal and the general appearance more like a form of C. obtusa, but it was stated by the raisers to have been grown from home-saved seed of C. macrocarpa, and to be eleven years old. *Murray Hornibrook, Ripley.*

THE YELLOW DAY LILIES IN AMERICA.*

For the gardener and plant lover, as distinguished from the commercial grower, many plants are invested with interest and value independent of their obvious qualities of merit and beauty. Such an interest gathers about all the Yellow Day Lilies. Even the commonly despised Tawny Day Lily, which so often has been cast out of gardens on to dump heaps, where it has established itself and spread, is a plant of romance, for the hand of man has carried it from its natural haunts in Asia and eastern Europe until now it is known over our own continent and acknowledged in many floras as an established exotic. For the scientist as well, it is a plant of singular interest, as it propagates itself freely by stolons and very rarely if ever by seeds. Special studies of its sterility have been made, notably by Dr. A. B. Stout, of the New York Botanical Garden, who by patient effort has accomplished what once seemed impossible, the securing of seeds from it by its own and other pollen.

Another old and widely distributed Day Lily is the Lemon Day Lily, which also has been carried about by colonists until it, too, is well known throughout our continent. This, unlike the Tawny Day Lily, has required no defender of its popularity nor heralder of its beauty, which is admitted by all.

Other species have come into gardens more slowly and are less well known than they should be. Two, the Amur Day Lily, Hemerocallis Middendorffi, and the early Day Lily, H. Dumortieri, which also masquerades as H. Sieboldii and H. rutilans, are now moderately well distributed, and the Japanese Day Lily, H. Thunbergii, is slowly coming into popular regard; but the gorgeous Orange Day Lily, H. aurantiaca, and the delicately-scented but somewhat less robust Citron Day Lily, H. citrina, are far from well-known. All these are Asiatic species of value for American gardens and will be described at some length hereafter, together with many hybrids derived from their inter-breeding.

Basis of Varietal Selection.

Just as any wild plant must show some singular beauty or carry some special virtue of fruit or flower to warrant its introduction into cultivation, so these selected plants must show some particular reason for meriting the attention which promotes them into the more select ranks of the flower garden.

The Day Lilies have various claims to such recognition, but even their most ardent champion can scarcely hope to obtain for them the affection lavished upon the Rose or the true Lily. Their very resemblance to the latter flower is, perhaps, their first claim to recognition, for their exquisitely modelled yellow flowers are almost the counterpart of some of the Lilies, although the plants and inflorescences are very dissimilar. In many cases they posses a fragrance as delicate as that of the Lilies and similarly exhaled with particular sweetness in the cool of the evening. Their colours show a range from the palest sulphur-yellows, through intense lemons, to orange and rusty reds. Some of the hues are of a singularly luminous character—a quality of great importance to one who is planning colour schemes in the perennial border.

For the gardener, whether professional or amateur, they combine three other qualities of prime importance: Permanence, tolerance of varied cultural conditions, and length of flowering season. The first two characters are, of course, interrelated, for under adverse conditions there could be no permanence. The only factors that appear to work hardship on these plants are extremes of summer drought and severe winter freezing of the semi-evergreen sorts. Both of these difficulties can be successfully overcome by the gardener if he chooses to supply water in dry seasons and uses a mulch of strawy litter for the tops during winter. Given these attentions, the Day Lilies are almost as permanent as Paeonies over our entire country.

By the selection of species and varieties, the season of flowering in the vicinity of Washington, D.C., can be extended over nearly all the summer months, and even from late April to September. In the district of Columbia the main seasons of flowering occur during mid-May, in the latter part of July, and in the early part of August, and relatively few sorts flower profusely through the latter part of June. The middle of August sees the gradual decrease of bloom in the summer-flowering sorts. Interbreeding is being carried on in various places and in time these gaps in the seasons should be filled by varieties intermediate in character between the sorts flowering in May and those flowering in July.

Tolerance of Varied Cultural Conditions.

As has already been suggested in noting their permanence and ease of culture, these plants are tolerant of various conditions of soil, exposure and climate. The natural preference is for a rich, moist garden soil, an open location with some shade during part of the day, and a climate that is neither excessively hot in summer nor cold in winter. Soils that are sandy and poor should be improved by the liberal addition of well-decayed manure or other organic material that will supply food and assist in the retention of moisture. Heavy soils which are poorly drained should be lightened to prevent standing water and severe freezing. Shade may be provided either by planting where the shadows cast by trees or buildings will fall over the bed during part of the day, or by the use of small flowering trees in the perennial borders.

The Day Lilies, unlike many flowering perennials, will bloom with some freedom under trees where, in addition to the shade, they must suffer root competition for both food and moisture. Situations more open are to be preferred, but some shade is almost essential for summer-flowering varieties of intense colouring, as the orange pigments are burned out by strong sunlight. These extremes of climate cannot be controlled by man, but by a careful selection of varieties some can be found for either extreme, the entirely deciduous species like flava, Dumortieri and Middendorffii being chosen for the north, and the evergreen or semi-evergreen sorts for the south.

For extensive plantings outside the cultivated flower gardens, some of the more robust species and varieties should be used. These should be planted in masses, as large as possible, to obtain the best effect.

Seed Production.

Seeds are produced rather sparingly by most species of Hemerocallis, even when hand pollenation is practised, for although many pods are formed, the seeds contained are often few in number. They are rarely offered in the trade catalogues. They should be gathered so soon as the capsules show signs of bursting, and may be sown at once or stored in a dry, cool, mouse-proof place until the following spring.

The early-flowering sorts ripen seeds in July, and as germination is rapid, often within ten days, the seeds may be sown at once to advantage. The small plants resulting by fall should be protected from heaving during the winter, but they are otherwise rather hardy. If they have not been transplanted the first summer they should be spaced in lines in the vegetable or cutting garden and grown to flowering size. There is considerable variability in the length of time for this, but many seedlings flower after two full seasons of growth. Nearly all the seedlings from chance pollenations are useful for garden decoration, but few show any great improvement over the parents, so seeds are not worth saving except from species, which alone reproduce truly from seeds.

The seeds of the summer-flowering sorts may be sown in pots or flats and wintered over in a cold frame or stored dry and planted the following spring. If they are sown at once considerable germination occurs within fourteen to twenty-one days, and the seedlings will require the protection of a frame to prevent winter-killing from heaving.

---

* By B. Y. Morrison, Senior Horticulturist, U.S. Bureau of Plant Industry. Reprinted, in substance, from Circular No. 42, U.S. Department of Agriculture, Washington, U.S.A.

Division of Clumps.

The Day Lilies are obtained from nurseries as plants and may be ordered for delivery either early in the spring as growth starts, or late in summer after their flowering. In the event of summer planting, care must be taken that there is enough water in the soil to produce immediate root action so that the plants may be established before winter. For the first winter a light mulch of straw will be helpful, even to those sorts that are entirely hardy when established.

After these plants have been growing in the borders, they need not be disturbed until the clumps begin to fail in flowering. They should then be lifted, divided, and reset after the soil has been well enriched. This fertilisation may be postponed considerably by deep preparation of the soil at the first planting and the annual addition of well-decayed manure dug into the soil in the spring.

There are two species (H. flava and H. fulva) that are stoloniferous in their growth and so may be divided easily by pulling apart the loose clumps. The other species and varieties form rather dense clumps, which should be lifted with a digging fork to avoid injuring the fleshy roots, and divided by cutting the somewhat woody crowns apart with a sharp knife. With the most robust species, this division may often be carried on until each fan of leaves is separated from the others, but not so far that there are insufficient feeding roots on each piece. A little experience in division will soon show the best practice. Particular care must be taken to establish divisions by good culture after replanting, or they may make new growths so slowly as to remain flowerless for a year or more. Division may be practised either in the spring or in midsummer. In summer transplanting the leaves should be cut to half their length, as is done when transplanting Irises.

After division and replanting in the summer, it sometimes happens that the deciduous species make no new leaf growth until the following spring and look as if they were dead or dying. The semi-evergreen sorts usually make a considerable growth of new leaves, which remain green through the winter, provided they are fully matured before frost.

In planting or replanting, the roots should be placed so that the base of the leaves is about two inches below the surface of the soil. The plants should be spaced about a foot apart each way for those that are cut to single divisions, and fifteen to eighteen inches apart for small clumps.

Choice of Varieties.

It is inadvisable to lay down any definite list of varieties for general use. This is particularly true of the named horticultural varieties. At the present time, these are relatively few in number as compared with the hosts of named Narcissi, Tulips, Dahlias, Roses or Irises, but they comprise plants that are likely to be of relatively permanent value, as well as forms that will surely be supplanted in time by plants of improved habit or style.

For the small garden, the species and varieties that should not to be overlooked might well include the following: Spring-flowering—flava, Middendorffii, Apricot, Gold Dust and Queen of May; summer-flowering—Florham, luteola, Sir Michael Foster, aurantiaca major and Thunbergii, together with any of the commercial strains of citrina hybrids.

A brief résumé of the species and varieties available follows, with an indication of other sorts possibly forthcoming. Unless specially noted, all have been grown in the writer's garden near Washington, D.C., and treated as any amateur might handle his plants.

In addition to a considerable number of seedlings as yet unnamed, the varieties here listed have been grown for these studies. The varieties that are not mentioned in the text have not been under observation a sufficient length of time to warrant their inclusion in this circular. Only those named in Italic type represent species and their forms; the others are garden hybrids.

Ajax, Apricot, *aurantiaca*, *aurantiaca major*, Aureole, Baronii, Chrysolora, *citrina*, Citronella, *Dumortieri*, Erika, Estmere, Flame, Flamid, *flava*, *flava major*, Florham, *fulva*, *fulva cypriana*, *fulva maculata*, George Yeld, Globe d'Or, Golconda, Gold Dust, Gold Imperial, Gold Standard, Kwanso, Lady Fermoy Hesketh, Lemon Queen, luteola, luteola grandiflora, luteola major, luteola pallens, luteola pallida, Mandarin, Meehanii, *Middendorffii minor*, Mrs. Perry, ochroleuca, Orangeman, Mary Queen, Queen of May, Royal, Sir Michael Foster, Sovereign, Tangerine, Thelma Perry, *Thunbergii*, Yellow Hammer.

(*To be continued.*)

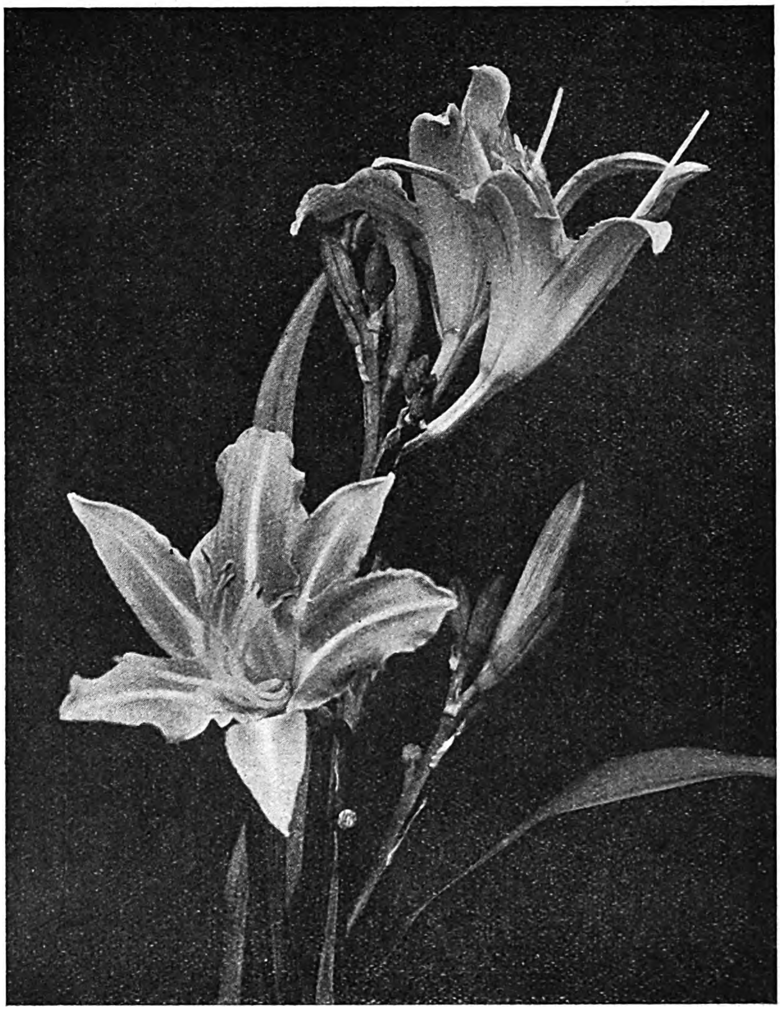

FIG. 28.—HEMEROCALLIS MARGARET PERRY.
(One of the newer Day Lilies.)

HOME CORRESPONDENCE.

The Colours of Flowers.—Referring to the "Home Correspondence" column in your issue of January 5, p. 16, I agree with your correspondent, *A Roman Reader*, that no colour chart can take the place of ordinary verbal colour description, and it was not intended to do so, but to supplement it. Colour terms such as your correspondent suggests, "Gentian-blue," "Mulberry-red," etc., are used by Mr. Ernst Benary throughout his catalogue which is sent out with his colour table, and they form a rough guide as to the tints of the flowers listed; but your correspondent is surely too sanguine when suggesting that twenty-five colour terms of this nature would suffice. A larger number than this is required to describe the various shades of red alone. Such a colour chart would certainly serve as a useful guide to those who have to draw up the descriptions of the tints of flowers they offer for sale. The various colours are not like the notes of a piano—each giving a distinct sound, separated from each other by tones or semi-tones, but merge imperceptibly into one another like the tones of a violin may do. The difficulty is to know when such a tint as a cold violet may be termed blue, and so on. There is no excuse for naming a full purple blossom ultramarine, but when flowers have to be described on the border line between two distinct colours of the spectrum, a reference to such a chart as that issued by Mr. Benary is of the greatest service. The chief hope that something may be done to secure accuracy and uniformity in colour description lies in the fact that the matter is one that is put down for consideration at the International Horticultural Conference to be held next year in London. Such uniformity can only be attained by the agreement of the leading horticulturists throughout the world. *H. H. Warner.*

Gardeners' Pay and Status.—With a view to a possible discussion regarding the general low rate of pay, and therefore, the equally low status which obtains in the gardening profession to-day, it would be enlightening to hear the opinions of your readers in this direction, and of any suggestions they may put forward by way of remedy. I would also be very glad to learn the opinion of your more experienced readers regarding the prospects that an ambitious young man might expect from following the gardening profession to-day. Up to the present, I have seen and heard much to discourage one. *R C.*

FRUIT GARDEN.

THE ROOT-STOCK PROBLEM IN APPLE-GROWING.

Your correspondent, Mr. H. Howard Grace, writing under the above title in your issue of December 29, 1928 (Vol. LXXXIV, p. 510), raises several points with reference to Apple-growing.

In the first place he asks what direct influence the experiments which have taken place on the question of root-stocks will have on Apple-growing generally throughout the country? This is difficult to answer, but it may be stated definitely that the knowledge now available will greatly encourage the development of the industry. It is, however, only one reason among many which is and will be giving great impetus to Apple culture.

Mr. Grace gives it as his opinion that it would be rash for anyone to speculate largely on a big planting scheme during these times of agricultural depression. It is strange that he should take this view. I contend it is one of the strongest arguments in favour of planting large acreages of fruit trees. Many farmers with fruit orchards—I refer to those who grow good fruits—have cause to be satisfied with this side of their farming activities.

I submit, also, he is making a mistake with reference to foreign competition spoiling the prices for home-grown produce. To prove this, I would suggest that, if he has good samples of any popular market Apple, such as Bramley's Seedling, Newton Wonder, Lane's Prince Albert or Cox's Orange Pippin, he should send them to a good salesman at any of the leading markets, either in the provinces or London, and I shall be surprised if his sales returns are not higher than those being obtained for similar varieties from abroad.

All that is necessary for the home-grower to do, is to grow a much higher proportion of first grade fruits than has been done in the past. The fact that we import millions of pounds worth every year, is proof that there is a market here. The consumption of fruits is increasing annually, and it only needs an improvement in trade generally to bring about a big boom in the fruit trade. The Apple is the most important of all fruits, and is not now looked upon as a luxury, but as a necessity, by all classes.

With regard to the grading and packing, over which a great deal of ink has been spilled, to say nothing about oratory, which would have vied with that at a political bye-election—it is now admitted that the English grower has nothing to learn from overseas. If one wished to criticise it would be that the advice to grade and pack better was given much in the same way as putting the cart before the horse, or, in other words, before there were many first grade fruits to pack. The lesson is now being learned, and first grade fruits are now produced annually in much larger proportion than of yore. Grading and packing are easy and pleasant occupations if one has plenty of good fruits to handle, but an expensive and almost impossible one with inferior quality fruits.

To summarise, I suggest that a knowledge of the root-stock problem is only one of many factors—I cannot go into them now—which must be taken into account when the question of Apple-growing commercially is considered, but if all are duly considered and intelligently acted upon, the English grower need have no fear of the disposal of his fruits in competition with those from overseas. *Arthur J. Cobb, University of Reading.*

AUTUMN-FRUITING RASPBERRIES.

Autumn-fruiting Raspberries deserve greater popularity than they at present enjoy, for once they find a place in the fruit garden it is rarely, if ever, they are supplanted. One or two summer-fruiting varieties of Raspberries also produce something of a crop during the autumn, but it is better, if late fruits are desired, to grow those kinds which are known to be autumn-fruiting, as very heavy crops may be obtained from some of these. As a rule, late-fruiting kinds do not need staking, but the treatment with regard to pruning is different from that needed by the earlier fruiting kinds.

Planting may be carried out at the same time as for other fruits, that is, during the autumn or the spring. Autumn planting is the most suitable for these varieties, as the canes become well established, and produce crops by the following autumn. They should, in any case, be cut down close to the ground during February, as it is on the ends of the growths produced during the summer that the fruits are borne.

Among the best of the autumn-fruiting Raspberries is the Hailsham, which is also known as the Hailsham-berry. It is a heavy cropping variety, producing fruits of large size, sweet, and red in colour. Another excellent variety is Merveille de Rouge, which also produces very large and sweet fruits. November Abundance is a late variety of the autumn-fruiting sorts. As its name implies, it bears fruits until November, and, like those mentioned above, it is a very good cropper, the flavour of the fruits being excellent.

Probably the latest of the autumn-fruiting Raspberries is Surprise d'Automne, which originated on the Continent. It produces fruits which are round in shape, large, and of fine flavour, and is well worth a place in the plantation.

For some reason yellow Raspberries have not found great favour, whether summer or autumn-fruiting. As with White Currants, there is not so keen a demand for yellow Raspberries commercially as for the red kinds. Yet there are varieties which, in point of quality and cropping, are able to hold their own with the more popular red sorts, and as the fruits are attractive in appearance and richly flavoured, they might well be grown more in private gardens for providing dessert fruits. *J. W. Morton.*

PROTECTING FRUIT TREES FROM RABBITS.

In your issue of December 22, 1928 (p. 497), Mr. Morton gives some useful hints on the protecting of trees from rabbits. So much damage is sometimes done by these animals, particularly in frosty weather, that further notes on the subject may be welcome, particularly from one who has had, perforce, to give some attention to the matter. It rather surprised me to find that Mr. Morton considered the surrounding of the plantation the most effective protection. I have seen many plantations so wired, but few were rabbit-proof for long. Ordinary three feet wire-netting is useless, for rabbits quickly learn how to run up it; they will also burrow underneath it, even when it is buried. A two-inch mesh is too large as it admits young rabbits. I consider the wiring of each stem quite the most effective, as well as often the cheapest method. The mesh should not be larger than one inch, and each cage should be made large enough to be clear of the bark. If it does touch, it will soon be found that rabbits will take bites from the bark between the meshes, at least, I can vouch for it that the Doddington breed will.

Where wiring is not possible, and untidiness is not unbearable, it is a good plan to leave any branches which are pruned off lying on the ground all the winter. It will be found that the rabbits will gnaw these in preference to the vertical stems, which are less handy for them.

Generally, a tree is safe from attack when it has a stem several years old, but it is hardly safe to rely on this immunity. I shifted some large trees from an unwired area into new ground, and they were attacked immediately. A long spell of frost would very likely render it necessary to protect the largest trees in this district, for during last winter the young growths of Chestnut trees in the woods were skinned over acres of woodland. I had left my prunings lying, and when I observed how cleanly the bark had been gnawed from them, I rejoiced in my good fortune. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

VEGETABLE GARDEN.

FORCING EARLY POTATOS.

With the arrival of the New Year, the question of growing early Potatos under glass will need attention.

To have new Potatos so early as possible, tubers should be put into boxes without delay. The boxing of Potato "seed" should be regarded as work of importance, and should not be done in a slipshod manner, for the production of an early crop depends largely upon the condition of the tubers when set. The tubers should be carefully selected, and should be fairly uniform in shape and size. Each should be greened thoroughly by exposure to light, standing them closely together in shallow boxes, with the crown eyes uppermost, so that they will not fall when the boxes are moved about. As the boxes are filled, they should be removed to a warm greenhouse and shaded for a few days. This should induce the sprouts to form quickly, but so soon as the sprouts are fairly started, expose them to the full light so that they grow slowly and become brown and hard. Although some growers advocate producing long sprouts, experience has proved that those about one inch in length are quite long enough, and on no account should the sprouts be of the white, callow kind, for sprouts of this description are liable to be attacked with the disease Macrosporium Solani, while in the sprouting box. This disease generally appears when the tubers are placed in layers instead of upright, and kept in the dark too long.

Early in February, the tubers will be ready for potting into small pots or planting out in the greenhouse border. The material used in either case should be of a leafy nature.

When planting them in borders, small trenches six inches deep and eight inches wide should be made the whole length of the border, and the tubers (whole) planted nine inches apart. Whether the tubers are potted or planted out, they should be covered sufficiently. No earthing up will be necessary.

Previous to planting, each tuber should be dipped in a mixture of freshly-slaked lime and flowers of sulphur in equal parts, the preparation having been made one or two days beforehand. This acts as a preventive agent, and thus a healthy crop is assured.

While the Potatos are making growth, a moist atmosphere and an even temperature of 60° to 65° should be maintained. *G. B.*

PUBLIC PARKS AND GARDENS.

The Lowestoft Town Council will make application for sanction to borrow £11,000 for the development of Nicholas Everitt Park, recently presented to the town by Mr. H. Hollingsworth.

The Radcliffe Urban District Council has agreed to provide recreation grounds in three wards of the town at a total estimated cost of £14,000.

The Redcar Town Council has received sanction to lay-out Locke Park at a cost of £2,500.

The Hull Parks Committee has decided to provide a municipal golf course costing £23,000.

The Consett Urban District Council is making application to the Ministry of Health for sanction to borrow £500 for the purchase of land for a recreation ground.

The Heston and Isleworth Urban District Council has agreed to purchase, for a sum of £3,500, a site of eight acres adjoining Hounslow Barracks, for a public open space.

The Swansea Town Council is recommended to provide a recreation ground in Brynmelyn ward.

SOCIETIES.

ROYAL HORTICULTURAL.

January 15.—As is well-known, the first fixture for the year of the Royal Horticultural Society was abandoned on account of the sudden death of the President, so that the first meeting of the year was held at an unusually late date. With the aid of various exhibits of sundries, several of them quite attractively set out, the Hall in Vincent Square was filled on the present occasion. Orchids were freely shown, and in addition to a collection of very fine Cypripediums, the general collections were of great merit. The Orchid Committee recommended two First Class Certificates and three Awards of Merit to novelties. The chief exhibits before the Floral Committee were miscellaneous stove and greenhouse plants, including particularly good Carnations, early-flowering shrubs and border flowers, and dwarf Conifers of the type valued for the rock garden. The Floral Committee recommended three Awards of Merit to novelties. Although the Fruit and Vegetable Committee had no novelty of moment, there was a magnificent collection of vegetables and two excellent collections of Apples in the hall.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Stuart H. Low, Mr. E. R. Ashton, Mr. T. Armstrong, Mr. J. Cowan, Mr. A. McBean, Mr. Lionel de Rothschild, Mr. Frederick Hanbury, Mr. S. W. Flory, Mr. H. G. Alexander, Mr. T. W. Taylor, Mr. Fred. K. Sander, Mr. A. Dye, Mr. Charles H. Curtis, Mr. J. E. Shill and Dr. G. R. Machado, of Jamaica, a visitor.

First Class Certificates.

Cymbidium Albania (*albanensis* × *Alexanderi*).—A very beautiful addition to a fine class of Orchids. It is of fine colouring, the sepals and petals being a lovely soft shade of rose-pink with slightly darker veins, while the lip is bright rose-red, with numerous small spots and veins of deep velvety red. Shown by Messrs. J. and A. McBean.

Cypripedium Strombole (*Nubia* × *Gaston Bulteel*).—A very fine hybrid, with a bold, wide, rounded dorsal sepal of deep rose colour, with darker reddish-purple shading over the centre. Petals and lip brown and green. The whole flower is lustrous. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Awards of Merit.

Cypripedium Littlecot (*J. M. Black* × *Perseus Alpha*).—In this hybrid, the white, green-based dorsal sepal is very heavily blotched with blackish-purple. The petals and lip are glossy green and brown, the former carrying a few blackish spots. Shown by Messrs. Black and Flory.

Cypripedium Windrush var. Mentieth (*Zena* × *Memoria F. M. Ogilvie var. The King.*)—A bold hybrid, of broad and rounded form. The dorsal sepal is a trifle hooded, white, with a green base and heavy spottings of blackish-purple, the spottings being smallest and palest on the white area. The wide petals are rich brown on the upper half and green below. Lip brown and green. Shown by Messrs. J. and A. McBean.

Cypripedium Jungfrau, Brockhurst var.—A fine Cypripedium of bold, upstanding shape, and with a very wide, white, green-based dorsal sepal, with a few pale purple spots over the centre. The petals and lip are pale green. Shown by Fred. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead.

Groups.

A bank of beautiful Orchids was arranged by Messrs. J. and A. McBean, who had a generous display of Odontoglossums, including forms of O. crispum, O. c. xanthotes, O. Diana, O. majesticum, O. citrinum, the fine O. Mirum and the graceful O. Phoebe. Cymbidiums were also well represented, and there were good examples of Laelia anceps in variety, Vanda coerulea, Cattleya Maggie Raphael alba, Laelio-Cattleya Sunbelle, Vanda Amesiana, Odontiodas and Cypripediums, these last including the charming C. Boltonii and the big, rounded C. Windrush, of fine breadth and colour.

Messrs. Charlesworth and Co. made a very fine contribution, their large group being arranged in graceful fashion, and containing a fine selection of Odontoglossums, Odontiodas and Calanthes. These last were represented by C. Bryan and C. William Murray. A few outstanding Odontoglossums were O. crispum xanthotes, O. Amabilicity, O. Llewellyn var. Colossus, O. Toreador, O. Britannia and O. muralis, while other good things were Vuylstekeara Brewii, Cattleya Thais, Oncidium splendens, O. cheirophorum, Masdevallia tovarensis and a selection of Cypripediums.

S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton, put up a bright exhibit wherein figured Angraecum sesquipedale, Epidendrum vitellinum majus, a lovely specimen of Oncidium cheirophorum, O. bicallosum, and O. ornithorhynchum. Odontoglossum Penelope, Brownlands variety, was a conspicuous plant, while other interesting kinds included Maxillaria Hubschii, Odontoglossum bictonense, with thirty-six flowers, Gomeza planipes and Cymbidium Tracyanum.

A group of superb Cypripediums was staged by Miss A. B. Moore (gr. Mr. W. H. Page), Chardwar, Bourton-on-the-Water. These were marvellous Cypripediums of wonderful size, shape and colour. In a grand lot, a few outstanding sorts were C. Chrysostom var. Mary Crawford, C. Mrs. Ely var. Derrick, C. Chardmoore var. W. H. Page, C. Gwen Hannen var. Field-Marshal, C. Albert Mercier, C. Sir Trevor var. Chinchinjunga, C. Magna var. Fred Sander, and C. Prince Albert var. Mecca.

Messrs. Cowan and Co.'s group consisted chiefly of bold Cypripediums, with a margin of good examples of Masdevallia Schröderiana. A few leading Cypripediums were C. Ponticus, C. Memoria F. M. Ogilvie var. The Premier, C. Corsair, Holford's variety, C. Marcus, C. Nydia, C. Niobe-Leeanum and C. Golden Wren.

Angraecum superbum was a striking plant in the group arranged by Messrs. Sanders. Vanda Amesiana, the curious hybrid Odontoglossum Longowoyi, Oncidium splendens, and many good forms of Lycaste Skinneri attracted attention, as did the yellow and carmine Laelio-Cattleya Mrs. Medo. Cymbidiums, Cypripediums and Miltonias were also included.

Mr. J. Evans put up a very pleasing exhibit of Cypripediums associated with Masdevallia Schröderiana and Oncidium cheirophorum. A few of the finest Cypripediums were C. Mrs. Ely, C. Major Hanbury Carlile, C. Madame Jules Hye and C. Alcibiades var. Illustris with five splendid flowers.

Messrs. H. G. Alexander showed Cypripedium Imperator, Westonbirt var., C. Macaw, C. Perseus, C. Otus, the pretty C. Juliet, and the colourful C. Baldur, Holford's variety. Cypripediums were well shown by Messrs. J. Cypher and Sons, whose group contained attractive examples of C. Corsair, C. Lathamianum aureum, C. Pixie, C. Ballet Girl, C. Cupid and C. Hercules.

Messrs. Black and Flory, Messrs. Armstrong and Brown, Mr. Robert Paterson, and Mr. Fred. Hanbury, all showed a few Orchids.

Floral Committee.

Present: Section A.—Mr. J. F. McLeod (in the chair), Mr. R. Findlay, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. M. C. Allwood, Mr. J. T. West, Mr. W. B. Gingell, Mr. James B. Riding, Mr. D. B. Crane, Mr. C. F. Langdon, Mr. Courtney Page, Mr. B. R. Long, Mr. E. R. Janes and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Gerald W. E. Loder (in the chair), Mr. G. Reuthe, Mr. Reginald Cory, Mr. Charles T. Musgrave, Mr. F. G. Preston, Mr. L. R. Russell, Mr. Mark Fenwick, Lady Beatrix Stanley, Sir William Lawrence, Bart., Mr. E. H. Wilding, Mr. A. Bedford, Mr. E. A. Bowles, Mr. T. Hay, Mr. Clarence Elliott, Mr. R. C. Notcutt, Mr. R. W. Wallace and Mr. N. K. Gould, Secretary.

Awards of Merit.

Carnation Thomas Ives.—A very large greenhouse variety made up of broad, stout, undulating petals of glowing cerise colour with a rosy reverse. The illustration in *The Gardeners' Chronicle* for December 1, last, gives a good impression of the form of this showy variety. Shown by Messrs. Stuart Low and Co.

Chrysanthemum New Year.—This is a very attractive Single variety of medium size, with two rows of ray florets. The colour is golden amber, with a faint rosy margin and a definite yellow zone. Shown by Mr. H. Shoesmith, junr.

Erica australis var. Mr. Robert.—This pure white form of the well-known Erica australis was found in the mountains of southern Spain, near Algeciras, in 1912, by the late Lieut. Robert Williams (son of Mr. J. C. Williams, of Caerhays Castle, Cornwall), who was killed in the late war. This white variety flowers rather earlier than the species, and has a more compact habit. Shown by Messrs. Robert Veitch and Son.

Groups.

In a very attractive group of miscellaneous stove and greenhouse plants, Messrs. L. R. Russell, Ltd., included well-flowered plants of Epiphyllum Makoyanum, Strelitzia Reginae, various Bromeliads and Camellias. Messrs. Stuart Low and Co. grouped tall specimens of Acacia Baileyana, A. albens and other Mimosas, with Camellias, Acokanthera (Toxicophlaea) spectabilis and small plants of the golden-leaved Oleander. A large, floor group of Euphorbia (Poinsettia) pulcherrima was contributed by the Hon. Vicary Gibbs (gr. Mr. Edwin Beckett), Aldenham House, Elstree. In addition to the scarlet species there were many plants of the white and the pale rose-coloured varieties.

A very interesting exhibit of early-flowering shrubs was made by Messrs. Robert Veitch and Son. They had generous branches of Hamamelis mollis, H. arborea, Garrya elliptica, Grevillea rosmarinifolius, and Parrotia persica, with dwarf plants of Daphne japonica and various Camellias. Mr. George G. Whitelegg arranged a very good collection of dwarf Conifers, including the Irish Juniper, various species of Pines, Cupressus and Taxus, and also had heavily-berried branches of Pernettya mucronata. Mr. Stephen Sim also had shapely little Irish Junipers and other Conifers, with the bright yellow Primula Barrowby Gem. Messrs. Patrick staged various interesting hardy shrubs including Erica mediterranea, shrubby Veronicas, Viburnum Tinus, Berberises and Conifers. Mr. J. Klinkert had a collection of shapely topiary specimens in evergreen Box.

Messrs. Barr and Sons showed a pretty collection of early border flowers, which included Galanthus byzantinus, Crocus reticulatus, Iris alata, and an excellent strain of blue Primroses. In the background there were sprays of brightly coloured Eleagnus pungens aurea and, at one end of the group, they had a dozen or more plants of Lachenalia pendula of rich colour.

Especially good greenhouse Carnations were shown. Messrs. C. Engelmann, Ltd., included such valuable Fancy varieties as Katja, Circe Improved and Moggy. Messrs. Stuart Low and Co. had a large vase of the vividly coloured Thomas Ives, and also the pink Eileen Low in quantity. Messrs. Allwood Bros. staged, in Wivelsfield Buttercup and the pale salmon Guy Allwood, two of their 1929 varieties, and had a large selection of Dianthus Allwoodii.

There was a large number of exhibits of paintings and garden plans, horticultural sundries and garden furniture. Among exhibitors of paintings were Miss Winifred Walker, whose picture of "Flowers of Southern California" attracted considerable attention; Mrs. Ellenor S. Ough, Miss Agnes Strickland, Miss Edith A. Andrews, Miss Julia Fielding, Miss E. Frances Drake, Miss Alice F. Wilkinson, Mrs. M. Townsend, Miss Marion Broom and Miss Ellen Warrington. Garden designs were displayed by Messrs. S. and G. Paris, Mr. Percy S. Cane and Messrs. Bakers;

Messrs. **Boulton and Paul, Ltd.**, had examples of glasshouses and garden frames, and there were numerous garden baskets, wheel-barrows, etc., from the Lord Roberts Memorial Workshops. Summer-houses and garden ornaments were exhibited by Mr. C. White, while there was also an exhibit of the " Noelite " garden paving tiles.

Fruit and Vegetable Committee.

Present: Mr. C. G. A. Nix (in the chair), Mr. H. S. Rivers, Mr. J. Basham, Mr. T. Pateman, Mr. A. W. Metcalfe, Mr. W. F. Giles, Mr. J. Wilson, Mr. H. Prince, Mr. E. Beckett, Mr. A. Poupart, Mr. W. H. Divers, Mr. J. Cheal, Mr. E. A. Bunyard and Mr. A. N. Rawes, Secretary.

Several seedling Apples were shown before this Committee, which expressed the wish to see a tree of a seedling with large, culinary fruits of the Lane's Prince Albert type, next autumn. This seedling was shown by Mr. G. Wratten, Bembridge, Isle of Wight.

Groups.

At this season of the year one would hardly expect to see so fine and representative an exhibit of vegetables and salads as that set up by Messrs. Sutton and Sons. There were magnificent heads of Broccoli Sutton's Early Roscoff, pillars of fine " buttons " of Brussels Sprouts Sutton's Fillbasket, Dwarf Gem and Matchless; Carrots, both long and stump-rooted; Mushrooms, Celery, Kale, Savoys, Marrows, Parsnips, Beet, Onions and Potatos, all in several varieties, while among salads were Endive, Cress, Chilies, Oxalis crenata tubers, Cucumbers, various types of salad Potatos, Lettuce, Dandelion, Chicory, and Stachys tuberifera. A grand display of splendidly grown and excellently staged produce.

Two splendid collections of Apples were staged at this meeting by Messrs. George Bunyard and Co. and Messrs. J. Cheal and Sons, Ltd., respectively. In both instances the fruits were richly coloured and in good condition.

Messrs. George Bunyard and Co., showed exceptionally good examples of Lord Derby, Ontario, Allington Pippin, Ellison's Orange, American Mother, Cox's Orange Pippin, Emperor Alexander, Hormead's Pearmain, Court Pendu Plat, Orlean's Reinette, May Queen, Lord Hindlip and Lady Henniker.

In the comprehensive collection of Apples staged by Messrs. J. Cheal and Sons, Ltd., we noticed large baskets of grand specimens of Prince Albert, Beauty of Kent, Annie Elizabeth, Newton Wonder, Encore, Blenheim Pippin and Crimson Bramley; while other varieties well represented were Brownlee's Russet, Rival, Chelmsford Wonder, Lady Henniker, Wagener, Christmas Pearmain, Cornish Aromatic, Crawley Beauty, King George V, Ellison's Orange, Sir John Thornycroft, Charles Ross and American Mother, to mention but a few.

GUILDFORD AND DISTRICT GARDENERS'.

In furtherance of the educational work carried out by this Association, two meetings for lectures were held during December, 1928, one on the 10th and the other on the 31st.

On the first occasion, three members read short papers on subjects with which they were well qualified to deal. Mr. A. J. Joy dealt with Cyclamens, Mr. J. Mackay, The Hill, Witley, with Orchids, and Mr. T. Newman, Tangley Place, lectured on the cultivation of Onions. Although comparatively short, the papers were full of valuable cultural details. Mr. Mackay, to illustrate his lecture, displayed a number of splendid Orchid blooms. The Onion crop in the Guildford district was very poor last season owing, chiefly, to the ravages of the Onion maggot, therefore considerable interest was aroused by Mr. Newman's lecture. He stated that the only Onion fly preventive he ever used was sulphate of ammonia applied twice during the season, when the seedlings were just above the soil, and again a fortnight or three weeks later. Autumn-sown plants, when replanted, also receive a sprinkling.

On December 31, the attendance was below the average. Mr. Taylor, of Messrs. Sutton and Sons, Reading, was the lecturer. His subject being " Salads all the year round."

In order to produce such a supply, Mr. Taylor stated that among the indispensable subjects, were Beetroot, Chives, Corn Salad, Chicory, Celery, Celeriac, Mustard and Cress, Cucumbers, Curled and Batavian Endive, Lettuce, Onion, Radish, Winter Radish, Tomato, Sorrel and America Cress.

He gave hints on the best varieties, and how to cultivate them, and illustrated his lecture with lantern slides, some of them beautifully coloured.

The next lecture will be on Tuesday, January 22, when Mr. Lavender, of Messrs. James Carter and Co., will speak on "Annuals." A whist drive will be held on January 23, and a New Year's social gathering on the 30th inst.

READING GARDENERS'.

The annual meeting of the above Association was held in the Abbey Hall on December 7, 1928, and was presided over by Mr. H. Reeves, Chairman of Committee.

The statement of accounts and annual report, as read by the Hon. Treasurer and Hon. Secretary, respectively, showed that the Association was in a most flourishing condition. The membership has been well maintained and the financial position was very sound. The membership totals 310, and the balance in hand came to £113.

The following officers were elected for 1929 :—President, Mr. Frank E. Moring; Vice-Presidents, Mr. Leonard Sutton, Mr. Alderman F. B. Parfitt, Mr. E. P. Foquett Sutton; Hon. Treasurer, Mr. A. H. Leaver; Chairman, Mr. W. Broomfield; Vice-Chairman, Mr. E. Blackwell; Hon. Secretary, Mr. H. G. Cox (80, Hamilton Road, Reading); and Hon. Assistant Secretary, Mr. E. J. Dove.

The Committee elected is composed of Messrs. C. Cook, H. H. Fulker, C. Moulton, P. H. Reed, H. Reeves, and F. Townsend (Reading); G. Carter (Mapledurham); M. Goddard (Bear Wood); W. Chislett (Bill Hill); A. W. Gower (Calcot); F. J. Green (Aldermaston); H. H. Cook and J. R. Lloyd (Shinfield); C. J. Howlett and C. S. Clacy (Earley); J. Young and T. Butcher (Norringham); Dow (Sulhamstead); J. Wynn (Checkenden), and H. Goodchild (Caversham).

NORTH OF ENGLAND HORTICULTURAL.

This Society has arranged with the Harrogate Corporation to hold its spring show in the Winter Gardens—the old meeting place—on April 3 and 4 (the Wednesday and Thursday of Easter week), when, as the town is always full of visitors at that period, good business may be looked forward to. As the space available is strictly limited, intending exhibitors should apply at once to the Acting Hon. Secretary for space required, and at the same time state the nature of their exhibit. Arrangements for the autumn show are not yet completed, but will be notified so soon as possible.

Mr. W. A. Taylor, Gresford, Harrogate, is the Acting Hon. Secretary.

Obituary.

Thomas Jones.—We learn with regret of the death of Mr. Thomas Jones, following a long illness. Many of our older readers will remember Mr. Jones as gardener at Elvetham Park, where he served the fifth and sixth Barons Calthorpe in the 'seventies and 'eighties of last century. After leaving Elvetham, he had a varied and disappointing experience, in nursery work, as a market gardener, and as a hotel proprietor; the war period treated him badly, and then came illness and suffering that ended in his death on December 17 last. The remains were placed in the grave of his wife, in Fleet Churchyard, Hampshire, on December 22.

ANSWERS TO CORRESPONDENTS.

Hyacinth Bulbs Diseased.—*W. S.* The Hyacinth bulbs were attacked by (1) a fungus rot of the basal plate, due to Fusarium; (2) bulb mite, and (3) Collembola. The affected bulbs should be removed at once and burnt. There is no remedy against this Fusarium rot; the mites and Collembola are secondary causes of the internal decay. Soil in which diseased bulbs have been grown should be sterilised.

Leaves of Carnation Curling.—*T. S. C.* The Carnation cuttings show clearly that the plants have received a decided check in growth, the result of which is the production of curled foliage at the end of the shoots. It is not uncommon to find this phenomenon occurring on plants during the winter months. Draughts and sudden falls in temperature cause the trouble. The plants should grow satisfactorily in the spring. Careful attention should be paid to ventilation and firing during such weather as we are at present experiencing, *i.e.*, with great variations in temperature from day to day.

Licences for Gardeners and Under-Gardeners.—*W. S.* Under the Inland Revenue Act 1869, a licence is required for all " gardeners " and " under-gardeners " solely employed by a private employer. Whether a workman employed all his time in working in a garden is or is not a gardener or under-gardener or a person employed in any compacity involving the duties of a gardener or under-gardener within the Act, is a question of fact to be decided by the Justices on the evidence submitted to them. The mere employment in a garden of a man doing work which a single-handed gardener would have to do, does not necessarily make the man a gardener, and Justices, in deciding the point, are entitled to consider whether or not the work done by him is work for the proper execution of which skill in gardening is required.

Names of Plants.—*A. P., Reigate.* 1, Veltheimia viridiflora; 2, probably a Cypripedium villosum hybrid; 3, Cryptomeria japonica elegans; 4, Cypripedium villosum; 5, Cupressus Lawsonia albo-spica; 6, 7, 8 and 9, Calanthes (flowers badly damaged in post and not recognised); 10, Cupressus pisifera squarrosa; 11, Juniperus communis; 12, Cupressus obtusa; 14, Cupressus lusitanica. —*G.* 11, Euonymus japonicus var. albo-marginatus; 12, Viburnum Tinus (Laurustinus); 13, Hedera colchica var. variegata; 14, Hedera colchica var. amurensis; 15, Hedera colchica var. variegata; 16, Osmunda regalis; 17, Helleborus foetidus; 18, Helleborus sp. The specimens were all so scrappy that definite identification was difficult.

Securing Seeds of Abies.—*H. R.* If you keep the cone in a warm atmosphere the scales will soon come apart and the seeds fall out. The seeds should germinate satisfactorily if sown in the open, but as you will have only a few, we would advise you to sow them in a pot, cover them with a pane of glass, and place them under a north wall.

Strawberries Failing.—*A. S.* So far as could be determined, the Strawberry plant is free from attack of any pathogenic organism, and there is no sign of attack by insects or other animal. The rootstock and crown were healthy—the suggestion is that the trouble is due to the deterioration of the stock from which the runners were obtained. Send a specimen—a whole plant—during the active growing season if the trouble continues.

On Bolting.

All field and garden plants derived from species of biennial habit. show, to a greater or less degree, a tendency to rush their development so as to bring it to the flowering stage within one season. The expression of this aptitude of biennials to behave as annuals, known as bolting, is manifestly influenced by seasonal conditions. Last year, for example, bolting was well marked among Beet, Onion, Leek and other garden and field crops. The bolting of a crop is, or may be, the occasion of serious loss, for, inasmuch as growth of flowering stem tends to deplete the stores of food material which would otherwise be laid down and conserved in the "root," these stores in the bolting plant will tend to become smaller and of lessened food value. It is a good many years since the late Dr. William Bateson turned his attention to the subject of bolting, and although he never published the results of his investigations, it was known to those associated with his work that he had accumulated a large amount of valuable information on the subject. This information has now been made available in a paper* published by Sir Daniel Hall, who, as our readers know, succeeded Bateson as Director of the John Innes Horticultural Institution. Bateson's work related chiefly to the cultivated forms of Beta maritima—Mangold, Sugar Beet and Garden Beet, and its object was to ascertain to what extent bolting is due to inherited characteristics as opposed to climatic influences. That climatic conditions play a large part in encouraging bolting is easily demonstrated. Early sowing, or a check to growth, may raise the percentage of "bolters" far beyond that which obtains when the plants are sown later and suffer no check in growth. For example, Bateson showed that if Beet or Mangold are sown under glass early in the year and are transplanted into the open about April, some seventy per cent. of the plants will bolt. Starting from the fact that even under such conditions so favourable to bolting some thirty per cent. of the plants resist the temptation, he proceeded to investigate the genetical character of the non-bolters. By selection from the latter, continued for two or three generations, he was able to isolate strains which show no bolting under ordinary field or garden conditions. It therefore follows that climatic conditions are not the only predisposing cause of bolting, but that hereditary characteristics also play a part. From a practical point of view, these conclusions are, of course, of great importance, for they pave the way by following which our seedsmen may, in course of time, provide us with strains of garden plants which behave as true biennials and refuse to try to become annuals, even when prompted so to do by seasonal conditions. As Sir Daniel Hall points out in the summary to his interesting paper, Bateson recognised that resistance to bolting does not depend on a single factor, but on several. This, no doubt, makes the task of selecting non-bolting strains somewhat more arduous, nevertheless, it is one which will probably prove well within the powers of practical plant breeders.

Lists of R.H.S. Awards.—The Royal Horticultural Society has recently published the official lists of awards made by it to Orchids, decorative plants, fruits and vegetables, during the years 1925 and 1926. The list of awards to Orchids (a separate publication) supplements those published by the Society in 1916 and 1926, while the list of awards to decorative plants (except Orchids), fruits and vegetables, is issued as a supplement to that giving awards up to 1924. For reference purposes, these lists (edited by Mr. Fred. J. Chittenden) are very useful, and may be obtained from the Society's office, Vincent Square, Westminster, S.W.1, price 1s. each.

The Ideal Park.—At the meeting of the Association of Parks and Botanic Gardens Superintendents (London Branch), to be held in the Lecture Room, at the R.H.S. Hall, Vincent Square, London, on Tuesday next, January 29, Mr. A. J. Ashmore (Chairman of the London Branch of the Association) will deliver a lecture entitled "The Ideal Park." The chair will be taken by Mr. H. Prentice, at 7 p.m. prompt. This lecture should prove of great interest to all parks representatives and horticulturists generally, to whom a hearty invitation is extended.

Vegetable Cultivation.—A new volume, *The Cultivation of Vegetables* (Sectional Vol. No. 12, price 1s. 3d. post free, obtainable from the Ministry of Agriculture, 10, Whitehall Place, S.W.1), has been added to the Ministry's series of sectional volumes of collected leaflets. This is a booklet of commercial vegetable production written specially for market growers. The methods of production described are those which have proved successful for market growers and the varieties suggested are known to be suitable for most markets. At the same time, the volume contains very sound advice for the private grower or allotment holder. The information contained in the leaflets has been condensed so far as possible, and simple language has been used. Several of the leaflets have been specially written for the volume, *e.g.*, those on Shallots, Leeks, Seakale, Rhubarb and Salad vegetables. Other vegetables dealt with include Cabbages and Savoys, Brussels Sprouts, Peas and Beans, the Vegetable Marrow, Parsnips, Onions, Mushrooms, Asparagus, Tomatos, Cucumbers and Watercress. In addition, there are leaflets on the general cropping, manuring and cultivation of allotments (with chart), the manuring of vegetable crops, and practical soil sterilisation by heat for glasshouse crops. Diseases and pests of Tomatos and Cucumbers are touched upon, and methods of marketing are also dealt with.

New Park for Stanmore, Middlesex.—A people's park, five-and-a-half acres in extent, is to be purchased at Stanmore Hill, Middlesex, at a cost of £1,550. Of this sum £1,000 is being raised by voluntary contributions from the people of Stanmore, and the remainder will be provided by the Hendon Rural District Council. A local resident, Mr. Samuel Wallrock—an enthusiastic horticulturist, whose successes at Watford were recorded in our issue of November 24, 1928—has undertaken to be responsible for the laying out of the grounds, after which they will be taken over and maintained by the Rural Council.

Developments in Peasholm Park, Scarborough.—The Borough Council of Scarborough has adopted a recommendation of its Parks Committee to construct a Japanese pagoda on the highest part of the island in the lake at Peasholm Park, the building to be in keeping with the Japanese character of other buildings around the lake. A bridge is to span the water which will be made to form cascades ere it reaches the lake, and Japanese stone lanterns will be placed at suitable points on ledges of rock. There is also a proposal to provide artificial lighting so that the whole of these new features may be illuminated after dark. Later, the area around the pagoda will be laid out and planted as a Japanese tea-garden.

Dutch Nurserymen and Spain.—An exhibition of Dutch horticulture is being organised to take place in Madrid some time during the coming spring, probably in April. This interesting event will be a preliminary to the large exhibit which the Dutch hope to send to Barcelona for the great exhibition to be held there next year. The Dutch nurserymen take their occupation very seriously, and their participation in foreign exhibitions always has the effect of raising even higher than before, the general esteem in which their capabilities are held. The former close connection between Spain and the Netherlands makes this particular event especially interesting.

Abbey Wood, Woolwich.—We understand that an endeavour is being made by the Woolwich Borough Council and the Woolwich Regional Town Planning Advisory Committee, to secure the preservation of Abbey Wood, which covers an area of two-hundred-and-fifteen acres, and includes the ruins of Lessness Abbey, together with a group of ancient earthworks, as a public open space. The property at present belongs to several owners, but an option to acquire the whole area has, apparently, been obtained. It is estimated that £20,000 will be required to complete the purchase; the Woolwich Borough Council has agreed to give £1,000 and various other local authorities have been asked to subscribe, while it is proposed to form a representative Purchase Committee, which will issue an appeal for funds. The Abbey Wood area is composed of undulating land and commands a fine view of the Thames estuary, and although very little of Lessness Abbey now remains above ground, the extensive structures below ground are well preserved, and it is suggested that they could be unearthed and preserved under conditions which would safeguard them from deterioration.

Fluctuations in the Numbers of Rodents.—Mr. A. D. Middleton, Department of Zoology and Comparative Anatomy, University Museum, Oxford, writes:—It is a well-known fact that in some years the smaller rodents, notably mice and voles, swarm over large areas of country and become a serious nuisance to farmers, gardeners and others. It has been found that there is a good deal of regularity in the occurrence of these rodent years. Field voles in this country and lemmings in Norway and northern Canada swarm at intervals of a few years, and this is followed by a diminution in numbers which is apparently brought about by epidemic diseases. We are carrying on an investigation into these cycles, and are desirous of obtaining information on the subject from various parts of the country, in order that light may be thrown on their causes and preventive measures devised. The study of the epidemic diseases from which the rodents suffer is also of significance in connection with human and animal pathology. We should be greatly indebted to readers of *The Gardeners' Chronicle* for any information upon the following points :—(1) Any pronounced increase or decrease among field voles, squirrels, or other rodents ; together with dates, localities, etc. ; (2) any disease among rodents ; (3) any increase or decrease in numbers of birds of prey, and of stoats and weasels, in particular years.

---

* "Bateson's Experiments on Bolting in Sugar Beet and Mangolds," by Sir A. D. Hall, K.C.B., *Journal of Genetics*, Vol. XX, No. 2, Nov. 1928.

Sutton's Garden Calendar.—Among the several useful publications issued each year by Messrs. Sutton and Sons, of Reading, is a handy *Garden Calendar and Diary.* The garden calendar, in the form of "gardening reminders" for each month, occupies the front portion of the *Diary*, together with instructive articles dealing with annuals for greenhouse and conservatory cultivation ; Strawberry growing ; the making of lawns ; renovating old turf, and garden pests. There are useful lists of hardy annuals, classified according to colour, and of alpine plants which may be raised easily from seeds, together with much other useful data.

Tree-planting of Barnet By-pass Road.—On Saturday, January 19, Lord Ullswater planted the first tree on the Barnet by-pass road, under the scheme formulated by the Roads Beautifying Association. The tree, a Turkey Oak, was planted on a stretch of grassland which fringes the road in front of the Mote Mount Golf Club, Mill Hill, and it is hoped that in time the Barnet arterial road will be fringed with trees along its entire length, from Finchley Road to Welwyn Garden City.

Abnormal Rainfall in Bute.—According to the statistics furnished by Mr. John Davidson, gardener to Sir John Reid, Ardencraig, Rothesay, to the Meteorological Department in London, 1928 provided the highest rainfall recorded on the island of Bute since the observations were instituted 128 years ago. The total rainfall, which amounted to 72·58 inches, is 12·70 inches more than in 1927, and 23·54 inches above the average. January was the wettest month. Rain fell on thirty days, when 10·43 inches were registered, while October came next with 10·31 inches, and April was the driest month with 2·16 inches. To get anything approximating to last year's total, it is necessary to go back to 1811, when the rainfall was 71·37 inches. Rainy days in 1928 totalled 269, and the greatest fall in twenty-four hours was 1·35 inches, registered on November 23.

Unemployed Miners in the London Parks.—Over 200 unemployed miners have arrived in London for work in the Royal Parks, a sum of £200,000 having been voted by the House of Commons in December. It is intended that altogether 700 men shall be brought from the mining areas for this purpose. Some resentment having been expressed by the local unemployed at the miners being given this work, it is explained by the Ministry of Labour that the work is not essential, but has been undertaken solely for the purpose of absorbing the miners, and will be paid for out of the money specially allocated for their relief by the Government.

Legacies to Gardeners.—The late Mr. C. E. B. Young, of Daylesford, Kingham, Oxford, who died on September 22, 1928, left £200 to his head gardener, Mr. T. E. Ward.—The late Mr. C. S. Gray, of Rozel, St. John's Park, Ryde, who died on November 25, 1928, left £50 to his gardener, Mr. Henry Welsh.—The late Miss C. G. Trower, of Stansteadbury, Stanstead, Hertfordshire, who died on November 8, 1928, left an annuity of £20 to her gardener, Mr. Marrable.—The late Mr. John Smith, of Kewhurst, Little Common, Bexhill-on-Sea, who died on November 5, 1928, left £52 per annum to his gardener, Mr. James Law, for long and faithful service.

Acreage of Varieties of Potatos in Scotland, 1928.—The Department of Agriculture for Scotland intimates that thirty-six-and-a-half acres of Potatos of the variety Arran Banner were inspected and certified by them during the season 1928. It is regretted that owing to errors made by certain occupiers of farms in filling up the schedule for returns of varieties planted, the acreage of this variety was given in the table published by the Department on October 1, 1928, as eighty-one acres. Arran Banner was registered by the Department in the year 1927 as a new, immune, early maincrop variety.

Mr. A. Birkenshaw.—Among those of the "younger generation" who have gained distinction in the realm of horticulture is Mr. A. Birkenshaw, whose appointment as Superintendent of the Public Parks at Preston was announced recently. Mr. Birkenshaw joined the garden staff of the Royal Horticultural Society's Gardens at Wisley soon after the termination of the war, as a journeyman in the fruit houses. Upon leaving Wisley, where he had risen to the post of leading journeyman, he went to the Royal Botanic Gardens, Kew, and from there, in 1923, he moved to Manchester, having secured an engagement under the Manchester Parks Department. At Manchester, Mr. Birkenshaw's early training at Wisley, coupled with the further knowledge gained at Kew, stood him in good stead, for he was soon given a responsible position. He was appointed head of the Birchfields Park, a post which carried with it the superintendence of nine of the smaller open spaces of Manchester, and it was no doubt the masterly efficiency which he displayed in the exercise of his duties in this capacity, that secured for him the coveted post of Superintendent of the Preston Public Parks. Mr. Birkenshaw took over his new duties on the 2nd instant, and we wish him every success.

MR. A. BIRKENSHAW.

John Innes Centenary Conference.—On Saturday, January 19, the centenary of the birth of John Innes, the founder of the John Innes Horticultural Institution, was celebrated at the Institution by holding a conference on "Polyploidy," a subject which has received particular attention by the staff of the Institution during recent years. Sir David Prain occupied the chair, supported by Sir Daniel Hall, the present Director, and there was a large attendance, many prominent botanists and horticulturists being present. Prior to the commencement of the conference, Mr. Ernest Innes, a nephew of the founder, gave a brief outline of the life and work of John Innes, and of the events which resulted in the foundation of the Institution. As an introduction to the conference, Mr. J. B. S. Haldane described the meaning of the subject to be discussed, *i.e.*, polyploidy, and he was followed by Dr. C. C. Hurst, whose subject was "Polyploidy in the Genus Rosa," although he did not confine his remarks to Roses. His lecture, limited to fifteen minutes, was followed by an interesting discussion, resulting from Professor E. W. MacBride, an eminent zoologist, challenging the remark made by Dr. Hurst to the effect that he considered polyploidy had played a large part in evolution. Professor R. R. Gates next gave an account of "The Origin of Polyploids," while other aspects of the subject were dealt with in turn by Mr. J. B. S. Haldane, who spoke on "Laws of Inheritance in Polyploids" ; Dr. C. D. Darlington, whose subject was "The Importance of Chromosome Behaviour in Polyploids" ; Dr. C. L. Huskins, who gave an interesting account of "Polyploidy in Cereals" ; Dr. F. W. Sansome, who spoke on "Polyploidy in Tomatos" ; and Mr. M. B. Crane, whose subject was "Polyploidy in Strawberries, Rubus and Prunus." Keen interest was displayed by all present throughout the Conference, and after tea, kindly provided, Miss Caroline Pellew gave a demonstration in the laboratory of the progress of investigations concerning the allo-polyploid Primula kewensis, and species hybrids. A report of the Conference will appear in our next issue.

British Mycological Society.—A London meeting of this Society will be held at University College, Gower Street, W.C.1, on Saturday, January 26, 1929, at 11 a.m. The speakers and subjects are as follow :—Miss D. M. Cayley, "Some Observations on Mycetozoa of the Genus Didymium" ; Mr. A. Chaston Chapman, F.R.S., "A New Species of Oidium" ; Miss E. H. M. Farries, B.Sc., "An Investigation on the Metabolism of Nematospora Gossypii, Ashby and Nowell" ; Mr. M. Mitra, "Phytophthora parasitica, Dast., as a Parasite on Cotton Seedlings and Guava Fruits" ; Dr. Alex. Smith, "Observations on Puccinia Menthae, Pers." The authors' names are arranged alphabetically ; the papers will be given in the order most generally convenient. Lunch will be arranged in the College Refectory.

Bracken Disease in Scotland.—Widespread evidence of a fungus disease in Bracken in Scotland, together with the research work that is being done in the direction of encouraging the natural enemy of the pest, is contained in a pamphlet published by the West of Scotland Agricultural College, Glasgow. It is the work of Mrs. N. L. Alcock, the plant pathologist of the Board of Agriculture, and Professor K. W. Braid, of the Botany Department of the West of Scotland Agricultural College, and covers the period of ten years that have elapsed since the discovery of a definite disease affecting Bracken on a farm near Maybole, Ayrshire, was given publicity by Mr. John McGill, of Ayr. One of the main points revealed in the report is that the year 1928 has disclosed a widespread disease which appears virulent, can spread rapidly, and apparently is perfectly innocuous to tree life. From the reports received from research workers during the past summer, the distribution of the disease appears to be spread over the whole of Scotland south of a line through Loch Rannock. The possibilities are accordingly of real moment to Scottish Agriculture. Bracken encroaches rapidly upon valuable grazing lands, smothering grasses and other herbage. In young plantations it is equally destructive, for it shades the young trees in summer and smothers them in carpets of dead fronds in autumn and winter. The problem of extermination, short of encouraging a war on the part of nature herself, is a costly one. By the process of cutting it takes from three to seven years to eradicate the pest, and the cost, varying from 10s. to 30s. per acre, is prohibitive in most cases, as the land affected is usually of a small annual value. Bracken, it is explained, is a pest of almost world-wide prevalence.

Parasitic fungi on the stem are negligible, possibly because, except in early youth, the Bracken is too hard and dry. In the case of the disease found near Maybole, a curious dying-back of Bracken occurred over a fairly wide area. In this instance, the fungus was not isolated, but there seems good reason to believe the cause was the same as in other areas since observed. There the first phase of disease is past; all the juicy, lush Bracken has succumbed and only small, hard fronds exist. The second phase of the attack is a siege, with repeated rallies directed against the young and tender fronds. Already the grass is responding markedly. Reference is also made to outbreaks of the disease at Langholm, Garelochhead and Arran. At the latter place the Bracken was breast high three years ago and it is now dwindling gradually. In the cases specified the destruction of the current year's plant has been followed by the stimulation and growth of a smaller frond, apparently next year's. In many instances this has succumbed to the disease also and a very small frond measuring two to three inches only has appeared. So far as could be ascertained, this was the frond of 1920. The latest stages are reported from Bridge of Urr, Dalbeattie, where the areas infected a few years ago are now practically destitute of Bracken. In places, now herbage covered, abundant remains of the old underground stems can be dug up. Whether in each case it is the same fungus, or whether a normally saprophytic fungus has become an active parasite, cannot be stated with certainty. There appears to be different degrees of virulence. This may mean that there are different strains of a fungus, or that certain Bracken plants are more susceptible than others, or, again, that some external factors are influencing the natural immunity of the Bracken. In their conclusions, the authors state that it has still to be definitely proved what the fungus is and exactly what it does. It is not certain that the disease will appear another year with the same intensity, and while no promise of immediate extermination of the Bracken is made, the attack, even already, looks more hopeful. No hope of exterminating all Bracken from every area is entertained, but if disease kills some of the Bracken, man must step in and destroy the remainder.

Rainfall at Tirley Garth Gardens, Tarporley, 1928.—The rainfall in these gardens during 1928 amounted to 32·35 inches, or 4·16 inches below the total fall in 1927. The heaviest rainfall in the twenty-four hours occurred on June 7, when ·97-of-an-inch was registered. May and September were the driest months, with only 1·48 inch each. In June, the rainfall amounted to 5·15 inches, this being the wettest month of the year, with twenty-four rainy days. There were 228 days in which ·01-of-an-inch or more was registered, and 170 days in which ·04 or more was recorded. The driest period was from July 7 to July 20, when there were thirteen clear, dry days. The hottest day was on July 15, when the temperature rose to 84° in the shade. The coldest day was on December 14, when 13° of frost were registered. There were 138 days on which no rain fell. On the whole, 1928 was a good year at Tirley Garth, with abundance of healthy crops. Fruits of all kinds were plentiful.

Queen Marie of Roumania and Her Gardens.—The January number of the Roumanian gardening journal, *Revista Horticolă*, has an interesting portrait frontispiece representing Queen Marie of Roumania in her beautiful garden at Balcic. Beneath the portrait is a facsimile signature of the Queen, and her message to Roumanian horticulturists, in Roumanian and French: "Between those who grow flowers there is a harmonious bond of fraternity." It is well-known that Queen Marie has a passionate love for gardens, and takes an active interest in the planning and upkeep of her own gardens in various parts of the kingdom. Each of the gardens has its own characteristic; for instance, at Bran, Dahlias are chiefly grown; at Balcic, which is on a rocky eminence above the sea, there is almost unlimited scope for landscape effects, and of this fact full advantage has been taken with very beautiful results. Queen Marie takes a very profound interest in the affairs of the Roumanian Horticultural Society, and in Roumanian horticulture generally. She is keen on inducing growers to produce a greater variety of flowers, instead of concentrating, as the tendency is at present, on a few lines such as Chrysanthemums and Cyclamens, both of which do remarkably well in the climate prevailing in that part of Europe.

Increase in Forestry Grants.—We understand that the Government has undertaken to ask Parliament to vote a total sum of £5,500,000 to the Forestry Commission on agreed annual instalments during the ten years commencing on April 1 of this year. The sum provided during the last ten years was £3,500,000. The Commission, it is estimated, will also derive an increased revenue from all forest products to a total of about £1,400,000, as compared with £775,000, the estimated figure for the first ten years. It is expected that this increase in income will enable the Commission to lay down 225,000 acres of new plantations, to devote £1,000,000 to forest workers' holdings, and to make grants for other forestry purposes, including the planting of municipal and private land with timber trees, and forestry education and research.

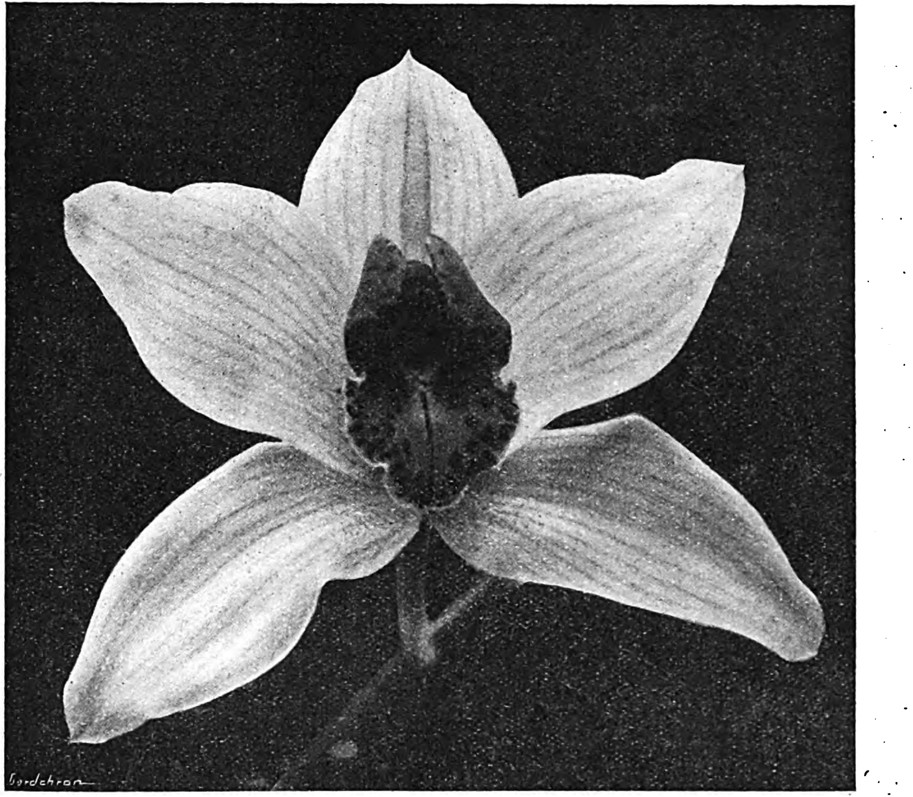

FIG. 29.—CYMBIDIUM ALBANIA.

R.H.S. First Class Certificate, January 15. Flowers pink, rose-pink and red. Shown by Mrs. Carl Holmes (gr. Mr. W. J. Penton), The Node, Welwyn, Herts.

(Described on p. 53, and stated, in error, to have been shown by Messrs. J. and A. McBean).

Appointments for the Ensuing Week.—Monday, January 28: East Anglian Institute of Agriculture's lecture; Birmingham and Midland Gardeners' Association's lecture. Tuesday, January 29: Royal Horticultural Society's Committees meet; Horticultural Club's dinner and lecture; Royal West Renfrewshire Horticultural Society meets. Wednesday, January 30: Kingston and Surbiton Chrysanthemum Society meets. Thursday, January 31: Brighton, Hove and Sussex Horticultural Society's Annual Meeting; London and South of England Viola and Pansy Society meets; British Florists' Federation's Annual Meeting and dinner. Friday, February 1: Manchester and North of England Orchid Society's exhibition; Dundee Horticultural Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Spring Flowers in the North of China.*—In the north of China, there are a number of plants which have their flower-buds very prominently developed in autumn, so much so that they are ready to burst into bloom before the winter has quite passed by, or, at all events, on the first dawn of spring. Amongst these Jasminum nudiflorum occupies a prominent position. Its yellow blossoms, which it produces in great abundance, may be seen not infrequently peeping out from amongst the snow, and reminds the stranger in these remote regions of the beautiful Primroses and Cowslips which grow on the shaded banks of his own land. Nearly as early as this, the pretty, Daisy-like Spiraea prunifolia, the yellow Forsythia viridissima, the lilac Daphne Fortunei, and the pink Judas Tree, become covered with blossoms, and make our northern Chinese gardens extremely gay. There are also some good Camellias which flower at this time, but they are generally grown in pots under such shelter as mat sheds and other buildings of a like kind can afford. The double-blossomed Peach, of which there are three very distinct varieties now in England, are, perhaps, the gayest of all things which flower in early spring. Fancy, if you can, trees fully as large as our Almond, literally loaded with rich coloured blossoms, nearly as large and double as Roses, and you will have some idea of the effect produced by these fine trees in this part of the world. On the south-west side of Shanghai there are numerous Peach gardens studded over the country. These are well worth a visit in the month of April, as the trees are then in full bloom, and have a charming effect upon the landscape. It is in this part of the country where the celebrated Shanghai Peach is largely cultivated. *Robert Fortune, Gard. Chron., January* 28, 1854.

Publications Received.—Report and Summary of the Results of Experiments at The Agricultural Institute, Kirton, during 1927.—*Le Rosier Historique: Culture en plein air et sous verre*, by Edm. van Cauwenberghe.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Semi-deciduous Dendrobiums.—The earliest plants of this group, which are resting in a cool house, should now be showing flower buds, and to extend the flowering season a batch of the earliest and most vigorous plants should be given slightly warmer conditions. Gradually increase the amount of moisture supplied at the roots and in the atmosphere in order to assist the better development of the flowers. Saturation at the roots or in the atmosphere, also a too sudden increase in the temperature, should be avoided, as this often results in the buds turning yellow and falling off. Other batches may be brought on as required; the plants will respond more quickly as the season advances. It is not advisable to allow weak plants to flower, therefore the flower buds should be removed as they appear.

Weather Effects.—The cold and extremely dull weather experienced in most parts of the country during the first half of January, made Orchid-growing rather difficult, as a good deal of fire-heat was necessary to maintain the minimum temperatures required in all divisions, and this consequently necessitated more damping down than is really good for many of the plants, especially in smoky districts where the light has been very poor indeed. The effect of these conditions on the plants is easily noticed, especially on those that have been growing throughout the winter; many cool house Odontoglossums, for instance, the growths of which are soon weakened. These subjects will now require all the light available, together with judicious ventilation and watering to assist them to build up satisfactory bulbs. The importance of securing well-ripened pseudo-bulbs in the autumn is well demonstrated now by the condition of the Cattleyas, Dendrobiums, Coelogynes, Brassias and other pseudo-bulb-producing Orchids. Fully matured and well-ripened bulbs pass through these trying conditions very well, while the partially-made winter growths will require close attention to prevent any damping-off. Fog and sunless days have a marked effect on many flowers. The most satisfactory results are to be seen at this season in the Cypripedium house, where the winter-flowering sorts continue to make a very fine display, in spite of the dismal conditions outside.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Grape Vines.—These should now be in various stages of growth, from bursting their buds to elongating their bunches. If confined to well-drained borders, a second watering with tepid water or weak liquid manure may be needed by old vines to assist the development of the bunches, and should prove sufficient until the Grapes are set. Syringing may be discontinued when all the buds have started, but the walls, paths and borders should be moistened two or three times a day, according to the weather conditions prevailing. As growth proceeds, disbudding and tying in will require daily attention, and each shoot should be pinched at the second or third joint beyond the bunch. When tying down the shoots for the first time, sufficient pressure only should be applied to keep the growths clear of the glass. Remove all but one bunch on each shoot, even on the Muscat vines, for even with this treatment enough and to spare will be left for the crop. When the vines are in free growth, temperatures varying from 55° to 60°, or a little higher, during mild weather at night, and 70° to 75°, rising to 80° after the houses have been closed, during the day, should prove suitable. The vines in the first Muscat house must be kept well syringed, while the temperature, maintained by a gentle circulation of heat, should be between 60° and 65°, according to outside conditions, and during fog or frost, 10° lower at night. The young vines may be bent over to ensure even starting of growth. If grafting or inarching on to any of the old vines is contemplated, the scions, or young vines in pots, should now be placed in gentle heat to set the sap in motion. Bottle grafting may be employed when the vines are in a dormant state, but a little excitement of growth facilitates the union, which may be made at any convenient place near the base of the stock, or upon a strong side-shoot that does not start from a spur. Possibly the best time to attach bottle-grafts is when the vine is in full leaf, after the first flush of sap is over. When the scions have started growing, pinch the shoots of the stock vine back closely, and gradually cut it down as the young canes progress and are able to take up the extra sap thus diverted. Old useless vines may be cut down and used as scions upon which to inarch the green wood of pot vines when the latter have started into growth.

Late Vineries.—If all the vines in the late houses have been pruned, the houses cleaned and the borders top-dressed, they may be kept fairly dry and cool until the first week in March, the outside borders being protected with fresh stable litter or Bracken. Two months' rest is of paramount importance to these; all the ventilators should be kept open, and no plants should be introduced that will not withstand this treatment.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Wall Gardens.—In the process of garden formation, there is often the opportunity of carrying out a scheme of wall gardening. Many existing grass terraces, which require constant attention by mowing during spring and summer, might with advantage be utilised for this fascinating form of gardening. Where stone can be procured easily in the district, that material should be used rather than going to the expense of bringing stone of an entirely different character into use. If the walls are to be, say, from four to five feet in height, it is of great importance to see that a firm and substantial foundation is provided. At least two layers of stones below the surface should be allowed for such walls. When building the walls the stones should all tip a little downwards at the back, as by so doing moisture will find its way more easily to the roots of the plants. All rock walls should be slightly battered, *i.e.*, sloping backwards. This adds considerably to their strength, and there is less chance of them bulging out at any weak part after heavy rains. When building, see that the stones are laid so that they bind each other in the same manner as adopted when building a brick wall. It is equally important that the soil used, both between the stones and at the back of the wall, is of the right material. Good soil at the back of the wall is most essential, as the future welfare of the plant depends on this. If the scheme for planting has been settled before building commences, and the necessary plants are at hand, it will be found a most convenient method to plant as the wall is being built. A moderately thin layer of soil should be placed on the stones and the plants laid out with their roots spread towards the soil at the back. Much larger plants may be used when this method of planting is adopted than when they are put in after the wall is completed, nor will they suffer so much during dry weather in the first season of growth. See that the soil at the back of the wall is made firm as the work of construction proceeds, otherwise heavy rain may cause much damage. For crowning such walls various methods may be employed. Those near formal buildings are best finished with flat coping stones; small plants of Sedums, Saxifrages and Dianthus and other small alpines may be used with effect in the joints. Use may be made of the great variety of dwarf and semi-dwarf shrubs suitable for planting along the top of the wall, or a border, in proportion to the height of the wall and the surrounding ground, may be made and planted with bulbous plants, Irises, etc.

Plants for a Rock Wall.—The choice of material for filling the crevices of the walls is unlimited. Many difficult alpine plants that usually die during winter when planted on the rock garden, will survive many years in the rock wall. A number of the commoner alpines seem to be happy in any aspect and soon make a wonderful display. For the choicer sorts, the proper aspect should be chosen, so far as the wall will allow. Campanulas in such kinds as C. Raineri, C. excisa, C. garganica, and that popular plant of cottage windows, C. isophylla, all do well in a sunny position. Lithospermum prostratum and its variety Heavenly Blue, and L. graminifolium should find a place near the top of the wall where it is moderately cool. Iberis of various sorts are useful, making attractive evergreen hummocks during winter; while Helianthemums, of which there are many good, little-known varieties, should include Ben Nevis, Ben Lui, St. John's College Yellow, Wisley Primrose, The Bride, rubens, Chocolate Blotch, Apricot, Watergate Pink, Ben Ledi, Jock Scott, Fire Dragon and Ben Venue. Aubrietias should be represented by Carnival, Dr. Mules, Prichards' A.1., and Magician. The alpine section of Phlox contains many choice varieties useful for this purpose. Among the best are G. F. Wilson, Vivid, Daisy Hill and nivalis. Phyteuma comosum, Acantholimon venustum, Aethionema grandiflorum and A. Warley Rose, Sedum Lydium, S. spathufolium, Veronica pimeleoides, Wahlenbergia dalmatica, Erinus alpinus, Gypsophila repens, Onosma stellulatum, O. tauricum, Hypericum repens and H. reptans, may all be used, while many of the encrusted Saxifrages should find a home in sunny walls. In the large genus of Dianthus many fine species will be found, which never look better than when clothing the face of a wall. For a northern aspect a few specimens of the beautiful Ramondia pyrenaica and Haberlea rhodopensis and H. Ferdinandi-Coburgi should not be overlooked. These, and the mossy Saxifrages, alpine Auriculas, Androsace lanuginosa, A. Laggeri, Primula marginata, P. viscosa, and Arenaria balearica (known as the Fairy's Carpet), should be given a damp, shady spot.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hatfield, Hertfordshire.

Hippeastrums.—These bulbous subjects may be had in flower over a fairly long period, by introducing them into gentle warmth at intervals of two or three weeks. If it is desired to have some in flower at an early date, a few of the most promising bulbs may be placed in a house with a moderately high temperature. Hippeastrums resent overpotting and disturbance of the roots, and probably most of the specimens will only require top-dressing with rich soil, after removing a portion of the old soil from the surface, and thoroughly soaking them in tepid water. At this season of the year it may be wise to plunge the receptacles in a moderately warm hot-bed of leaves. Very little water will be required until the leaves and roots are growing actively, but it is necessary to spray them lightly with tepid water twice daily when the outside conditions permit.

Flowering Shrubs.—Where pot plants have to be provided in quantity, there is nothing more suitable for this purpose than flowering shrubs, for if carefully selected, they may be had in a large range of colours, while they are neither difficult nor expensive to grow. Among those shrubs most suitable for pot culture are Lilacs, Wistarias, Viburnums, Azaleas (Mollis), Rhododendrons, Laburnums and Prunus triloba, to mention but a few. In the early stages of forcing them, guard against high temperatures, which only encourage the production of weakened growths and flowers of poor quality. There is nothing more suitable than a recently-started Peach house in which to grow these subjects, as the low temperatures to which the Peach trees are subjected in their early stages of growth should suit the development of all flowering shrubs.

Forced Tulips.—Early forced Tulips are sometimes disappointing by reason of their short flower stems. This may be due to various reasons, perhaps the most common faults being the growing of them in too high temperatures, insufficient roots, and too much light in their early stages of growth. Tulips should have their receptacles well filled with roots before they are introduced into moderate heat, when, for a short time, they should be stood under the stage in a partially darkened position. A light layer of moss placed over the pots should assist the plants to make top growth, but the moss should be removed as the flower buds push through it. The extra trouble so taken will be well repaid by the production of long-stemmed, well-coloured flowers, provided the plants are gradually inured to the light when the flowers are about half developed. This method is only recommended for early forcing.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

Loganberries and Brambles.—These fruits are much appreciated, as they come into season when most of the other small fruits are over. Propagation of them is generally effected by layering the tips of the current season's shoots during early September. If the points of the shoots are buried three or four inches deep, they will produce roots and growth buds immediately. These may be severed from the parent cane and planted, two feet apart every way, in nursery rows for a year. Their permanent situation should be open and sunny, but somewhat sheltered from cutting winds, as when grown in bleak situations the growths are stunted and the berries undersized. In good soil, these subjects produce growths eight to ten feet in length annually; therefore, when being planted, they should be spaced that distance apart, and five to six feet should be allowed between the rows. The growths, which are very strong and rampant, require support. There are various methods of affording this, but the best support I have tried took the form of strong posts, five feet above the ground and six feet apart, to which wire netting, having a three-inch mesh, was securely fixed. The growths were trained out fan-wise and tied to this fence. Each year young canes are produced from the base. These should be tied in regularly between the fruiting canes, the old canes, after fruiting, being removed. The Loganberry, which came to us from America, is most prolific, the fruits being especially valuable for preserving or bottling. The Veitchberry, raised by crossing November Abundance Raspberry with a Bramble, succeeds the Raspberry in season, and the fruits are much larger. Wilson Junior is quite one of the best of the American Blackberries, and may be recommended.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Mushrooms.—Where fresh horse manure can be procured, it should, upon arrival, be placed in a shed and turned occasionally, after which it should be heaped up and left for a few days. This will result in the development of heat, and in two or three days time the manure should be turned again, after which it may be utilised. The Mushroom bed should be made in layers, making each firm as the building of it proceeds, until it is from two- to two-and-a-half feet deep, which should be a suitable depth. Plunge a thermometer into the bed and leave it there for a day or two; when the temperature has fallen to 85° to 95°, insert the spawn and cover the bed with a layer of good loam that has previously been passed through a half-inch-mesh sieve. A layer of loam about two inches in depth should be sufficient, and this should be beaten quite firmly; it cannot be made too solid for Mushrooms. After the spawn has been planted, give the bed a thorough soaking with tepid water and maintain a temperature, if possible, of not less than 55° to 65°. Damp the bed every morning, and when the first Mushrooms appear, which should be about five or six weeks after spawning, cover the bed with a light layer of old hay to keep the surface of the bed moist.

Peas.—Early Peas may now be sown in nine- or ten-inch pots. Place three or four crocks in the bottom of each pot for drainage and some rough pieces of turf. Good loam and a little leaf-mould and decayed manure, well mixed together, should form a suitable compost. A sowing may also be made in the open ground on a south border, where the ground is dry, using a good early variety. Peter Pan and American Wonder are two reliable varieties. Do not sow the seeds too deeply, or they may rot, and cover them, if practicable, with old Chrysanthemum soil. Watch carefully for mice, as they are very destructive to Peas; if they prove troublesome, traps must be set, baited with pieces of roasted cheese.

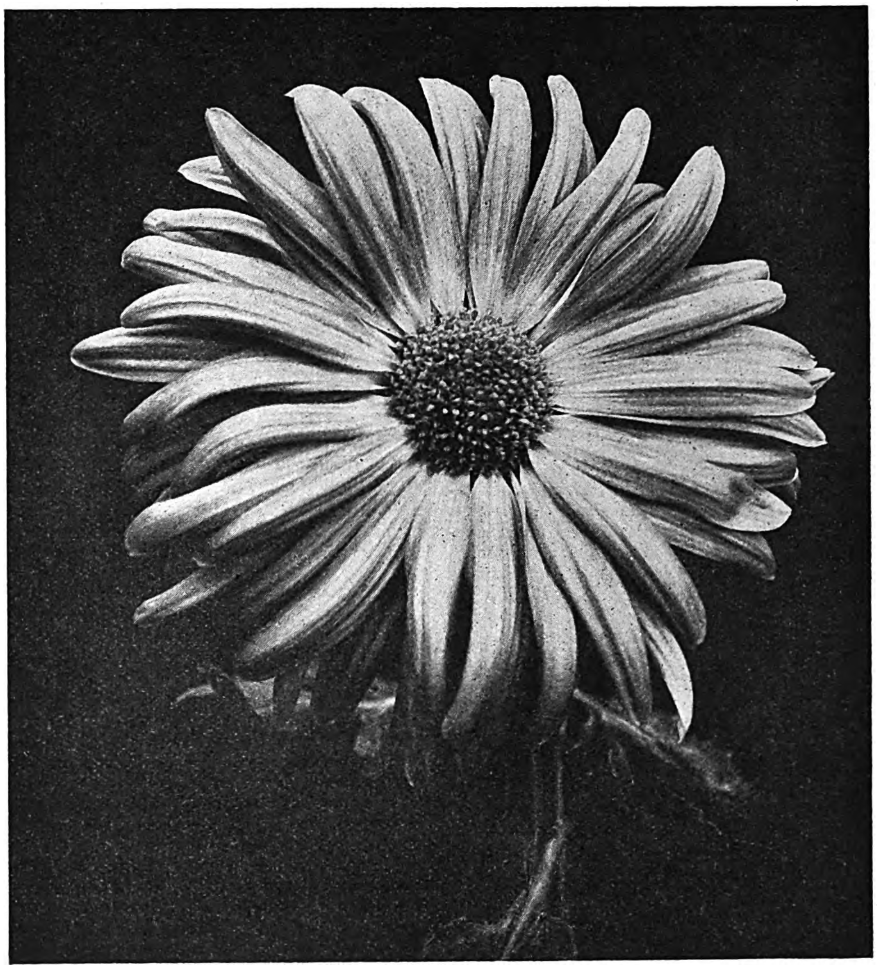

FIG. 30.—CHRYSANTHEMUM NEW YEAR.

R.H.S. Award of Merit, January 15. Flowers golden-amber. Shown by Mr. H. Shoesmith, Junr.

(see p. 53.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Early Potatos.—If heated frames are available, Potatos to produce an early supply of tubers, may be grown in pots or planted out in the frames. Pots are very handy as they may be shifted from one place to another. A good reliable variety should be grown, such as Brydon's Crompton, Victory, Duke of York or Sharpe's Express. These produce a dwarf haulm and consequently require less space than many other varieties.

Jerusalem Artichokes.—If the Jerusalem Artichoke tubers have not been lifted, this work should be done forthwith. Select the tubers required for planting this year, and place the remainder in ashes or sand, for use as required. The ground in which they have been grown should be heavily dressed with manure and dug previous to planting another crop on it, while it will require frequent hoeing during the summer, as it is practically impossible to clear all the Artichoke tubers out of the soil and they are liable to prove troublesome when they commence growth.

Asparagus.—Asparagus beds that have not been so treated should be mulched with manure at once. If manure is not available, two-year-old leaf-mould, applied now, should be suitable for protecting the crowns. In the first week of March, apply a dressing of agricultural salt. Sea-weed is probably the best dressing material for Asparagus, but it is not easy to procure.

Cauliflowers.—Cauliflower plants that are being wintered in frames should be afforded plenty of air on bright days. Any decayed leaves should be removed, while the surface of the soil should be stirred frequently. Slugs often prove troublesome to Cauliflowers under these conditions, but occasional dustings of soot should effectively check their activities.

Runner Beans.—If Runner Beans are to be grown, trenches should be taken out two feet wide and the same in depth, and plenty of leaves and any rough material placed in the bottom. This should be covered with a good dressing of cow manure or well-decayed horse manure, after which the soil may be replaced, leaving the surface as rough as possible. It is advisable to place a stake at each end of the trench, in the centre, as a guide to its position when the time for planting arrives.

FLOWER GARDEN.

EARLY-FLOWERING CHRYSANTHEMUMS.

At a season of the year when lovers of the ever popular early-flowering Chrysanthemum are placing their orders with nurserymen, perhaps a slight review of the leading varieties will not be out of place. In large private establishments where the stately Japanese and graceful Singles are a feature as pot plants, the early-flowering varieties seem to be neglected, usually because employers tire of seeing Chrysanthemums from September until Christmas.

But in limited establishments and among the small exhibitors, they always occupy the best place in the garden.

White varieties are always in demand, the best for disbudding purposes being Kathleen Wells, Framfield White, Débutante and September White; the latter is a great favourite in this district. Mayford White and Lichfield White are best when grown in natural sprays.

There seems to be a shortage of really good yellow sorts for disbudding. September Yellow occupies pride of place for size, being a canary-coloured sport from September White, while the newer Madeline promises well. Gold Dame and Golden Ritchie are well worthy of inclusion in a collection. Goldfinder is best in sprays, as disbudding does not increase the size of the blooms to any great extent.

Of the pale pink sorts, Pink Delight and Uxbridge Pink are the best, with Normandie and Jessie McAlpine, equally good as spray varieties. Deep pink varieties are numerous, Silver Queen being easily the best—in my opinion, it is the finest early Chrysanthemum ever introduced; Shirley Pride, Shirley Rose and Berengaria are all good when disbudded. There is still a need for a good red variety. Of those in cultivation, Crimson Circle, Brightness and Mrs. Wm. Sydenham are the three best, with Red Almirante, a beautiful variety for spray purposes.

Chestnut shades are numerous, with Hotspur the favourite; this grand variety should be grown by everyone. Armorel is good and Almirante is a useful spray sort. September Glory is a magnificent variety for disbudding, being a rich amber-bronze in colour, while Harvester is a good bronze-flowered sort for spray purposes. Dick Barnes, of a purple-maroon or burgundy shade, responds well to disbudding, while Minstrel is an attractive maroon-coloured sort for spray work.

Were I requested to select a dozen early-flowering Chrysanthemums for disbudding, my choice would be September White and Kathleen Wells, white; September Yellow and Gold Dame, yellow; Silver Queen, deep pink; Pink Delight, pale pink; Crimson Circle and Hotspur, chestnut; September Glory, bronze; Dick Barnes, maroon; Cranford Cream, and Salmon Queen, the last named being of a peculiar shade of salmon-bronze.

To obtain good disbudded flowers in September, varieties catalogued as September-flowering usually do best if allowed to break naturally and produce from four to six flowers per plant. October-flowering varieties may be had in bloom earlier if stopped once early in May and three or four blooms are allowed to develop on each plant. *A. J. Turner.*

CYNOGLOSSUM AMABILE.

Several years have elapsed since this beautiful Hound's-tongue was introduced to cultivation in this country, yet it does not seem to have found favour in gardens, probably, in the first place, because it is biennial, although it sometimes lasts for a third year, and secondly, because it may hardly be regarded as hardy. In the warmer parts of the country the young plants probably pass through the winter safely, but in the colder parts, or so has been my experience, a large proportion of them are destroyed, so much so that I have adopted the practice of sowing the seeds in early autumn—one plant alone will produce enough for ordinary garden purposes, and they retain their vitality for at least two years—and planting the seedlings out when of good size the following spring, to produce a display in the latter half of summer. It is surprising that self-sown seedlings seem to survive the winter much better than those raised specially, and these often appear in the most unlikely places and develop into large, floriferous specimens.

The method I practice is to sow the seeds during early autumn, in five-inch pots or shallow boxes of open soil, in a warm house. So soon as the seedlings show the first rough leaves, they are pricked out into large sixty-sized pots, in which they are well established prior to being hardened off and wintered in a cold frame. They are planted out at the end of April or early in May, fairly closely together, in beds of well-prepared soil, in which they establish themselves quickly.

Cynoglossum amabile has rather narrow, ovate leaves, silvery-green and downy, tapering to slender stems. From among these rises the branched flower-stem, from two feet to, in some cases, three feet high, bearing numerous intense pale-blue, Forget-me-not-like flowers, very bright and, when seen in groups, very charming and effective.

There is a white form, also a pink, both of which appear sometimes among seedlings from the type, which seems to suggest that these colour variations are natural to it in the wild state, but they are not so attractive nor so effective as the blue-flowered type for garden adornment. *Kent.*

TREES AND SHRUBS.

SALIX LANATA.

A native of high altitudes over a wide part of Europe and Asia, including northern Scotland, this little Willow makes a stout-branched, sturdy shrub usually under three feet in height. It is a deciduous species, and the oval or obovate leaves, which are over two inches long and about half as wide, are so covered by a coating of dense grey hairs that the foliage has a silvery appearance, especially in spring. The bright yellow catkins, which are about two inches long and half-an-inch across, are decidedly attractive in conjunction with the woolly foliage, both being at their best in May.

S. lanata is a useful little bush for associating with other dwarf subjects near a small pool or stream, and one that will always strike a distinctive note so long as it is not overgrown by taller subjects. A few years ago, some cuttings of S. lanata var. Stewartii were given to me, these coming from the original stock which was, I believe, held by some of the members of Farrer's old nursery company. The cuttings rooted successfully in the open ground, but I have not yet been able to determine what the difference is between this variety and the type. Curiously enough, since I inserted the above and left them to their own devices, raising every one, I have been told that this variety is very difficult to strike! *J.*

PARROTIA PERSICA.

Of all the shrubs which provide a spectacular display in the autumn months, few can equal Parrotia, either in brilliance or the duration of its scarlet and gold colouring. There are shrubs whose leaves may change to pure yellow, and others entirely red, but examples of the two colours effectively combined are uncommon—some of the Pyrus, perhaps, and Cercidiphyllum japonicum, come to mind.

In cultivation, P. persica forms a large shrub of perhaps twenty feet in height; the branches spread upwards and outwards from the base, and owing to this habit it is possibly best grown as an isolated specimen, with a dark background of trees to display the autumn colouring. The bark is smooth, and the wood extremely hard and durable. Like other genus of the Hamamelidaceae, to which Order it belongs, the flowers appear on the bare twigs, usually in February. The buds are covered by brown, woolly scales, which open to disclose a bunch of red stamens, hanging on slender filaments; these form the most decorative parts of the flowers. The leaves are from three to four inches long, nearly oval, while the upper half is toothed or waved; the bright colours are assumed during the latter half of September and, given dry weather, the leaves will remain a glowing picture for nearly a month.

This shrub is, of course, a native of Persia, as the specific name denotes; the generic name was given in honour of a German traveller and botanist, named Professor Parrot.

In the *Bot. Mag.*, t. 5,744 (1868) it is described as one of the rarest trees in cultivation at that time, although it had been introduced nearly thirty years previously. Propagation may be carried out by means of layers. *B. O. M.*

ALPINE GARDEN.

THE HOUSTONIAS.

Universally admitted to be among the choicest of our rock plants are the Houstonias, called in their native land, America, Bluets or Innocence. The number known to botanists is considerably greater than that of those in commerce, and a short note on the latter will be of more value than a lengthened dissertation upon the genus as a whole.

These plants are all very dwarf, rarely exceeding three or four inches, and are of inestimable charm. They form close-growing carpets of small, charming, green leaves, smothered, usually from May onwards, by hosts of small, four-petalled, blue, purple or white flowers. This floriferousness is frequently too severe a strain upon the constitution of the plant, which, in many places, succumbs after flowering. Yet, if some consideration is given to the requirements of these Houstonias, they may live for many years. With me, they appear to require a certain amount of shade, but this should not be too deep. They like a very light and sandy soil, but, on the other hand, this should not be too dry during the growing and flowering season.

The late Mr. Reginald Farrer advised water beneath, but in many gardens this cannot be supplied. The alternative is frequent waterings with clear water during dry weather. This the writer has practised with great advantage. Another point which has been beneficial has been the occasional removal of all the flowers, an unwelcome task, but the future welfare of the plant justifies such sacrifice.

The Houstonias in commerce, as already stated, are not numerous. The favourite among them is Houstonia coerulea, about three inches high, with lovely little pale blue flowers. It is a real gem among alpine flowers. The white variety, alba, is not at all common in gardens, and is highly prized by most folks, although I consider the typical blue form the more delightful. H. serpyllifolia is rather larger in its parts and more spreading in habit, with the flowers deeply tinted with violet. It is alleged to be the hardiest of the race, but with similar care H. coerulea is quite as hardy. So far as I know, these are the only Houstonias at present in commerce in this country.

Planting may be effected in spring. Farrer stated the finest plants he ever saw were in a wet and heavy, calcareous loam; but calcareous soils are not necessary, and a lighter soil is, I feel confident, better for the Houstonias than a heavy one. *S. Arnott.*

BELLIUM MINUTUM.

This charming, minute little Daisy—the Little Mary—is never so happy as when growing in the crevices of stone paths and steps, for despite its lowly stature of about one inch, it spreads freely, forming mats of closely packed, tiny leaves, and covering them, from May onwards until early July, with miniature, white, Daisy flowers, flushed with purplish-pink on the reverse side.

The whole plant is unassuming in nature, but it is nevertheless an attractive little subject, and useful for furnishing such positions as stated above. It is a native of Greece, absolutely hardy, and easy to establish, asking for no especial soil conditions and not objecting to partial shade, although it seems to prefer full sun. *M. W.*

INDOOR PLANTS.

CINERARIAS.

Few annuals grown for the embellishment of the conservatory or cool greenhouse, as well as for decorative purposes, are more attractive and useful than Cinerarias, while the improvements effected by the hybridists in the size and colour of the flowers, together with the comparative ease of their cultivation, will always insure a high position for this popular plant in public favour.

At no period of growth does the Cineraria require a higher temperature than that of an ordinary greenhouse, but its cultivation, although simple, must be thorough if the best results are to be obtained—due regard being given to potting on so soon as necessary, a careful use of the watering-can at all stages of growth, and free ventilation on all occasions when the weather conditions are favourable.

Propagation of the florists' varieties is generally effected by seeds, and most leading houses of seedsmen offer particularly fine strains of both the large-flowered and the stellata forms—the two most commonly grown—at comparatively low prices, and in a variety of colours ranging from white, blue, violet, lilac and pink, to red and crimson. The stellata type produces large, spreading panicles of starry flowers on long stalks, and has the additional advantage, when cut and placed in water with foliage, of lasting a considerable time. There are also double and Cactus-flowered strains, but these are not so well known.

The time of sowing the seeds depends on when it is desired to have the plants in flower. They are usually required for the earliest months of the year, therefore seeds should be sown in May, and again in June to provide a succession—plants from the latter sowing should produce flowers the following March or April. It is quite possible to have Cinerarias in bloom in November and December by sowing in April. Shallow pans will be found suitable receptacles for seed-sowing, and these should have ample drainage and be filled to within one inch of the top with well prepared soil. After watering the soil well with a fine-rosed can, scatter the seeds thinly over the surface, and cover them lightly with fine soil, afterwards placing them in a temperature of 55°. A piece of glass and a sheet of paper placed over the receptacle is beneficial until germination takes place, when the seedlings should be exposed to full light, only shading them from very hot sunshine; admit air freely, but avoid creating cold draughts.

A suitable compost in which to sow the seeds consists of one part good mellow loam to two parts of leaf-mould, with sufficient silver-sand added to keep the whole open. After mixing it well, pass it through a quarter-of-an-inch-mesh sieve. A similar soil, but coarser in character, may also be used for the plants in their seedling stage, with an increase of the loam content. For the final potting, the compost should be one of equal parts fibrous loam and leaf-mould, with silver-sand and a little well decayed manure added. It is not advisable to make up a too rich compost for Cinerarias; rather depend on feeding when the plants have well filled their flowering pots with roots, as planting them in a rich compost encourages weak growth and an over production of foliage.

So soon as the seedlings are large enough to handle they should be pricked off, either into small pots, or—and this is preferable—two to three inches apart in boxes, placing them in a close frame where they may be shaded when necessary, and sprinkling them with soft water each morning and evening when outside conditions permit. When it is seen they are commencing to grow, air should be admitted whenever practicable, for at no stage of their growth should Cinerarias be coddled. As the plants fill the intervening spaces they should be potted; the largest will require pots four inches in diameter, while sixty-sized pots will be found sufficient for the weaklings—these may not require pots above five inches in diameter even for the final shift, but are often found very useful for decorative purposes where a receptacle of larger dimensions is unsuitable. After this potting, return them to the frame, which should be kept close for a few days until the roots have commenced to take possession of the fresh compost, after which admit air freely, even leaving the lights off altogether on fine nights, as the late summer and autumn dews are most beneficial to healthy growth. It is also necessary to shade them from very bright sunshine; for this reason a frame under a north wall is most suitable for them. As Cinerarias are quick-growing and free-rooting subjects, care should be exercised to prevent them becoming pot-bound until in the flowering pots, which should be six or seven inches in diameter, although if it is desired to have large specimens, eight or nine-inch pots would not be too large, but an intermediate move is advised before placing them in these.

After the final potting, return the specimens to the frame, allowing ample room for development between the plants, which should be placed on inverted flower pots on a bed of sifted ashes. Endeavour to have them in their flowering pots so soon as possible, to allow of their being well established before the shorter days arrive. Subsequent treatment consists of a gentle spraying overhead whenever climatic conditions allow; a judicious use of the watering-can, and rigorous attention to airing and shading. On the approach of winter and the advent of sharp frosts, the plants should be "housed"—a heated pit, or light, airy greenhouse, with a maximum temperature of 50°, should prove suitable. Endeavour to maintain a fairly moist atmosphere, admitting an abundance of air on all suitable occasions.

With the first appearance of the flower buds, feeding should commence; weak liquid manure, soot-water and an occasional top-dressing of an approved fertiliser may advantageously be applied, while a suitable "complete" manure consists of ¼-lb. muriate of potash, ½-lb. superphosphate and ¾-lb. nitrate of soda, dissolved in twenty-five gallons of water, and given every ten days. Feeding should cease so soon as the flowers show colour.

There are a host of enemies that attack Cinerarias, but the two most troublesome are aphis and the leaf-mining grub. Free, healthy growth is the best antidote for the former, but should it make its appearance, prompt fumigation with XL All, or a similar fumigant, should eradicate it. The leaf-miner is more difficult to deal with, but fumigation with auto-shreds should prove effective, while it may also be destroyed by pressing the infested leaf between the thumb and finger. *T. Wilson, Moreton Paddox.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

WILLIAM BATESON.

AMONG the chief distinctions in the world of horticulture is the Victoria Medal of Honour, conferred by the Royal Horticultural Society. Although the list of living recipients is so high as sixty-three — the number of years that Queen Victoria reigned —the names of professional scientific men, whether botanists, physiologists or chemists, are not often to be found in it. It was an honour conferred upon William Bateson, and it was an honour which he wore with pride. Yet Bateson was by upbringing and training a zoologist, and in the earlier part of his career his researches were mainly concerned with animals. How then did it come about that his name, as that of one who had rendered distinguished service to horticulture, should have been preferred above those of many eminent botanists by profession? To answer that question rightly would be to state what Bateson stood for in the horticultural world, and to attempt it is to go back some way in the development of scientific thought.

As everybody knows, Linnaeus is the dominating figure in the botanical history of the eighteenth century. It was the century of classification and order, and the great *Systema Naturae* marks its climax. At the root of it all lay the idea of the immutability of species; that living creatures were as they had issued from the mint of the Creator, save, perhaps, for a little tarnish engendered by forced contact with a sinful world. That species would occasionally cross was known, but the common sterility of such products was against their introducing any disorder into the creative scheme. Even when the hybrids might, as in rare cases, prove fertile, the work of Kölreuter seemed to show that they eventually reverted to a parental form.

Horticulture, as understood to-day, was still in its infancy, and relatively little was being effected by gardeners in improving the strains which had been handed on to them. Although some flowers, such as Pinks and Tulips, existed in considerable diversity, there was nothing really comparable to the rapid evolution of the Delphinium, the Sweet Pea, or the Primula in recent times, to arrest a man's attention and to set him thinking how it might have come about. The natural philosophers, too, when they paid attention to these matters were chiefly interested in lauding the beneficence of the Creator as manifested in the beauty of his handiwork, and in its perfect adaptation to its purpose. Indeed, they did little more than ring the changes on the later chapters of the Book of Job. Nothing in the thought of the time was opposed to the conception of the fixity of species until Buffon cautiously hinted at transmutation. With Erasmus Darwin and Lamarck came the idea of gradual evolution, ultimately stated in an acceptable form in Charles Darwin's *Origin of Species*.

Darwin's theory of Natural Selection was, of course, based largely upon the facts which he had so diligently collected from the breeders. By that time the breeding of animals and plants had made considerable progress. New and improved races had been produced from the older material and fixed by selection on the part of the breeder, and their procedure Darwin considered analogous to that taking place under natural conditions. Natural Selection here took the place of the artificial selection practised by the breeder.

In this way, the world was led to a conception of the nature of species entirely different to that which had hitherto prevailed. Living things were all subject to variations which were transmissible through some mysterious process of heredity. By concentrating upon a slight variation and selecting it for some generations, it could be gradually increased and worked up into a tangible fresh character; on the cessation of selection it would tend to revert to the original condition. In other words, the living thing was plastic, and by the selective process could be moulded into this form or into that. A species was no longer a fixed thing for, although ever so slightly, it was something different yesterday and would be something different again to-morrow.

By botanists and zoologists the idea of evolution was eagerly accepted, and they at once set to work to discover how far the facts of plant and animal structure fell into line with the evolutionary idea—in what way the various groups of living things could be related to one another on evolutionary principles. Comparative morphology and embryology became the order of the day, and in every laboratory the clicking of the microtome heralded some fresh view on the ancestry of this or that group. Intense as was the activity of the laboratory, it was remote from the study of the living thing, whose very existence seemed to be for little else than to serve as material for pickling and dissection. So there formed a deep gulf between the professional biologist and the growers of plants and animals, for neither understood nor sympathised with the problems of the other.

It was here that Bateson came upon the scene. Although himself, in earlier days, a brilliant exponent of the methods current in the laboratory, he quickly came to mistrust the utility of such work. After all, the great problem before the naturalist was the understanding of the nature of species, what they are, and how they have come about. Of what use was it to elaborate hypotheses as to how one great group of the animal or plant kingdoms might be related to another when we could conceive no satisfying idea as to the way in which a given species might pass into a closely related one?

Bateson suggested that the best way of attacking the problem was to note carefully what sort of variations actually did occur in living things, but his scientific brethren paid little heed to him. So he started off by himself to collect all such facts as seemed to him to bear upon the matter, digging into the literature, searching museums at home and abroad, and above all things turning again, like Darwin before him, to the breeders of animals and plants. As the outcome appeared his great work *Materials for the Study of Variation*, wherein he definitely stated what is known as the principle of Discontinuity in Variation. A given variety may exist beside another without the existence of intermediate forms. Such, for example, is the dwarf Cupid Sweet Pea as compared with

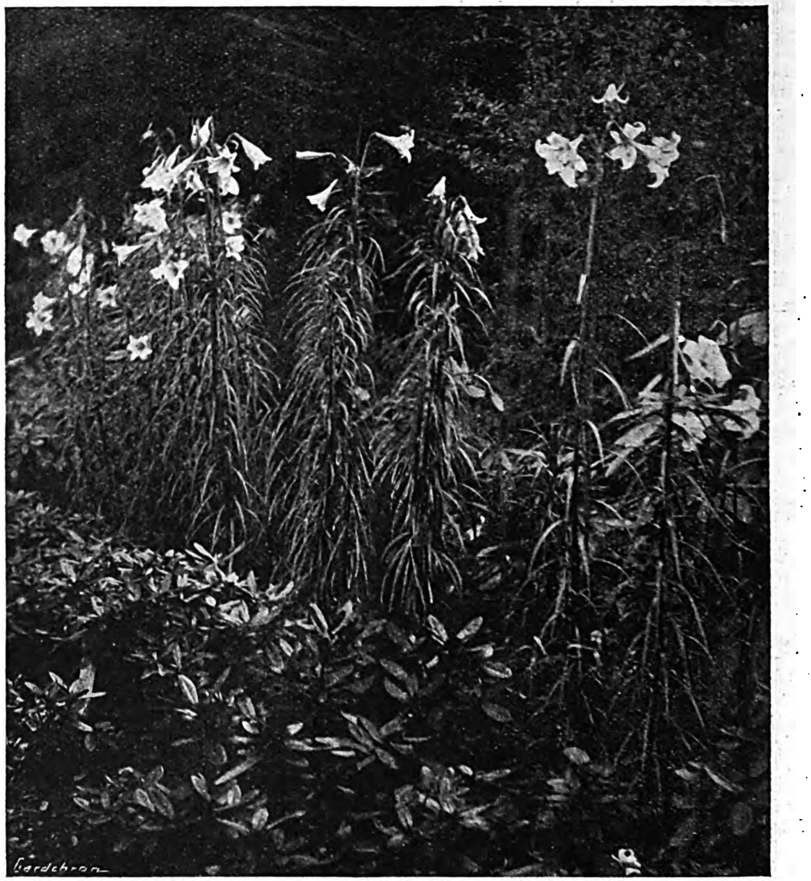

FIG. 32.—LILIUM PHILIPPINENSE VAR. FORMOSANUM AT CASTLE KENNEDY.

the normal form. There are no intermediates known, yet nothing is more certain than that the dwarf was derived from the tall in spite of the absence of intermediates bridging over the discontinuity in height. *Natura non facit saltum* proclaimed the orthodox, whereas Bateson held that the reverse must often be the case. His views, naturally enough, led him into controversies, of which one of the earliest resulted in his demonstration that the varied forms of cultivated Cinerarias owed their origin to hybridisation rather than to gradual evolution through constant selection from a wild form.

It was work such as this that brought him into that close contact with the growers that lasted throughout his life and turned his thoughts in the direction of experimental crossing. For he saw clearly that the next stage must be to cross discontinuous varieties together and follow out carefully what took place in succeeding generations. Experiments of this nature were already well under way when the dramatic re-discovery of Mendel's paper placed all these matters in a fresh light. Through his previous work, Bateson's mind had been so attuned that he instantly realised its great significance, and thenceforward, Mendel's principle of segregation became the guiding thread of his own experimental work, as well as of many another worker directly inspired by him. For many discoveries, such as the explanation of reversion on crossing, and of linkage of characters in heredity, the horticultural world is directly indebted to Bateson. Directly also, is it indebted for an exposition of the nature of living things as revealed by the phenomena of heredity that in its way is unsurpassed. There is a tendency in these days of chromosomes and genes to regard *Mendel's Principles of Heredity* as out of date, yet there is no general work that can be read with greater profit by the student of heredity to-day, for there is none that demonstrates so clearly the logical method of attacking a problem, or is so clearly illuminated by critical insight. And now that the Cambridge University Press has issued a collected edition of his papers, the horticultural world is in a position to estimate the value of the legacy he left it. On some aspects of Bateson's contributions we hope to touch in subsequent issues of *The Gardeners' Chronicle*. But important as these are, there is one service rendered by him which, perhaps, is even greater. For by his teaching and by his example he broke down the barrier which had grown up between men of science and men of practice, between those who make knowledge and those who use it. He made both sides realise that their special problems had much in common, that the one could help the other, and by so doing pave the way to that increased control over natural forces without which civilisation must inevitably stagnate into death.

LILIUM PHILIPPINENSE VAR. FORMOSANUM.

THIS beautiful Lily has been a success at Castle Kennedy, Wigtownshire, especially where planted among Rhododendrons (Fig. 32). It is also a good subject for massing in a shrubbery border (Fig. 33) as it blooms late in the season. Until recently it was thought that Lilium philippinense var. formosanum could not be grown out-of-doors, but I believe it to be far hardier than most people think. The photographs sent herewith were taken on November 21, 1928, after a very cold night, when we experienced 5° of frost, and I had almost despaired of securing the photographs I so much desired. However, the plants and flowers came through the ordeal successfully and were apparently undamaged. I feel sure that winds and rains do more damage than the cold. Some of the flower stems reached a height of six feet; one (Fig. 34) carried a head of eight and another one of ten flowers.

L. philippinense var. formosanum may be flowered in two years from seed-sowing, but owing to the fact that it flowers so late in the season, it is almost impossible to secure seeds from outdoor plants. However, it gives off numerous small bulblets, and these may be easily nursed along into flowering size.

This fine Lily is a native of the island of Formosa, where I believe it is the only native species. It is stated to be common from the sea-level up to 10,000 feet elevation. Wilson, in his *Lilies of Eastern Asia*, writes of finding it over six feet tall, and he also states that plants may be found in flower in nearly every month of the year at the lower altitudes. *R. W. Rye, The Gardens, Castle Kennedy.*

NOTICE OF BOOK.

American Fruit-growing.

ANY person who wishes to gain some knowledge of the methods of commercial fruit-growing followed in the United States, can do so very quickly by reading this book.* The author, who is a well-known authority on fruit-growing in America, wastes no words and gives a great deal of information in a small space. Although, in the editor's preface, the book is described as being intended for "wide-awake and ambitious fruit-growers," we judge from its simple style that the author really intended it for "the boys and girls of America, the fruit-growers of the future," to whom he dedicates the volume. In other words, it is a book for the beginner and the student, rather than for the experienced grower.

The pruning of Apples and Pears in America consists almost entirely of thinning out. No mention is made of spurring. The trees are headed down when planted, and apparently make very free growth in their early years. Once the required number of "scaffold" branches has been obtained to lay the foundation of the head, there is no further shortening of shoots, except such as is required to prevent crowding. Pruning is concerned mainly with the removal of small branches where they are too close together or crossing. Laterals are evidently allowed to form fruit spurs naturally, and are not shortened until they grow long enough to interfere with other growths. This is no doubt a quick method of bringing trees into bearing, and is probably necessary with trees on free stocks, as they nearly always are in America, and in a climate where growth is rampant. In thinning-out, the grower is advised to do the work, so far as possible, by means of numerous small cuts in all parts of the tree, rather than by sawing off a few larger branches. The invigorating effect of the pruning is thus well distributed, and the production of water-sprouts is reduced. Although so much is said about thinning-out in American books on fruit-growing, the illustrations always appear to English eyes to show trees which are very full of growths, but this may be merely the effect of the necessary reduction in size when such large trees are photographed.

---

* *Fruit-growing Projects*, by Fred C. Sears, Professor of Pomology, Massachusetts Agricultural College; pp. 383, illustrated. London: Macmillan and Co. Price 7s. 6d.

With regard to soil cultivation in orchards, three methods are recognised:—Clean cultivation, sod culture, and the cultivated strip system. Clean cultivation is seldom quite what we understand by the term here. The work starts with ploughing in early spring, and the land is kept clean and loose on the surface by frequent cultivation until the early part of July, when a cover crop of some kind is sown, or in some cases the land allowed to sow itself with grass and weeds. This cover crop remains during the autumn and winter, and is ploughed under in early spring. There are several reasons for this system, which seems to be well designed to suit the conditions prevailing. A cover crop is necessary in winter to prevent the washing away of soil by heavy rains, a need which is seldom felt in this country. It serves also to supply the soil with humus, and with nitrogen if a Leguminous crop is used, and also to check growth during the autumn with benefit to the fruitfulness of the trees. Active growth is most desired during spring and early summer, when it is assisted by cultivation. English growers might do worse than give this system a trial.

Sod culture, as practised in America does not mean grazing with stock. The grass is mown twice a year and spread as a mulch under the trees, where it eventually rots into the soil. This system obtains mainly in districts with heavy rainfall, and, when used in conjunction with the generous use of nitrogenous fertilisers, gives good results. The cultivated strip method is a compromise between the two plans just described. The strips on which the rows of trees actually stand are left in grass, and mown twice yearly as in sod culture. The alleys between the rows are cultivated during early summer, and then sown with a cover crop, as in the clean cultivation method. This saves the labour of hand cultivation close to the trees and seems to be a very sensible and economical system.

Spraying is considered by the author to be the most important single operation in the care of an orchard. Pruning, manuring, and cultivation, although important, are not so disastrous if omitted as is neglect of spraying. When one reads of the formidable list of pests and diseases with which American growers have to contend, one does not doubt this statement.

Strawberries are grown for market in America on the matted row system, which is generally condemned in this country; but then the beds are commonly cropped for one year only. The plants are set eighteen inches apart in the rows, and during their first season, when blooms are removed, the runners are allowed to root as they will; or, in what is called the "spaced row" system, they are arranged regularly about the parent plants. The following year, both the old and young plants bear heavily, after which the bed is usually abandoned. The method of littering the beds is interesting. Owing to the severity of the winters, a thick mulch of straw has to be applied in late autumn, covering the entire space, plants and all. In early spring, when the plants begin to grow, but before the growths become blanched, the mulch is opened slightly along the rows, but only just enough to allow the plants to push through. If the mulch is thick enough, weeds are suppressed, moisture is conserved, and cultivation spared, while the fruits, of course, are kept clean.

Other crops dealt with in this extremely well illustrated book are Peaches, Grapes (in the open), Raspberries, Blackberries and Loganberries. *M. G.*

NOTES FROM A WELSH GARDEN.

THE very vivid green of the glossy-leaved Sedum praealtum is always pleasant enough these dull days, especially on a dry wall where this rather tender species is safer. I once had several Sedums of this class, but they have all gone but this one, which seems fairly hardy in a sheltered place. It flowers tolerably well in spring, provided the season be sunny, but at its best it makes rather a feeble display compared with those blazing hedgerows of gold which make such a glorious show of colour in many gardens of southern Europe, even at this season. Still more beautiful as a foliage plant is S. Palmeri, the leaves of which are a cool, glaucous green that assumes a frosty sheen in winter. Then none can overlook that hardy stand-by, S. spathulifolium, one of the best of all Sedums for our gardens. In all its forms this American species is now delightful, whether the leaves and rosettes are large or small, blue-grey or rose-purple, or a bright blood-red. The crimson-flushed rosettes of S. compressum can also be attractive at this season, but last winter's frosts were too much for this fine species here.

Anemone Hepatica, both the rose and white forms, were flowering gaily before the New Year. But if a spell of wintry weather has temporarily checked their ardour, these cheerful things will be as pretty as ever so soon as milder conditions prevail. While one can welcome these Anemones as seasonable associates for the early Snowdrops, I am never so sure about the Primroses. These, in blue, purple, yellow and other tints flower so persistently from late November onwards that, while they seem to rob the spring of some of its rightful charm, they seldom look really happy as winter flowers.

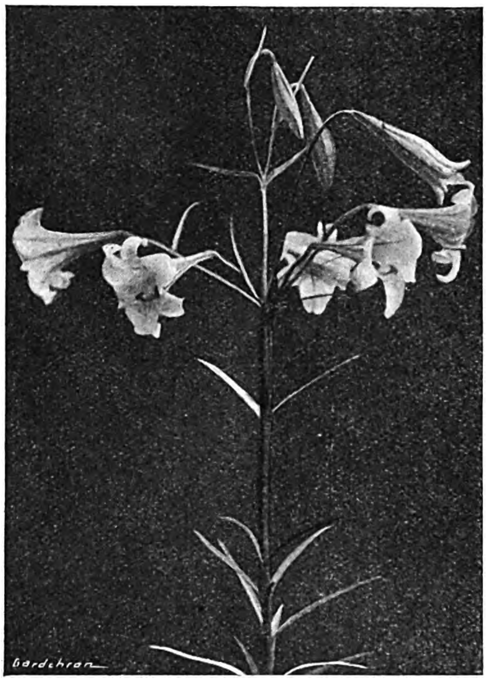

FIG. 34.—A SINGLE SPIKE OF LILIUM PHILIPPINENSE VAR. FORMOSANUM.
(see p. 63)

Vinca difformis, on the other hand, even if it is a southerner, fits into the tone of the hour with singular success. Its sharply-lobed, white flowers gleam with a cold, dead pallor in the shady places in which it delights, and if they are snubbed by frost, there are always plenty more to follow. I have not found this plant anything like so rampant as V. major or V. minor, and one wonders why it is not more often grown as a carpeter beneath trees, especially by those who take an interest in their winter gardens. Also delightful in the woodland undergrowth just now is the foliage of the hardy Cyclamens, their soft olive-greens often so attractively lined and clouded with emerald and silver. Then there are the crimson-tinted Shortias, the even more ornamental leafage of Galax aphylla, the deep green, bronze-tinted thatch of Lomaria alpina's close, over-lapping fronds, the rich, russet-tinted verdure of Gaultherias, and the vivid lettuce-green with which Helxine Solierolii covers a cool rock. These and a hundred others in a setting of brown leaves and rusty Ferns, do much to cheer the woodland gardener through the darkest days.

If those precocious Primroses are apt to "queer the pitch" for later on, even more flagrant is the behaviour of Ribes speciosum. This very handsome Gooseberry is often wont to believe that a mild November is the advent of spring, and to show it by immediately disclosing the tender green of breaking buds. But this time it has gone further and a large bush, quite in the open, is now entirely garbed in the fresh and tender leafage of April. Several degrees of frost have not injured its foliage, and this hearty Californian optimist, which is playing at being an evergreen, will, I have no doubt, bloom as freely as it always does at its appointed time.

In contrast to the autumn-fruiting Barberries, whose berries, which have been a virulent colour since the first frost, will linger on the leafless branches, is B. pruinosa. This very distinct and elegant shrub is not only an evergreen whose leaves are a lively, lustrous green with almost white underparts, but its fruits are now very attractive. These berries, which hang singly or in clusters on long stalks from the leaf axils, are not large, and they are black, but they are coated with a blue-white "bloom" which has that almost luminous quality common to some Grapes.

Erica arborea came into flower much earlier than usual, but this fine winter-flowering Heath does not bloom with such riotous prolificacy here, nor make such a shapely bush, as it does in gardens where there is a fuller exposure to light and air. It is inclined to get thin and straggly in the neighbourhood of trees and, being softer in leaf and branch, is actually more susceptible to frost than it is in places which have little or no shelter. At Bodnant there is a magnificent specimen which must be thirty to forty feet in circumference. It is standing on the open lawn, and does not appear to have suffered any injury from the disastrous frost of 1927-8. Yet there are shrubs of this species in the same district which, despite their more protected situations, were cut to the ground. Parallel instances showing the effect of environment upon the hardiness of shrubs are afforded by Veronica Hulkeana and Metrosideros robusta; These were destroyed last winter in my comparatively sheltered garden, yet neighbours who have them both growing quite in the open, and fully exposed to frost and cutting winds, did not lose a twig of either. Such plants doubtless enjoy the advantage of being drier should frost follow wet, but it is, I think, fairly evident that the explanation of their immunity may be found in the fact that they are harder in foliage and wood—more acclimatised—than those in what would appear to be kindlier surroundings.

Chimonanthus fragrans, which should now be delightfully sweet, both in the garden and indoors, was also among last year's casualties, hungry mice which barked the stem being the cause of its loss. But Eleagnus macrophylla can be very nearly as fragrant under certain conditions of atmosphere and this choice evergreen has, in addition, foliage of singular beauty. E. macrophylla is, however, not quite so hardy as one would like it to be. It is apt to lose a good many of its brilliantly silvered leaves here during severe frosts, and it does not produce those ornamental fruits one reads about. If it is my very light loam which is the cause of this failure, as some contend, and not the climate, the former appears to be conducive to the production of a generous and bright silveriness in the foliage.

The fact that Daphne Dauphinii (hybrida) which I noted as being in flower in November, is still (mid-January) carrying a prolific crop of blossom is worthy of mention. Had the winter been mild, this would not have been surprising, but we have had prolonged spells of frost (up to 10°), and a good deal of sloppy snow, and more frost on that. Yet this cheerful little winter-flowering evergreen is undaunted, its purple clusters being unblemished and deliciously fragrant. *A. T. Johnson, Ro Wen, N. Wales.*

THE YELLOW DAY LILIES IN AMERICA.*

(*Continued from p. 51*).

SPECIES AND VARIETIES.

THE species now available in the American trade are relatively few as compared with the named hybrids. They are all excellent plants and worthy of garden use, with the possible exception of the Tawny Day Lily. In the following text, the species will be described first, divided into the two groups, early and late flowering, and the hybrids will be likewise listed and similarly divided. Several of the hybrids have names that might suggest a specific character, as, for example, ochroleuca, Baronii, and luteola, but the crosses are recorded, so there can be no question.

EARLY-FLOWERING SPECIES.

There are four species that flower almost simultaneously, but with approximately the following order: H. Middendorffii, H. minor, H. flava, and H. Dumortieri. The season causes some variation, principally showing as an exchange in places of H. flava and H. Dumortieri.

The Amur Day Lily, Hemerocallis Middendorffii, Trauty and Mey., makes dense tufts of yellowish-green foliage about fourteen inches high, through which are borne the flowering stalks barely overtopping the leaves, The inflorescence is a crowded head surrounded by conspicuous bracts. The flowers are six to ten in number, opening successively. The colour is cadmium-yellow of a pure and luminous quality, contrasting well with such purple Tulips as Velvet King and the white of Aquilegias, particularly the double white A. vulgaris, and is almost identical in colour with the golden Wallflower (Cheiranthus Allionii). The almost scentless flowers are more cupped and less trumpet-shaped than those of most Day Lilies. The foliage is deciduous and in dry situations dies off rather early in the season. Seeds are produced abundantly, but propagation by division is more rapid. This plant is sold at times as H. Dr. Regel.

The Dwarf Day Lily and the Early Day Lily (Hemerocallis minor, Mill., and Hemerocallis Dumortieri, Morren) may be considered together, as aside from certain technical differences the first might be regarded as a diminutive form of the latter. The plants form low, dense clumps of about the same stature as H. Middendorffii, but produce inflorescences that are more spreading or overarching, and are branched and not capitate. The flowers are Lily-like in shape, deep chrome to cadmium-yellow, with brownish stains on the backs of the three outer segments. As all the segments are relatively narrow, the flowers are more starry in appearance than those of H. Middendorffii. These species seed rather sparingly but are easily propagated by division. The foliage is deciduous. H. Dumortieri is occasionally listed as H. rutilans or as H. Sieboldii.

The Lemon Day Lily, Hemerocallis flava, was named by Linnaeus in the second edition of the *Species Plantarum*, in 1762. In the first edition, published in 1753, he used the name Hemerocallis lilioasphodelus, which technically is the proper Latin name for this species. It is the familiar Lemon Lily of old gardens. Unlike the preceding odourless species, it is very sweetly scented. It forms loose clumps of dark green, arching foliage and spreads rather widely by underground stolons. The flower stalks rise about three feet in height, taller or shorter, according to the richness and moisture in the soil, and branch rather widely at the summit. The flowers are of exquisite Lily-like shape and are a clear lemon-chrome colour. The plant seeds somewhat sparingly, producing very large, almost globular capsules which contain a few rather large seeds. Increase by the removal of stolons is to be preferred. This species flowers more freely and is more content in moist soil than the preceding species, and is particularly lovely when planted near pale-lavender Irises.

There is a stronger-growing form known as flava major, which is even more desirable than the type because of its large growth and longer flowering season.

LATE-FLOWERING SPECIES.

The summer-flowering species now available, in their approximate order of flowering, are H. fulva, H. aurantiaca, H. Thunbergii and H. citrina. In beauty they are somewhat overshadowed by their hybrids.

The Tawny Day Lily, Hemerocallis fulva, L., is the Day Lily most widely distributed over the world. It forms dense clumps of strong-growing foliage and spreads by wide underground stolons too aggressively for general garden use. Its branching stalks rise as high as four feet, and produce flowers successively through July The colour varies somewhat, but is a tawny-red over the yellow of the petals and becomes most intense at the arrow-shaped zone which defines the yellow base of each segment. There is considerable difference in the pigmentation of H. fulva, with a predominance of paler forms. This plant is practically sterile and is propagated by division. The foliage is almost evergreen.

There is a double form usually listed either as H. disticha or H. Kwanso which is identical in all ways, save that it is later-flowering, blossoming well into August and flowering beautifully with white Phloxes and various Buddleias; there is also a form with variegated foliage. Various plants are to be obtained in the trade under the name of Orange Day Lily, Hemerocallis aurantiaca, Baker, all of which rather closely approximate the description of the species. The true species is very similar to H. fulva in its general habit, but is neither stoloniferous nor sterile. The bright orange flowers are large, opening so widely as to appear somewhat starry. It flowers during July and continues into August. As there are many flowers on the branched inflorescences, it makes a splendid display when the clump is well established and of some size.

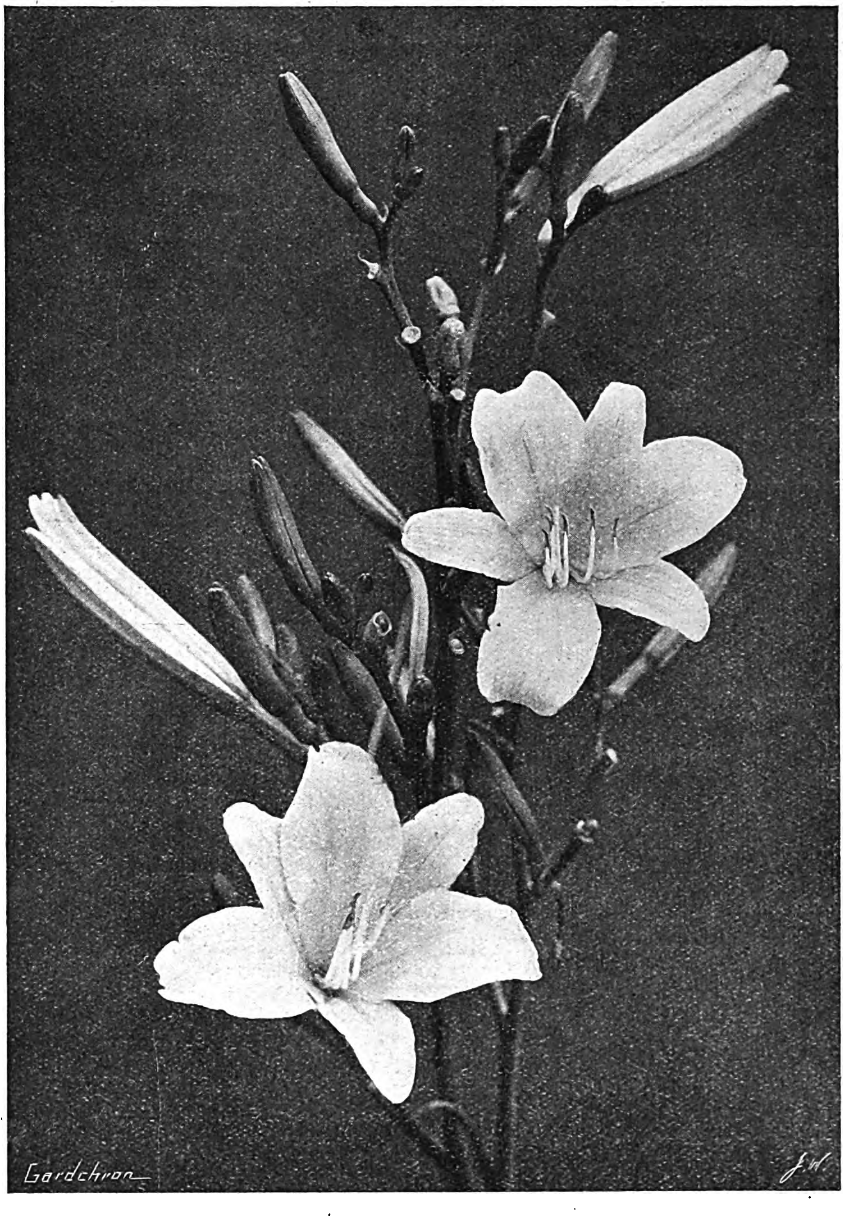

FIG. 35.—HEMEROCALLIS LADY FERMOY HESKETH.
(see p. 51.)

The plant most commonly received in place of H. aurantiaca is H. aurantiaca major, a dwarfer plant with flowers more similar in shape and pattern to those of H. fulva, but of a paler and more agreeable hue, as they possess none of the purplish quality that mars the rusty-red of H. fulva. Until this is well established, so that many flower stalks are produced in one clump, it is not especially showy in the garden, as its colour does not carry so brilliantly as the lighter yellows, but shows as an apricot-yellow. It is less tall, rarely exceeding two feet. As it makes considerable growth of evergreen foliage in the fall, it should be planted in a well-drained soil and given the protection of rather loose straw or litter. If it is left unprotected the leaves are so badly injured that the plant suffers in vitality. Like the type, this form is neither stoloniferous nor sterile.

---

* By B. Y. Morrison, Senior Horticulturist, U.S. Bureau of Plant Industry. Reprinted, in substance, from Circular No. 42, U.S. Department of Agriculture, Washington, U.S.A.

The Japanese Day Lily, Hemerocallis Thunbergii, Baker, is commonly described as "similar to H. flava, but later-flowering." Superficially, this is true, but even if they flowered together this plant would be differentiated by its more slender leaves and taller, more slender flower stalks, which are widely branched and bear flowers much paler and of a more greenish-yellow than those of H. flava. The flowers are sweetly scented, and during hot weather often open in the evening and last until the following evening, a tendency apparent in many of the summer-flowering varieties. The plant does not spread by stolons, but must be increased by division.

The Citron Day Lily, Hemerocallis citrina, Baroni, is a true evening blossomer, opening its flowers about 6 o'clock and closing them before noon the next day. In general habit it is much like H. Thunbergii, but the inflorescence is less branched. The flowers are larger, longer, and more trumpet-shaped. They are slightly deeper in hue, and are even more delightfully scented. The foliage is semi-evergreen. The plant is reported to be half-hardy, but has endured without protection in the writer's garden (near Washington, D.C.). It is not showy in the border until it has become a fair-sized clump.

None of the late-flowering species should be judged from the flowering of newly-planted roots. As their increase is less rapid than the early-flowering species, it is the usual nursery practice to divide them into single fans of leaves. These require several years before the clumps become fully established and strong enough to show six or more stalks of bloom with a full quota of flowers on each.

(*To be continued.*)

THE GENUS PRIMULA.

(*Continued from p.* 34.)

IANTHINA (Balf. f.). Violet P.
(Candelabra.)

A BEAUTIFUL, robust, deciduous perennial species with a tuft of oblong or egg-shaped leaves from six to ten inches long, rounded at the tip, and tapering at the base into a long, winged stalk; margins furnished with sharp, curved teeth; both surfaces pitted with glands which exude a yellowish secretion—underside pale. Flower stem up to two feet tall, stout, coated with sulphur meal at the nodes formed by the umbels, which number one or two, and are placed one above the other. The numerous blossoms are of an intense violet colour, with broadly-heart-shaped or rounded, notched lobes, with at times a tooth in the sinus, and measure about one inch across; tube cylindrical, dilated upwards, with a ring in the throat, smooth outside, downy within. Flowers in July.

Grows near Sandakphu, in the Sikkim Himalayas, at about 11,500 feet above sea-level.

Culture: Good fibrous loam and peat, in a damp, open spot, should suit this species.

INVOLUCRATA (Wall.). Involucred P.
(Farinosae.)

A beautiful deciduous, non-mealy, perennial species of tufted habit, with elliptic-ovate, oblong-cordate, or rounded, blunt, leathery leaves tapering to a short or long stalk, in all one inch to three inches long; margins entire or furnished with obscure teeth. Flower stem four to twelve inches tall, bearing a loose umbel of three to six white blossoms on stalks about three-quarters-of-an-inch long. Corolla five-eighths-of-an-inch to three-quarters-of-an-inch across, divided into five flat, broadly heart-shaped, notched lobes; tube cylindrical, yellowish, twice as long as the calyx, with a ring in the mouth. Flowers in June. Introduced in 1848.

Illustrated in *Journ. Roy. Hort. Soc.*, Vol. XXXIX, 1913.

Grows in damp, half-shady spots, on the mountains of northern Europe, northern Asia and arctic America, reaching an elevation of 15,000 feet above sea-level in the Himalayas.

Culture: It succeeds in good loam and peat in a damp, shaded position.

IRREGULARIS (Craib.). Irregular-leaved P.
(Petiolaris-Sonchifolia.)

This plant is one of the many species, or perhaps, microforms, which connect P. petiolaris with P. sonchifolia. The stout, perennial rootstock produces a tuft of thin leaves about six inches long, with elliptic, oblong-elliptic or elliptic-egg-shaped, rarely oval or oval-lance-shaped blades, one-and-a-half inch to three-and-a-half inches long, somewhat abruptly narrowed into a narrowly-winged stalk; margins irregularly and sharply toothed; both surfaces nearly smooth. Flowers on stalks equalling or shorter than the leaves, coated upwards and on the calyces with sulphur-yellow meal. Corolla about three-quarters-of-an-inch across, with broadly oblong or egg-shaped segments sinuately-lobulate at the tip; tube cylindrical, about five-eighths-of-an-inch long. The colour of the blossoms is not recorded, but is probably some shade of purple. Flowers in March. Not in cultivation.

Grows in damp, shady places near Singaleelah and Nathu-la, in western Sikkim, at from 9,000 feet to 14,000 feet above sea-level.

Culture: It might be grown successfully in good loam and Oak leaf-soil, in a damp, shady situation. *A. W. Darnell.*

(*To be continued.*)

THE STATUS OF MECONOPSIS DAILEYI.

I HAVE had occasion, in the preparation of a revision of the genus Meconopsis, to study the taxonomy of M. betonicifolia, Franch., and M. Baileyi, Prain. Since the introduction to this country by Captain Kingdon Ward of plants under the name of M. Baileyi there has been considerable controversy as to the true identity of that species. It has been the custom in some gardens to grow these plants under the name M. betonicifolia, and it is the purpose of this note to record the conclusions arrived at after careful study of herbarium specimens and cultivated plants.

The original description of M. betonicifolia was based on specimens collected by Delavay in Yunnan which, as figured and described, have a glabrous ovary. Mr. George Forrest collected specimens from the type locality, and while some agree with Franchet's figure and description, others have the ovary slightly hairy.

During his 1924-25 expedition, Captain Kingdon Ward communicated plants from Lunang, Tibet, which had a densely hairy ovary, and which were referred to M. Baileyi, since they agreed with the incomplete description of that species, and were collected from the type locality. It is necessary to remember that Sir David Prain had very inadequate material on which to base his description, and no representation of the habit was possible. Since the acquisition of Ward's specimens, it is possible to determine with certainty the affinity of the species. There is no doubt that it agrees very closely with M. betonicifolia. Separation of M. Baileyi and M. betonicifolia has been attempted from vegetative characters, and the relative lengths of the style, but all these characters have proved unreliable. The separate identity of M. Baileyi, then, depends on whether the densely hairy ovary ascribed to it is constant. Ward has, however, collected specimens from a neighbouring locality on which the ovary is only sparsely hairy. Those specimens form an undeniable link with forms having glabrous and sparsely hairy ovaries collected by Franchet and Forrest.

That the two plants are conspecific seems evident, and what has been called M. Baileyi in our gardens may, at most, only be regarded as a geographical form of M. betonicifolia. The present extent of our knowledge indicates that the plants from Lunang are not worthy of specific rank. Horticulturists with experience of this genus realise how prone many species are to variation, and will probably agree that the inconsistency existing in the species under review can be explained as the result of natural variation. *G. Taylor, British Museum (Natural History).*

ADDITIONS TO THE LINDLEY LIBRARY.

THE following books and pamphlets have been deposited in the Royal Horticultural Society's Lindley Library, during the half-year commencing July 1, 1928.

HOME CORRESPONDENCE.

Pyracantha Rogersiana.—My apologies are due to Mr. Coltman-Rogers for spelling Rogersiana with a "d," and I must plead carelessness. I hope, however, that the adding of a "k" to my own name arose from what I pleaded rather than retaliation. His note on this plant was interesting, and his advice to use it as a hedging plant might well be taken. *William Acworth, Chobham.*

Soil Sterilisation.—I am writing to compliment your correspondent, Mr. L. J. Moore, on his excellent improvisation for soil sterilisation. Because of its simplicity and economy, I consider it by far the best contribution to the subject it has been my privilege to see described, at least, so far as it affects the "small fry." In these gardens we have for some years used a discarded "canning equipment," but as a result of your correspondent's description of his methods, I find we can improve somewhat on our existing mode of procedure. A further point I should like elucidating is, which is the best method to adopt, steaming or baking? In this district we are in a very embarrassing position, having two authorities, each blessing the two respective methods. Mr. Shewell-Cooper has put down at the County Horticultural School a most efficient baking plant, and during the past season, at a conference of growers, it was brought to their notice and fully explained. Mr. Shewell-Cooper most emphatically declares that baking gives the best results, because of the fact that it leaves the soil in the best mechanical condition for the resulting crop; and I well remember as a student gardener at Kew, hearing the late Mr. Watson say that "the texture of the soil was more important than the quality." Mr. Shewell-Cooper has explained the construction and use of his plant in *The Fruitgrower*, and it has been widely commented upon. Quite recently, Professor Holmes Smith, the Government mycologist for this area, delivered a lecture before our local horticultural society, in which he advocated the steaming process in preference to baking, because of the danger in baking of destroying the beneficent bacteria, as well as the destructive type, and this seems to me rather a point in favour of steaming; and, further, is it possible to hope that with the steaming process certain plant foods may be rendered soluble and retained, whereas in baking they might be destroyed or given off as gas? With judgment, the texture of the soil need not be prejudiced to any degree as a result of steaming. In your excellent review of the subject in *The Gardeners' Chronicle* for October 1, 1927, page 259, it was the steaming process that gave such excellent results. Further testimony from experts on the two methods would be welcomed by many of your readers. *T. A. Summerfield, The Gardens, Alderley Park, Chelford.*

——I was interested to see a recent note on Soil Sterilisation in *The Gardeners' Chronicle*, but agree with Mr. John Butler, of Kindlington, that steam sterilisation is by no means the simplest, most effective and least costly. We have, at the Cheshire School of Agriculture, carried out experiments on Soil Sterilisation by all known means: (1) By chemicals of various kinds and types; (2) by a special machine which operates on a principle similar to that described by Mr. L. J. Moore (see *Gard. Chron.* of January 12) only on a larger scale; (3) by steam pressure from our dairy boiler (a similar scheme to Mr. Falconer's (see *Gard. Chron.* of October 1, 1928); and (4) by baking in a brick steriliser of the type used by Mr. Priestner and other Baguley growers. In our experience, this last method has proved much more satisfactory than any of the others. Our reasons for saying so are as follows: (a) The apparatus is easy and cheap to build—the materials for ours, which deals with three tons of soil at a time, cost only £12, and it was built by a semi-skilled man. Similar brick sterilisers for smaller quantities of soil could be built for £8 or £10. (b) In the steam method of sterilisation described by Mr. Falconer, the cost to the ordinary man is prohibitive, as the boiler would have to be bought especially for the purpose. Soil sterilised by steam is very liable to become sodden; I have, on occasion, seen it brought out of a steam steriliser in the form of mud. Such treatment ruins the texture of heavy soils. Further, a few days have to elapse before soil which has been sterilised by steam is sufficiently dry to use and this is often inconvenient. (c) The baking method described in our leaflet (a copy of which I shall be pleased to send to any interested reader) does everything steaming does, and yet the soil emerges in a perfect condition for sowing seeds, and needs no special preparation—it can even be used warm! *W. E. Shewell-Cooper, Horticultural Superintendent, Cheshire School of Agriculture, Reaseheath, Nantwich.*

Twin-flowered Cypripediums.—With reference to these, mentioned in your columns of December 8 (p. 457) and December 29, 1928 (p. 510), I have a plant here of Cypripedium insigne carrying thirteen flowers on twelve stems, one stem with two perfectly formed flowers about two inches apart. *J. E. Jones, Highfields Gardens, Marlow, Bucks.*

Dangers from Poisonous Plants.—The deaths of eleven valuable farm animals from Yew leaf poisoning near Dingwall, the county town of Ross-shire, the other day, reminds us of the possible dangers from this source. We have a number of poisonous plants in the British Isles, the principal of which are Aconite (Monkshood), Belladonna, Arum, Box, Black Bryony, Broom, Laurel, Cherry, Foxglove, Cowbane, Hemlock, Marsh Marigold, Sorrel and Ivy. Botanists have also introduced from abroad many plants which are cultivated for their medicinal value. The poison is more active among these plants in spring and summer, when the plants are green. Many of the demesnes of our county mansions, contain areas of grass surrounded by copses, thickets, or plantations, containing Yews, Laburnums and Rhododendrons, and where these exist precautionary measures are necessary. Farm stock is often put upon these grass areas, and although animals do not readily eat the poisonous shrubs named when the grass is good, there is always a danger present. All such beltings should be carefully fenced off from grass areas whereon grazing stock are allowed to roam. *W. K.*

COLONIAL CORRESPONDENCE.

NEW MOON SOWINGS.

UNDER this heading, in the issue of *The Gardeners Chronicle* for August 4, 1928 (p. 97), the writer evidently is somewhat credulous as to the results of such practices. Many scientific authorities have definitely stated in the past the folly of adhering to the moon theory as a guide to sowing seeds, yet I can prove conclusively that all unbelievers of the theory are wrong. It not only applies to the germinating of certain seeds, but has a marked influence on seed production, when pollenating is done within a few days of the full moon. The theory as adopted by me for the last forty years, applies only to the raising of certain seeds under natural conditions. I sow Chrysanthemum seeds in August or September each year. The seeds are sown about ten days before full moon; should the weather be favourable, nearly all the seeds have germinated by the full moon. If the weather is not favourable (cold changes, etc.), they remain in the boxes until the next full moon. A few may remain until the third, or even fourth, before germinating. By adopting this method I seldom have any damping-off; this would probably be otherwise if the seeds were sown under artificial conditions. This rule applies to many kinds of seeds. I have had Roses germinate intermittently for five or six months, and invariably all came through within a few days of each successive full moon. I have reason to believe that many gardeners may enlighten scientists on the fact that the moon plays an important part in the periodical germination of many kinds of seeds, including seasonal weeds, etc., which always come up and flower, as near as possible, the same time each year. The writer has observed also the larger amount of pollen in flowers on, or about, the full moon, compared with other times, and further, the activities of bees and other fertilising agents. *Thomas W. Pockett, Victoria, Australia.*

FOREIGN CORRESPONDENCE.

ASCLEPIAS TUBEROSA.

IT was while rambling through open country, some thirty miles from New York city, that I obtained my first glimpse of this beautiful Swallow-wort in its native habitat. It was growing in great clumps on a rather dry, sunny slope, and the marked superiority of the wildings over plants seen cultivated in British gardens was very apparent. The gorgeous, bright orange-coloured flowers were conspicuous, even when viewed from a distance, so much so that they had attracted the attention of passing motorists who were despoiling the countryside by gathering great armfuls to carry away.

Known throughout the north-eastern United States by the names of Butterfly-weed and Pleurisy-root, this plant varies in height from eighteen inches to four feet six inches. The stems are very leafy and rough with hairs, much branched towards the apex, and bearing the flowers either in umbels arranged to form a terminal corymb, or in racemes scattered along the branches. The leaves vary in shape from linear to oblong-obvate, and they are mostly scattered and sessile, or nearly so. Unlike many members of the genus Asclepias, this species has no milky latex.

A rich light soil and a sunny, sheltered position, provide the conditions necessary for the successful cultivation of this plant in Britain. In most localities protection of some description may be essential during severe winter weather. It may be propagated by division in autumn or spring, or by sowing seeds under the protection afforded by a cold frame during the spring. *T. H. Everett.*

MARKET FRUIT GARDEN.

On adding up my rainfall figures for the year 1928, I am surprised to find that the total amounts to so much as 32·66 inches, some two-and-a-half inches over the average for the district. The glorious summer gave one the impression of a very dry year; but the drought lasting through July, August and September was largely balanced by the very heavy rainfall of January, October and November. Fortunately, 1928 closed with a fairly dry December (rainfall 3·12 inches), as a result of which the land has been unusually sound throughout the winter so far, no doubt a very favourable condition for fruit trees and bushes. Such work as winter spraying, pruning, and the application of manures, has made good progress.

Spraying at High Pressure.

For this season's spraying, some improvements and additions have been made to the appliances. A three-throw pump has been substituted for the old two-throw machine, which has given some nine years of good service. With the new pump it is easy to supply four nozzles at a pressure of between 200 and 300 pounds per square inch. Most growers now realise that pressure is important. Some washes, notably the tar distillates used in winter, give better results if applied at high pressure; while, naturally, the work is done more thoroughly, easily, and quickly with a large cone of spray which reaches readily to the tops of the highest trees. A man can wet a tree all over in very much less time if he has plenty of pressure behind the nozzle. As a further means of speeding up the work, another 100 yards of steel portable main piping have been added to the plant. This allows of two main pipes being laid down instead of only one, so that spraying is not interrupted while the piping is moved. So soon as the sprayers have finished all the trees they can reach from one main, they shift their hoses to the next, which has been laid down for them in advance. In this way there is a saving of some two hours of shifting work per day, giving about a day's extra actual spraying in a week. Rapid work is obviously essential in spraying on a large scale. In winter there is none too much weather suitable for the operation, and the most must be made of such opportunities as occur. In spring and summer, when spraying to prevent Apple scab, it is even more necessary to get over the ground quickly, in order to get the spraying done at the correct stages of vegetation.

Apple Capsid.

The tar distillate washes are curiously uncertain in their effect on Apple capsid. It used to be stated that they gave no control at all of this troublesome pest, but in some recent trials good results have been obtained, while in others the treatment has failed. During 1928, Mr. F. V. Theobald made trials at two centres, one near Worthing and the other at Selling, Kent. In both cases the wash was applied at ten per cent. strength and with plenty of pressure. The result at Worthing was markedly beneficial. Not only were the foliage and growth much more satisfactory on the sprayed than on the control trees, but there was a decided increase in the proportion of saleable fruits. Trees in the same plantation, heavily sprayed with hot lime-wash, were hopelessly injured by capsids. At Selling there was a similar improvement in foliage and growth due to the spraying, but not the same benefit to the fruits. The reason for this is probably that the set of fruits was very light, so that the small crop was greedily sought after by the much reduced number of capsids. These results are important, because it has hitherto been the general experience that, in the south and south-east, tar-distillate washes have been useless against capsids, while in the west they have often been found to give considerable control. Why the result should be so uncertain has yet to be explained. It may be because the tar-distillates are not stable and capable of standardisation; or perhaps it is due to variation in conditions following spraying. The fact that these washes do, at times, control capsids is hopeful, because it will no doubt stimulate chemists to strive for improvements which will make them more effective. Already, at the Long Ashton Research Station, a wash has been prepared from high-soluble tar-distillate which, so far as it has been possible to test it at present, gives a better control of capsids than the ordinary commercial washes hitherto available.

It is most desirable that a winter wash to control capsids should be found, because it is exceedingly difficult for growers to deal with both capsids and scab by spraying around the time of flowering. Both troubles call for treatment at the same time and with different washes which cannot effectively be combined, and which need different methods of application.

The present position is that, while tar-distillate washes are uncertain in their effect on capsids, they are well worth using against this pest, the Long Ashton wash giving the best hope of success. In any case, winter spraying with tar-distillate is excellent as a preliminary stage in the campaign against capsids. In the Kent and Sussex trials mentioned above, a considerable proportion of the fruits was clean at first, but more of them became marked by the insects as the season advanced. It may be assumed, therefore, that, if the winter spraying had been followed up by one or two applications of nicotine and soap wash, before and after flowering, the result would have been excellent. The winter spraying gives the great advantage of sound foliage for a start, largely because it controls aphides and Apple suckers, thus making the work of subsequent sprayings for capsids easier and more effective.

The above remarks apply only to the Apple capsid. In one of the trials the green Currant capsid was not affected by spraying with tar-distillate at six per cent. strength.

Unpleasant Work.

People often remark that fruit-growing must be an ideal occupation. To the grower himself it may be so, but his workers are called upon to carry out many tasks that are most unpleasant. Take the present winter's work on my own place, for example. For about a month most of the hands were engaged in repairing old drains and laying new ones, miserable and heavy work in the cold and wet conditions prevailing. After this they went on to the mixing and distribution by hand of several tons of chemical fertilisers, including calcium cyanamide, which made them black all over and burnt the skin rather badly. Several raw and swollen arms were the result. A light and narrow manure distributor that can be drawn between closely-planted trees is badly needed. Now the men are engaged, whenever the weather is favourable, in tar-distillate spraying, another job which is painful for the skin and injurious to the clothes. One does what is possible in the way of providing overalls and plain lanoline to apply to the face and hands, but considerable discomfort has still to be endured. I think the last straw would be added if dry dusting succeeded liquid spraying.

Deep and Shallow Soils.

During draining operations this winter, I have realised fully how very shallow my soil is in places. In some cases there is not more than nine inches of good soil over the unweathered subsoil, much of which is of a most undesirable character. Many of my difficulties are due to this condition, but for all that, I should hesitate to shift to land such as is commonly considered to be most favourable for fruit-growing. I have always been an advocate of deep, well-drained soils for fruit trees, but I am beginning to doubt whether these give the best financial results. Certainly, such land suits the trees, which make wonderful growth; but in many cases they give fruits of poor colour. For some crops this is not an important point, but for dessert Apples colour is a selling factor of the greatest value. Mine is dessert Apple land; I ought not to grow anything else. No doubt there are soils that are deep and yet give the restricted growth which makes for fruitfulness and high colour—the clays of West Sussex, for instance—but they are not easily found. I am not at all sure that the deep brick-earths and other free-working loams generally considered to be ideal for fruit-growing are not more desirable for the nurseryman than for the commercial grower. *Market Grower.*

FRUIT GARDEN.

CORDON PEARS.

Pears are the most capricious of all the hardy fruits, and unless conditions are very favourable indeed—a well-drained and not too heavy loam in a warm situation, sheltered from the east and north winds—one can never be even moderately sure that any one of the choice varieties will be a success until it has been tried, and even then a wet and cold season may reduce it to below the level of a Pitmaston Duchess. For instance, after the poor summer of 1927, Doyenné du Comice and Beurré Superfin were quite good with me, although the latter was much russetted, but Emile d'Heyst, Le Lectier, Conference and Louise Bonne of Jersey were little better than Turnips. Hence the charge of caprice against Pears, and partly on that account I find a row of cordon Pears one of the most interesting features in the garden. Some Pears, like Catillac and Clapp's Favourite, attain a large size by August, while some, notably Olivier de Serres, Joséphine de Malines and Winter Nelis, are not much larger than Walnuts then, and yet weigh a quarter-of-a-pound or more each at the end of October.

I have mentioned cordons partly because of the greater number of varieties which may be grown in a given space, and partly because with bushes or pyramids, one is apt to get too many of one variety, especially when two or three are in season at the same time, as will generally happen at the height of the Pear season—mid-October to mid-November. With thirty cordons in twenty-five varieties, one can have a fairly well assured succession in a moderately good season from August to April inclusive. Of those varieties with an extended season, notably Joséphine de Malines—often a slow bearer—Olivier de Serres and Easter Beurré, one is not likely to have too many fruits, and bushes may be more useful than cordons. The same applies to stewing Pears.

The ground should be well worked, a month before planting, if possible, applying a dressing of bone-meal and decaying vegetable matter rather than manure. It is obvious the site should be chosen carefully and, if away from a wall, a row of cordons should run from south to north. A catalogue should be studied with the help of an experienced friend unless, which is still better, the planter has the experience himself. In any case, he will do well to learn anything he can from his neighbours as to the vagaries of Pears in the locality. For supporting the cordons, six to eight feet Bamboos, held in position by a strained wire, should do for the first summer, perhaps for two, but later they will need stout posts, not too far apart, with two or three wires, the Bamboos being lifted until the trees attain their full length, which, of course, they will not all do at the same time. It is assumed for this purpose that the cordons will be planted diagonally at two feet apart.

If the trees are not planted by the middle of December, it is doubtful if anything is lost by not planting them before the end of February, when roots begin to be active and the soil less cold. If later than this, they need careful attention in a dry spring. *A. P.*

VEGETABLE GARDEN.

PEAS FOR EARLY SOWING.

While I would recommend the sowing of early Peas in boxes and planting the seedlings out later, especially on unkind soils, there are some climates and districts where the conditions are suitable for sowing seeds out-of-doors, if facilities for raising the plants under glass are not available; the old method of sowing seeds out-of-doors in the autumn is seldom practised now. Successful results may, however, be expected with some degree of confidence, if seeds of the round-seeded varieties, such as the Pilot, or Superb, are sown in light soil in a warm, sheltered position; but if such a situation is not available, and particularly if the soil is heavy in nature, it is better to defer the first sowing until the latter end of February or the beginning of March; even then it is courting disaster if the soil is not in the right condition to receive the seeds.

In specially favoured places, such varieties as Pioneer, Laxtonian, Eight Weeks and Little Marvel, should succeed if the weather conditions are suitable for quick germination, and to facilitate this they should be sown in drills and covered with a mound of sand three inches deep, while if wattle hurdles may be placed around the plot, these should ward off the cold, cutting winds which are so disastrous to early Peas. In some gardens there are narrow borders against the sides of glasshouses, and against low walls, and where these exist there should be little trouble experienced with early-sown Peas; most of the varieties catalogued by the leading seedsmen for early sowing are suitable for such positions. I have, however, come to the conclusion that it is much safer, provided a glasshouse is available, to raise all early Peas in boxes. By so doing, success is assured, fewer seeds are required, germination is much quicker, and, if the plants are grown on quite hardily, much better crops result, with the added advantage that the very best Marrowfat varieties may be grown.

To produce early crops under glass, such varieties as Eight Weeks, fifteen inches, and Early Giant, three feet, may be sown in November and early December, and the seedlings should be ready to plant out in cool houses, pits or frames, early in January, to produce a very profitable crop. Further sowings of the same varieties, together with Pioneer, may be made in January, and if the seedlings are grown under cool conditions they should provide good plants for planting out on a warm border in early spring, to follow those in the houses and frames. It is necessary to harden the plants well before they are planted out in the borders; this may be accomplished by standing the boxes in a well-sheltered corner. When they are planted, some twiggy sticks placed along the rows should afford the seedlings some shelter.

Further sowings in boxes should be made early in February. For this purpose the variety Witham Wonder may be sown, for it has proved very hardy with me, and also very prolific, while, being dwarf, it does not require much space. At the end of February such varieties as Bedford Champion, early, with Duke of Albany, and Alderman, of the second-early and taller varieties, may be sown, followed in March by that fine variety Admiral Beatty, which, provided it is of a good stock, is one of the best Peas in cultivation. If the variety Early Superb is sown out-of-doors at the same time as the last sowing is made in boxes under glass, it should afford a good succession to the latter. When the seedlings of Early Superb are showing above ground, seeds of Lancashire Lad (two feet) may be sown, to be followed by other suitable varieties at intervals of ten days until June 21, which is usually late enough for the sowing of Pea seeds in most districts. While the varieties I have enumerated above have proved good with me, it is well-known that some varieties do better in one district than in another; it is therefore advisable to sow only proved varieties in bulk, trying others in small quantities.

Boxes four inches deep are suitable receptacles for the Pea seeds, while the compost should consist of two parts loam, one part spent Mushroom-bed manure, and one part leaf-soil. Seventy-two pairs of seeds are best sown in each box (if one foot wide by two feet long), as the soil adheres better to the double root-system, and the plants grow better when planted out if some soil is attached to the roots. Another method is to sow the seeds in long, narrow boxes, wider at the bottom than the top, and with a false bottom supported by wires; when the wires are cut the whole contents of the boxes may be dropped in their places in the prepared trench, without any root-disturbance. When planting Pea seedlings draw a ridge of soil up to each side of the rows, and then place the sticks in position; very little further attention will be required until the Peas are ready to pick, other than examining them occasionally, in case of depredations by birds and insects, and attending to stopping and pinching out side-shoots if exhibition pods are required. All ground for Peas should be prepared well. The soil for early Peas should be trenched, but the best method of all is to plant the Peas in ground previously occupied by Celery, digging it well before planting. *Allan Falconer.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting of this Society, held on January 4, 1929, the members of Committee present were:—Messrs. H. Astley Bell (in the chair), J. B. Adamson, A. Burns, A. Coningsby, A. Keeling, D. McLeod, W. J. Morgan and H. Arthur, Secretary. Mr. D. Pitts was invited to sit with the Committee.

Awards of Merit.

Cypripedium Kestrel (*C. nitens Leeanum Bectoniae* × *C. Swallow*) and *C. Waratah var. Chieftain* (*C. Euryades, Carter Place var.* × *C. Swallow*). From Captain W. Horridge.

Cypripedium Elaine (*C. Mona* × *C. Leeanum*); *Odontioda Leonatus* (*Cochlioda Noezliana* × *Odontoglossum Thompsonii*); and *Adaglossum Pittsii* (*Ada aurantiaca* × *Odontoglossum Pescatorei*). From Messrs. A. J. Keeling and Sons.

Cypripedium Lucinda var. Martin David Ramsay (*C. Lucernale var. Lady Patricia* × *C. Alcibiades var. Illustris*). From Mrs. Bruce and Miss Wrigley.

Cypripedium New Year (*C. Christopher* × *C. The Ghurka*). From J. B. Adamson, Esq.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged a group to which a Gold Medal was awarded. Cypripediums in variety, including C. Minotaur, C. Perseus, C. Thisbe, C. Olympus var. The Chairman, C. Curlew, C. Bedfordae, C. Stamperland, C. Niobe superbum, C. Hercules, C. Memoria var. F. M. Ogilvie, and C. Carola. Odontoglossum crispum, O. Canopus and O. Illustre var. superba; Odontioda Colinge var. Ruth; Brasso-Cattleya British Queen, and fine specimens of Vanda Amesiana, were among his outstanding subjects. Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, staged a group which was awarded a Large Silver Medal; it contained grand examples of Cypripedium Alcibiades var. Illustris, C. bourtonense, C. March Along, C. The Pearl var. Lady Blanche, C. Invincible and several Bridge Hall Cypripedium seedlings, notably C. Actaeus var. Lady Greensleeves, C. Queen Velma var. Queen Ena, C. Helsa var. Astrid, C. Carlo var. Young Pretender, C. Mario var. Leonora Cook, C. Ruzzie var. Santler, C. Caractacus var. Janet Coffin, and C. Britain's Monarch var. George.

Messrs. A. J. Keeling and Sons were also awarded a Large Silver Medal for a group containing Cypripediums in variety, including C. Elaine, C. F. M. Ogilvie var. The King, C. Perseus, C. Goldylocks, C. Makeda, C. Nesta II, and C. Prince Albert, together with Odontioda Leonatus and O. Brilliant, and the rare Adaglossum Pittsii; while Captain W. Horridge (gr. Mr. A. Coningsby), Bury, and Mr. D. McLeod, Chorlton-cum-Hardy, staged Cypripediums in variety.

At the meeting held on January 18, the members of Committee present were:—Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, J. Evans, A. Keeling, D. McLeod, W. J. Morgan and H. Arthur (Secretary).

Awards of Merit.

Cypripedium Sumurun var. Snowball; *C. Elidia* (*Elise II* × *Idina Leeana*), and *C. Elidia var. Cosmos*. From Captain W. Horridge.

Cypripedium Eurydore (*Euryades splendens* × *Commodore*), and *C. Mona var. Dolcis*. From J. B. Adamson, Esq.

Cultural Certificate.

To Mr. A. Burns, for Calanthes.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged a group to which a Gold Medal was awarded; it contained Cypripediums in great variety, including C. Roundhead, C. Lady Evelyn James, C. Viking, C. Commodore, C. Mrs. F. Sander, C. Madame Jules Hye, C. Thunderer, and C. bourtonense magnificum, together with Odontoglossum aspersum, Sophronitis grandiflora, Oncidium tigrinum, and Epidendrum Wallisii.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, were also awarded a Gold Medal for a magnificent group of Calanthes, notably C. William Murray, C. Bella, C. Bryan, C. Kenneth, C. Veitchii and C. vestita oculata rubra.

Mr. John Evans, Colwyn Bay, received a Large Silver Medal for a group in which Cypripedium F. M. Ogilvie, C. Eurybiades var. The King, C. Makeda, C. Anita compactum, C. Alcibiades var. Illustris, Odontoglossum eximium and O. Alvara, Odontioda Lorna and O. Patricia, were prominent, while Messrs. A. J. Keeling and Sons, Bradford, staged Cypripedium Ena, C. Argo, C. Merlin and C. Prince Albert, and Odontoglossum regale var. splendens. Mr. D. McLeod, Chorlton-cum-Hardy, showed Cypripediums in variety.

The next meetings of this Society will be held at the Houldsworth Hall, 90, Deansgate, Manchester, on February 1 and 15, 1929. The Committee will sit at 12 o'clock noon each day.

ROYAL HORTICULTURAL.

The following awards have been made to the undermentioned vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Carrots.

Awards of Merit.

(19) *Early Guerande*, sent by Messrs. Speed, Evesham; (21) *Perfection*, sent by Messrs. R. H. Bath, Wisbech; (48) *Nantes Selected*, sent by Messrs. Zwaan and van der Molen; (32) *Carenton*, sent by Messrs. Nutting and Sons, London; (99) *James' Intermediate*, sent by Messrs. James Carter and Co., Raynes Park; and (96) *Intermediate Selected*, sent by Messrs. Dobbie and Co., Edinburgh.

Highly Commended.

(6) Paris Market, sent by Messrs. Olsen, Denmark; (8) Early Gem, sent by Messrs. W. H. Simpson; (17) Oxheart (6184), sent by Messrs. C. C. Morse and Co., San Francisco; (61-64), Chantenay (6373, 5184, 57-47, 57-25), sent by Messrs. C. C. Morse and Co., San Francisco; (14-15), Scarlet Horn, sent by Messrs. C. C. Morse and Co., San Francisco, and Messrs. Webb and Sons, Stourbridge; (12) Early Horn Improved, sent by Messrs. James Carter and Co., Raynes Park; and (9, 11) Early Scarlet Horn, sent by Messrs. W. H. Simpson, and Messrs. Morris, Birmingham.

Commended.

(22-29, 31) Amsterdam Forcing, sent by Messrs. Zaaizaadvereeniging, Nunhem; Messrs. Zwaan and van der Molen; Messrs. Atlee Burpee and Co., Philadelphia; Messrs. Sluis and Groot, Holland; Messrs. Spruijt, Holland; Messrs. Harrison, Leicester; Messrs. Daehnfeldt and Jensen; and Messrs. E. Benary, Germany; (13) Dutch Early Short Scarlet, sent by Messrs. Sluis and Groot. All the foregoing commended varieties were considered to be alike.

PARKS AND BOTANIC GARDENS SUPERINTENDENTS.

The annual meeting of the Scottish Branch of the Parks and Botanic Gardens Superintendents' Association was held in the City Chambers, Dunfermline, on January 12. Prior to the meeting, the members received a very cordial welcome from Provost Wilson, and were afterwards entertained to tea by the members of the Town Council.

Mr. William Besant, Director of Parks, Glasgow, occupied the chair, and it was unanimously agreed that the branch be continued during the ensuing year.

Mr. Besant, Glasgow, was re-elected President, and Mr. Jeffrey, Edinburgh, and Mr. Clark, Aberdeen, were re-elected Vice Presidents;

Mr. Campbell Perth being appointed Secretary and Treasurer. The members of Committee elected were Mr. Lauder, of Coatbridge; Mr. Campbell, of Helensburgh; Mr. Fleming, of Paisley; Mr. Brown, of Rutherglen, and Mr. Graham, of Carnegie Park, Dunfermline. It was agreed that the next annual meeting be held in Perth in April, 1930, and that, a meeting be held in Perth, in April of this year, to appoint delegates to attend the annual meeting of the Association at Chelsea, in May. Very cordial votes of thanks to the Provost and Town Council were proposed by Mr. Besant and Mr. Jeffrey, for the very kindly welcome which the members had received at their hands.

NATIONAL ROSE.

THERE was a good attendance at the Annual General Meeting of members of the National Rose Society on January 16, at the Caxton Hall, Victoria Street, Westminster, the room being comfortably filled. Mr. H. R. Darlington, the retiring President, was in the chair, and among other Rose enthusiasts present were Mr. Arthur Johnson, President elect, Miss Ellen Willmott, Mr. J. N. Hart, Mr. C. C. Williamson, Mr. H. Oppenheimer, Mr. J. R. Mattock, Mrs. C. A. Tisdall, Mr. Owen Murrell, Mr. Walter Easlea, Mr. J. S. Harvey Cant, Mr. S. A. R. Preston-Hillary, Hon. Treasurer, and Mr. Courtney Page, Hon. Secretary.

The report of the Council, which was adopted unanimously, records a most gratifying state of affairs. During the year 1928, 1,752 new members joined the Society, making a total of over 15,500. Five exhibitions were held, and the report mentions an appreciable advance in the quality of the blooms set out at these shows, as well as increased attendances. The Rose Conference also receives due attention in the report. The Society's trial of new Roses appears to be going ahead well, for over 2,000 plants have been received from raisers. The Council fully appreciates the importance of ensuring, so far as is humanly possible, that no buds of any of the varieties on trial shall be taken away and, with this end in view, has made a rule that members only shall be allowed to visit the trials.

Several matters of interest were discussed. Mr. Harvey, Guildford, mentioned the difficulty affiliated Societies experienced in obtaining competent judges of Roses for their shows, and suggested that the Council might well consider the possibility of standardising the judging—hold examinations of potential judges, and grant certificates to those who successfully pass the test. The President said he was sure the Council, which has devoted considerable attention to the matter, would give most careful consideration to the suggestions, but he pointed out the obvious difficulties which would attend any effort to meet the speaker's wishes. Mr. Herbert Cowley referred to the Gold Medal awards of the Society, and his contention that there was a certain amount of dissatisfaction concerning the awards evidently appealed to many present. Mr. Cowley suggested that now the Society was conducting trials of new Roses no variety should be awarded the Gold Medal until after trial. In reply, Mr. Darlington stated that he believed the awards to varieties at the trials would be quite distinct from any now given. The present award of the Gold Medal has a well-known character. It is given to Roses as staged, and he felt that it must be so in order to give some encouragement to raisers. The raising of new Roses is not a mechanical affair. There are a thousand and one disappointments to be met, and if the suggestion that no award should be given until the variety has been grown at the trials were adopted, too long a time would elapse. Mr. Darlington, continuing, stated that the award of the Gold Medal proved that, on one occasion at least, the Rose shown was capable of great things and this, in his opinion, is all that can be hoped for.

The financial summary, which was presented by the Hon. Treasurer, met with unstinted approval, as well it might. Although, as we remember happened with another special flower society during the year under review, a provincial Society, which invited the N.R.S. to hold a show in conjunction with it, had not met its obligations promptly enough for the donation to be included in the current accounts, the receipts were over £500 in excess of the previous year's. The Hon Treasurer made interesting, and not too laboured, comparisons between the position of the Society to-day and in 1914, and incidently paid a well-deserved tribute to the work of the Hon. Secretary, to whom, he insisted, the credit of the Society's splendid financial and numerical position was entirely due. With an increased membership it was a natural corollary that the expenditure should increase, so that such items as printing, stationery and postages were greater than before. Mr. Preston-Hillary expressed the definite opinion that the expenditure on the trials was well incurred and that by improving the cultivation of the Rose it would greatly improve the membership of the Society. Mr. Arthur Johnson expressed considerable surprise at the economy of the Society's working expenses which were, he said, astonishingly low and compared most favourably with those of any business concern in the city or elsewhere.

The proposed alteration of Rule 20 was a very minor affair and, as it tends to improving the amenities of the Society's working, was adopted immediately.

There were forty candidates for the thirty-six seats on the Council, and when the result of the voting was declared, it was found that Mr. F. M. Elgood, Mr. E. C. Green and Dr. R. C. Turnbull of the old Council were not re-elected, and that the new members were Mr. H. G. Crawley, Mr. A. Dickson, junr., Mr. A. T. Goodwin, Mr. Samuel McGredy, Mr. E. H. Plesance and Mr. W. D. Prior. After the customary votes of thanks the members partook of tea and were entertained with music.

Obituary.

William Curtis.—Four brothers, natives of Barnstaple, Devon, and all engaged in horticultural pursuits, have now passed away. The death of Charles, the youngest, an old Veitchian collector and, later, Superintendent of the Penang Botanic Gardens, was recorded in these pages last autumn; John, James and William resided in Wimbledon for many years and were gardeners of repute about twenty-five or more years ago. William Curtis moved to Worcester Park after the breaking up of the Mount Ararat estate, and with his younger sons commenced business as florist, and nurseryman. The war, and the death of the youngest son in France, were great misfortunes from which he never seemed to recover, although his general health was good until on January 10 he fell and dislocated his thigh; from this accident and the attendant shock he died a week later. Three sons and two daughters survive him, the eldest son being the Managing Editor of this journal.

Robert Andrew Duthie.—With deep regret, I record the death of Mr. Robert Andrew Duthie, aged sixty-five, at the Viceregal Gardens, Phoenix Park, Dublin, after a brief illness. He was laid to rest on the 16th inst., in Castleknoch Churchyard, Co. Dublin, many friends attending to pay the last token of respect, emphasised by a wealth of floral tributes. Mr. Duthie was a keen and skilful Scotch gardener long located in Ireland, filling in later years the important post of head of the Chief Secretary's gardens, from which he was transferred to the Viceregal charge some years since, and here Mr. Duthie did much to restore the prestige of these gardens once famed for fruit-growing generally, and Grapes in particular. His ability in the latter direction was pleasingly recognised by Mr. T. M. Healy, K.C., when invited to cut the first bunch of Grapes from vines planted fourteen months previously, by having a silver cup engraved: "Presented to Mr. Robert Duthie by T. M. Healy, K.C., First Governor-General of the Irish Free State," etc., etc. *K., Dublin.*

TRADE NOTE.

IT is highly satisfactory to be informed by Messrs. Rayner and Co., the well-known London Patent Agents, that last year will hold the record for patents, which reached the high total of 38,953, against the previous record of 36,680 in the year 1920. This is a matter of sincere congratulation, showing clear signs of our industrial progress, which should augur well for better trade for 1929. The Wireless world and the transmission of both sound and vision, as represented by the gramophone and the films, are responsible for a large portion of the increase; but the records show a general improvement in all trades, including those relating to the universal subject of the garden. Many people would probably consider that there was an important field for invention when the work of nature is so closely allied to the home. On consideration, they will see that the numerous tools employed in the garden form an important industry, and also the chemical side as to manures and fertilisers must be fully recognised; and here there are great opportunities for amateurs who love their gardens to make improvements to save labour and improve the products, and the records show that advantage has been taken in this respect, and indicate a revival of interest in inventions and patents associated with the garden.

ANSWERS TO CORRESPONDENTS.

APPLE TREES CANKERED.—*W. W.* The Apple shoots are suffering from a severe bud infection of the canker fungus. Remedial measures include: (1) The removal and destruction of badly cankered shoots and the wounds covered immediately with white lead paint; (2) keeping in check attacks of woolly aphis, which is often a precursor of canker, the fungus spores entering through wounds made by the insects; (3) annual spraying in early spring before the buds open, with lime-sulphur solution, using one gallon of lime-sulphur in nine gallons of water, and (4) drainage of badly drained and heavy land—badly-drained soils encourage the spread of the disease and cause the trees to become less resistant to attack.

DIMENSIONS OF ASSOCIATION FOOTBALL GROUND.—*Regular Reader.*—The measurements of an association football ground are as follows: Length 100 to 130 yards, width 50 to 100 yards (120 yards by 90 yards is usual); goal posts eight yards apart, with the cross-bar eight feet from the ground; goal area, six yards from goal line, 20 yards across; penalty area, 18 yards from goal line, 44 yards across; penalty kick mark, opposite centre of goal, 12 yards from goal line; kick-off circle, centre of ground, radius 10 yards. The corners should be marked with a flag on a staff not less than five feet high, while it is usual to mark the area from which the corner kick may be taken with an arc three feet from the flag post.

HEAD GARDENER AND COTTAGE.—*Civis.* It would appear that you were engaged on terms including the use of the cottage for yourself and your family, and that your wife was subsequently taken into the employer's service as housekeeper. So long as she remains in such employment the employer can require her to reside in his house, but on such employment being determined she would be entitled to return to the cottage and live with you, and the employer could not refuse to allow her to do so while you remain in his service on the terms originally arranged.

COLOURED SUPPLEMENT PLATE.

Venidium fastuosum.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39·7°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, January 30, 10 a.m. Bar. 30·2. Temp. 48°. Weather, Wet.

The Photosynthetic Activities of Green Plants.

As everyone knows, the green plant carries out with monotonous and effortless ease its daily task of supplying the world with sugars and other substances without which life on this planet would cease. The manufacturing activity of the green plant sustains the world. Although many have tried to discover the secret possessed by the green plant, none, so far, has been successful. Needless to say, however, the modern chemist, who has performed so many wonders in the way of synthesis, is not going to submit for ever to the reproach that " the veriest weed beside the brook " is his technical superior. Indeed, the chemist has already made some progress in his attempt to discover the processes whereby the green plant monopolises the trade of universal provider of the food. It is, of course, well known that the raw materials from which sugars are made by the green plant are carbon dioxide and water, and that the manufacture goes on only when the sun shines—hence the term photosynthesis—and it is also known that the synthesis occurs only in the living cells which contain chlorophyll — the green colouring matter of plants. The efficiency of the green plant in utilising radiant energy for this process is also disconcerting to the chemist, for the amount of energy contained in the light absorbed by the green plant is not enough for the photosynthetic work which the plant indubitably does. The green plant ought to use other light, for example, ultra-violet, which would give it all the energy necessary for photosynthesis; but the fact remains that it gets on very nicely and produces vast quantities of sugar, even when ultra-violet light is absent, provided, of course, that the plant receives ordinary sunlight. Professor E. C. C. Baly and his colleagues at Liverpool University have been for some years engaged in the task of surprising the photosynthetic secret which the green plant holds, and it now looks as though they are on the verge of success.* They have shown, for example, that when a stream of carbon dioxide passes through water irradiated by light from a quartz mercury lamp, carbohydrates (*e.g.*, sugars) are produced, which disappear quickly when the light is shut off; in other words, the reaction :—

$$\begin{array}{cc} \text{water} & \text{sugar} \\ + & + \\ \text{carbon dioxide} & \text{oxygen} \end{array}$$

is a reversible one. Professor Baly's next problem was how to make this reaction keep on going one way, namely, in the direction of the production of sugar. This he succeeded in doing to a limited extent by embodying a substance (ferrous bicarbonate) which can absorb oxygen. When the experiment was performed in the presence of this substance, the solution which remained was proved to contain sugar. Now, in the green plant one condition for the photosynthesis of sugar is that the granular chloroplasts which contain the green pigment are so minute and so numerous as to provide a vast extent of surface. It has been estimated, for example, that the area of the surface of the chlorophyll grains of a single leaf of a green plant is equal to that of a tennis court. Acting on this and other information, Professor Baly and his colleagues repeated their experiments, but used a finely divided material, aluminium powder, suspended in the water through which carbon dioxide irradiated by ultra-violet light was passed. By this method, a larger amount of carbohydrate was obtained. The experiment, moreover, led to the conclusion that the photosynthetic reaction takes place at the surface of the chlorophyll grains, which conclusion had already been reached by plant physiologists. What now, it may be asked, will happen, when, instead of ultra-violet light, ordinary visible light is used, and if at the same time the solution is coloured green? Experiment supplies the answer. The illuminated water was coloured by a suspension of nickel carbonate, a stream of carbon dioxide was passed through it and yielded carbohydrate. Greenness, however, seems not to be necessary; a pink material, *e.g.*, cobalt carbonate, will do as well; so that Falstaff, had evolution so willed it, might have babbled not of green but of pink fields. The conclusions to which these experiments point are that the energy for the photosynthetic process is supplied in part only by sunlight, the rest being surface energy provided by the surface of the innumerable and minute chloroplasts. According to Professor Baly, the amount of carbohydrate synthesised by a given area of leaf is about as much as that produced artificially in vessels in the laboratory. That being the case, we may look forward presently to experiments which lead to the production of sugar on a considerable scale, and perhaps beyond that time to a remote future when the green plant will cease to count in the feeding of the world; if so, then horticulture, which is surely an older science, will live when its younger sister agriculture is no more.

Our Coloured Supplement Plate.—Venidium fastuosum is the subject of the Coloured Supplement Plate presented with the present issue; reference is made to this species by Mr. T. Hay, on p. 76.

The President of the Royal Horticultural Society.—The nomination of a successor to Lord Lambourne, as President of the Royal Horticultural Society, is a matter that has greatly exercised the minds of the members of Council for several weeks past. The subject has also been discussed freely by those Fellows who regularly attend the Committee meetings and exhibitions at Vincent Square, and among them there is a hope that some one of outstanding personality will be chosen; one who has strong horticultural sympathies and inclinations, who is *persona grata* in what is known as " high Society," and who is able and willing to give ample time to the guidance of the affairs of this great Society. His position and qualities must be above the average if the new President is to receive the whole-hearted support of that considerable body of members who now take a keen and critical interest in the work of the Society. All Fellows will appreciate the difficulties the Council must surmount in their efforts to place before the Fellows a nomination that will meet with general approval—a figurehead President will not be approved as a successor in that long line of notable men who have filled the Presidential chair—Lord Lambourne, Sir Trevor Lawrence, Lord Aberdare, the Duke of Devonshire, the Prince Consort, Thomas Andrew Knight and the Earl of Dartmouth.

—— Since the foregoing was written, and just as we were going to press, we received the following note from Mr. F. R. Durham, Secretary of the Royal Horticultural Society :—" I am directed to inform you that the Council of the Royal Horticultural Society, at their meeting on January 29, elected Mr. G. W. E. Loder President of the Royal Horticultural Society."

A Statue for Kew.—The Royal Academy of Arts, through the Leighton Fund, has presented to Kew the statue of " A Sower," by the late Sir Hamo Thornycroft, R.A. It was shown at the International Exhibition of Garden Design organised by the Royal Horticultural Society last October. The statue was originally made of plaster, but the Royal Academy has had it cast in bronze. It was placed in position on January 23, on a pedestal, also presented by the Royal Academy, and designed by Sir Edwin Lutyens, R.A., and Mr. A. Drury, R.A. The site selected is at the end of the Broad Walk, near Kew Palace, and not far from the main gate.

A Subterranean Orchid.—Very great interest was shown by the Fellows of the Linnean Society in a remarkable West Australian subterranean Orchid exhibited by Dr. A. B. Rendle. This Orchid has recently been described by Dr. R. S. Rogers in a communication to the Royal Society of Western Australia. The first specimen was turned up by the plough of an observant farmer in Western Australia, and sent to the West Australia Agricultural Department; a notice in the press produced specimens from two other localities. Dr. Rogers sent photographs and a short account of the plant, which he felt sure he would consent to being brought before the Linnean Society. The plant consists of an underground rootless rhizome, which is " in symbiotic relationship with a fungus which closely invests the decayed roots of

---

* " Photosynthesis," by Professor E. C. C. Baly. *Proceedings of the Royal Institute of Great Britain.* Vol. XXVIII, No. 122, Oct. 1928

Melaleuca uncinata, R.Br." It lives about a foot below the surface of the ground. The figures showed short rhizomes with a terminal bud and slender lateral branches covered with scale-leaves. The flowers are borne in a dense head surrounded by an involucre of bracts terminating a slender scape, which grows from the rhizome apparently towards the surface of the soil. The inflorescence, which suggests the capitulum of a Composite, reaches about three inches across. The relatively large bracts surround numerous small flowers. The plant " when fresh is colourless," but " the capitulum acquires purplish-coloured tints on exposure to light." Dr. Rogers wrote :—" The affinities of the plant are, of course, with the Gastrodinae, especially as regards its vegetative parts, but I feel that its inflorescence and certain other characters are too extraordinary to include it in the sub-tribe without unduly extending its limits. I have therefore thought it better to accommodate it in a new sub-tribe, which should be placed next to Gastrodinae." Mr. H. N. Ridley compared this Orchid to Gastrodia malayana, and suggested that the plant must at times come to the surface to be fertilised and to disperse its seeds, and that the coloration seemed to confirm this. Lt.-Col. J. H. Tull Walsh considered that a flower which only just emerged from the ground might easily have escaped observation. Mr. J. Ramsbottom pointed out the similarity of the subterranean Orchid to the saprophytic prothalli of Lycopodium; and suggested that subterranean plants are invariably associated with fungi, and that probably all plant saprophytes were symbiotic. Commenting on the similarities between the Australian Orchid and the Japanese Gastrodia elata, of which lantern slides had been shown, he stated that the fungus concerned in the second, Armillaria mellea, was well-known for its destructive parasitism, being the most dangerous parasite in European forests. When it attacked the Potato tuber it reduced it to a mash in a day or two, but when it attacked a similar-looking Gastrodia tuber, an association was set up without which the Orchid was unable to flower. Dr. G. P. Bidder pointed out that in ordinary English farming the plough would not uncover a plant the top of which was a foot below the surface.

Royal Gardeners' Orphan Fund.—Mr. Samuel Wallrock, The Manor House, Stanmore, Middlesex, has promised to preside at the next Annual Festival Dinner of the Royal Gardeners' Orphan Fund, which will be held at the Savoy Hotel, Strand, London, on Wednesday, May 15, next.

Darnaway Forest.—Members of the Royal Arboricultural Society of England, who included in their itinerary a visit to the great Darnaway Forest during their excursion to Scotland last summer, will be interested to learn that the Earl of Moray, proprietor of Darnaway, has written a volume for private circulation, which gives a fine account of the history of the forest, one of the finest in the north of Scotland, or, indeed, in the British Isles.

Appointment at Vienna University.—Professor Dr. Gustav Klein, formerly first Assistant at the Institute of Plant Physiology of the Vienna University, has been appointed Head of the Institute in succession to Hofrat Molisch. Professor Klein, who is a native of Vienna, is only thirty-six years of age, but has already made a name as a chemist and physiologist and by his researches into the effects of fertilisers and of artificial light on the growth of plants.

Aberdeen's New Glasshouses.—The new glasshouses in the Duthie Public Park, Aberdeen, which have been under construction during the past few months, are now reaching completion. The removal of the contents of the old houses to the new quarters is now engaging the attention of the park staff. Erected at a cost of several thousand pounds, these new and up-to-date houses should, needless to say, prove a great help and convenience to Mr. W. B. Clark and his staff in the administration of Aberdeen's horticultural affairs. Mr. W. B. Clark has, by-the-way, been appointed a Vice-President of the Scottish Branch of the Parks and Botanic Gardens Superintendents' Association; the appointment is a popular one. The Scottish membership is twenty-seven, comprising the élite of Scottish public parks superintendents.

Mr. Henry H. Cook.—After serving his apprenticeship under his father, who was then gardener to Sir Francis Wise Low at Kilshane, Tipperary, Mr. H. H. Cook went to Dalkeith as journeyman under the late Mr. J. Whytock, and later became indoor foreman and decorator at Alloa House, Alloa, the residence of the Countess of Mar and Kellie. The experience thus gained fitted him for the post of general foreman at St. Anne's, Dublin, the residence of Lord Ardilaun, under Mr. Andrew Campbell. Here he remained for nearly two years before becoming gardener to Lt.-Col. Sir Hutcheson Poe, and carried out the reconstruction of the gardens and pleasure grounds in accordance with the designs of Sir Edward Lutyens. Altogether, he filled this post for five-and-a-half years. Mr. Cook conceived the idea of entering public service, and to that end secured an appointment under Mr. McHattie, at Edinburgh, where he had charge of the famous Princes Street Gardens. However, a year later, he became gardener at Drummond Castle, where he remained until the effects of the war necessitated a reduction of staff. In 1919, Mr. Cook was appointed lecturer and practical instructor in horticulture at the Reading University, a position he still holds. Mr. Cook is now contributing regular notes in our Week's Work columns, but he has written much on horticultural subjects for various journals. He has taken considerable interest in the flourishing Reading Gardeners' Mutual Improvement Association, and was its Chairman in 1922. He is one of several brothers who have each made a name in horticulture, *i.e.*, Mr. C. H. Cook, at Windsor, and Mr. T. H. Cook, at Sandringham.

MR. HENRY H. COOK.

January's Weather.—It seems that the month just ended has been the most persistently cold January for thirty-four years. During other winters lower temperatures have been recorded, but throughout January the temperature has been consistently low over practically the whole of the country. In some districts of the midlands and the east of England the thermometer, at the time of going to press, had not risen above 43°, while in the Metropolitan area the highest readings were 46° at Greenwich, and 45° at Kew and Hampstead. *The Observer* of last Sunday gave some interesting comparisons, and stated that observations over the last eighty-eight years at the Royal Observatory show that the only other January months during that period which had very low temperatures were those of 1842, with a maximum of 44°; and of 1881, with 43°. In other years of the period the January readings always showed over 50°, a temperature which was exceeded sixteen times in January of 1916, and fifteen times in 1917. Older records show that in 1814, when the river Thames was frozen completely from London Bridge to Blackfriars, the January mean temperature was 27°; the maximum temperature during the first twenty-six days was 36°, although three days later it was comparatively high at 41°. Besides the persistent cold, the month now ended has been noteworthy for its lack of sunshine, high barometric readings, exceptionally small rainfall and the prevalence of winds from between the north and the east.

Potato Drying by Sugar Beet Plant.—The Peterborough Sugar Beet Factory recently carried out an experiment of drying sliced Potatos as food for farm stock. It had been suggested before that the Sugar Beet factories might well consider the utilisation of their drying machinery during the time that it is not at work on Sugar Beet, for the treatment of other crops. The experiment appears to have been a success, although it is too early yet to say much about it, except that the best results appear to have been obtained from drying a mixture of Sugar Beet pulp and Potatos. Here, at any rate, is a promising additional cattle foodstuff in years of Potato plenty.

Bradgate Park acquired for the Nation.—We learn that Bradgate Park, the historic home of Lady Jane Grey, situated five miles from Leicester and covering an area of eight-hundred-and-twenty-eight acres, has been acquired for the use of the public for ever, by the County and City of Leicester, through the generosity of Mr. Charles Bennion, of Thurnby Grange, Leicester.

A Press Guide for Auctioneers.—We have received a copy of *The Auctioneers' Press Guide* (5, Clement's Inn, London, W.C.2), which is published this year for the fifth time. This useful little publication has found its way into the offices of most country estate agents and bailiffs, and is well-established in favour with those who have learnt to depend upon it for information on rates of advertisements. Where enquiries by post mean a delay of at least two days and the expenditure of much time and many postage stamps, its modest price of 2s. seems small indeed.

Blackleg of Potatos.—In a communication issued by the Department of Agriculture for Scotland, it is stated that the Potato disease known as " Blackleg," has been unusually prevalent during the past season. Symptoms of the disease are the blackening and rotting of the stems at the base, with a consequent wilting of the foliage, and a serious loss of crop. The disease may be reproduced by planting tubers from diseased plants, but its development depends on the character of the soil and season, being most pronounced under wet conditions. An important factor, however, in the increased prevalence of the disease seems to be the use of cut seed sets, and it is strongly recommended that sets should not be cut for planting on farms where it is known that the Blackleg is likely to occur.

German Nursery Employee's Long Service.—Otto Frenzel, a responsible employee of the firm of F. C. Heinemann, nurserymen in Erfurt, has just celebrated his sixtieth year in the service of the firm, which he entered in 1869, at the age of thirteen. He has known three generations of his employers, and enjoys, for one of his advanced age, very good health.

Sweet Pea Annual.—Ever since its earliest years, the National Sweet Pea Society's annual publication, *The Sweet Pea Annual*, has been looked forward to with great interest by members. As in the case of so many other Societies, the war period adversely affected membership, and the Committee had to be content to do what it could rather than what it would. Now, however, the Society is enjoying better times, and a membership of about seven hundred, in addition to about one-hundred-and-thirty societies affiliated to it. Moreover, the accounts for 1928 show a balance of £152, and the balance sheet shows a surplus of assets over liabilities to the amount of £427. Considering these matters, and remembering the immense popularity of the Sweet Pea, it would appear that the time has come when the Sweet Pea Society should produce an *Annual* more in keeping with its national standing and the fact that it has the second largest membership among our floricultural societies. The present issue, with its frontispiece portrait of Mr. Harold Beale—the President—is interesting, but suggests that the General Committee has imposed somewhat severe restrictions upon the Editor and the Publications Committee. Mr. Burt's account of the conduct of the Society's Novelty Trial at Coggeshall is unusually useful, and we believe nothing of the kind has been published hitherto. Mr. T. A. Weston, who now resides in the U.S.A., retains his old-time enthusiasm for Sweet Peas, and writes entertainingly about the new multi-flowered strain, of which an illustrated account appeared in *The Gardeners' Chronicle* of August 8, 1928, under the title of "Multi-peduncled Sweet Peas." It has been acknowledged that the essay competition of 1928 was not a success; nevertheless, the successful competitors put forward several interesting suggestions for the further popularity of the Sweet Pea. The report of the useful work of the Floral Committee, the annual report and accounts, and the lists of members and affiliated societies are included, and occupy considerable space. Mr. Burt's audit of the exhibitions in 1928 suggests that efforts to reduce the number of Sweet Pea varieties have not been very effectual, seeing that no fewer than one-hundred-and-twenty varieties were exhibited at Bournemouth in July, and ninety-three at Southport, in August. Fourteen illustrations adorn the text. To non-members, the price of the Sweet Pea Annual is 3s., post free, and copies may be obtained from the Secretary, Mr. A. C. Bartlett, 19, Bedford Chambers, Covent Garden, London, W.C.2.

Legacies to Gardeners.—The late Mr. C. C. Cowlin, J.P., of St. George's Hill, Easton-in-Gordano, Somerset, who died on December 1, 1928, left £50 to his gardener, Mr. W. Pearce, if still in his employ.—The late Mr. Arthur Henry Foster, of Green Lane, Moseley, Birmingham, who died on November 14, 1928, left £1,000 and an annuity of £52 to his head gardener, Mr. Thomas Perry, for long and faithful service.

Scottish Potato Trials.—The Department of Agriculture for Scotland announces that it is now making arrangements for the continuance, during the coming season, of the trials conducted by it for the testing of new varieties of Potatos for immunity from Wart disease. Growers and merchants who have stocks of new varieties which they desire to have tested should forward samples by post to the Director of the Seed-testing and Plant Registration Station, East Craigs, Corstorphine, Edinburgh, to arrive not later than March 18. A note of the name and reference number should be enclosed with each sample. Subsidiary to the main trials, facilities are provided by the department for testing single tubers of seedlings. This test, which is a one-season test only, is designed to enable Potato breeders to discard, at an early stage, varieties which are susceptible to Wart disease. The test is limited to seedlings in the first or second year of their existence from true seed.

Appointments for the Ensuing Week.—MONDAY, FEBRUARY 4: East Anglian Institute of Agriculture lecture; National Chrysanthemum Society's annual meeting. TUESDAY, FEBRUARY 5: Royal Caledonian Horticultural Society's meeting. WEDNESDAY, FEBRUARY 6: National Carnation and Picotee Society's meeting; Wimbledon and District Gardeners' Mutual Improvement Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. THURSDAY, FEBRUARY 7: Bideford and District Horticultural Society's meeting. FRIDAY, FEBRUARY 8: Royal Horticultural and Arboricultural Society of Ireland's meeting. SATURDAY, FEBRUARY 9: Leeds Paxton Society's meeting and lecture.

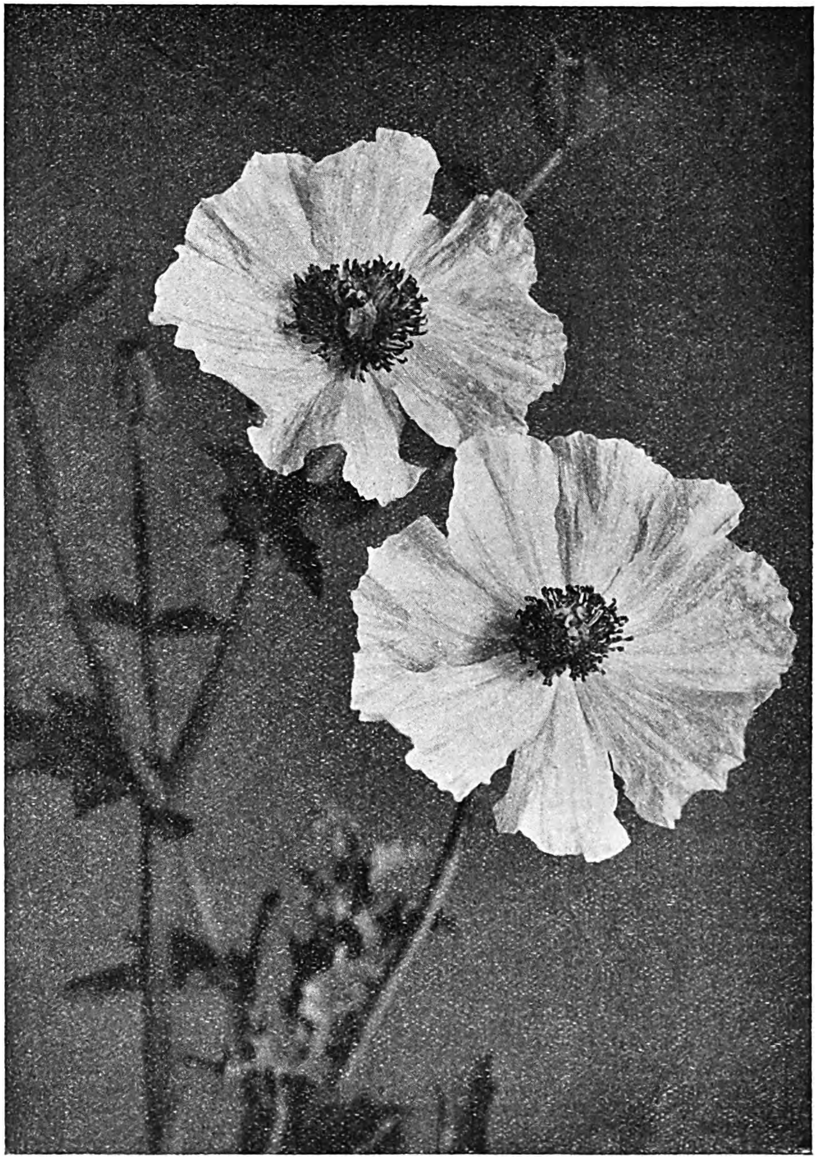

FIG. 36.—ARGEMONE GRANDIFLORA.
(see p. 77.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Horticultural Society's Garden, Turnham Green.*—In the American garden, the Sikkim Rhododendrons, Edgeworthi, Dalhousie and glaucum, have all been killed, while ciliatum and the large variety of it called alpinum, have stood well, not a leaf being browned, and they are at present well set with flower-buds. The long, hard leaves of the Pampas Grass have lost their colour, and look bleached by the frost. The Californian evergreen Cherry is scarcely at all touched; and the same may be said of Ilex latifolia, which has stood well. The Yucca-like Dracaena indivisa has lost its top, the latter, so far as the leaves were young and tender, having melted, as it were, away by the frost. Quercus Cooki, Garrya macrophylla, and the Chinese Privet, have all had their leaves browned, while the Chusan Palm has escaped uninjured. The beautiful evergreen Californian Gale (Myrica californica) has proved itself to be perfectly hardy, not a leaf on it being browned; Escallonia macrantha has been a good deal injured. On the conservatory wall, Acacia melanoxylon has been killed nearly down to the ground, various Ceanothuses have had their leaves browned, and some other things have been more or less hurt; but upon the whole, less mischief has been done here than might have been expected. Jasminum nudiflorum is now in full blossom on this wall, its bright yellow flowers having a very cheerful effect. The different kinds of Chimonanthus are also in flower at present, and are great favourites, on account of their delicious fragrance. In the large conservatory, Acacia Riceana, quite a tree in size, is now coming beautifully into bloom, as are also the Camellias, more especially the large-flowered sort called elegans, which is just beginning to open multitudes of showy blossoms. The Lucilia gratissima has been flowering finely, but its beauty is now nearly over. An early pink Chinese Azalea is at present in full bloom and that without any forcing. *Gard. Chron., February* 4, 1854.

Publications Received.—*The Trees of New Zealand*, by L. Cockayne, Ph.D., F.R.S., and E. Phillips Turner, F.R.G.S. The New Zealand State Forest Service, Wellington; price 4s.—*The Plant Life of the Balkan Peninsula*, a Phytogeographical Study, by W. B. Turrill, M.Sc. The Clarendon Press, Oxford; price 30s.—*Smith's Advertising Handbook.* Smith's Advertising Agency, Ltd., London; price £1 1s. 0d.—*Annalen des Naturhistorischen Museums in Wien*, by Dr. Karl Keissler, 1928.—*Les Plantes Alimentaires chez tous les Peuples*, Vol. II, Phanérogames Fruitières, by D. Bois, Paris.—*The British Journal Photographic Almanac*, 1929, ed. by G. E. Brown. Messrs. Henry Greenwood and Co., Ltd., 24, Wellington Street, W.C.2; price 2s. (paper), 3s. (cloth).—*Die Praxis des Baumschulbetriebes*, by Paul Rache. Berlin, 1929; price Rm. 25.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Platyclinis glumacea.—Plants of this easily-grown and fragrant Orchid, which have been resting in the cool house, are now commencing to grow, and the flower spikes will soon be seen in the young growths. The plants should be removed to a warmer temperature and will require more water at the roots as the growths and flower spikes develop. As the flowers expand they will keep perfect for a longer period in cooler and drier conditions, and so soon as they have flowered, they should be removed and any necessary repotting done. Use well-drained receptacles for this purpose and a compost consisting of three-parts Osmunda and A.1. fibres, one part Sphagnum-moss, and a few crushed crocks. The plants thrive well at the warm end of the intermediate house, and should be sprayed lightly, especially on the undersides of the leaves, during warm weather; this should keep red spider in check. Water should be afforded sparingly after root disturbance, until the new roots are well-established in the fresh compost, when copious supplies will be needed each time the compost becomes fairly dry, until growth is complete, when drier and cooler conditions may be afforded to give the plants a partial rest. The summer-flowering species, P. filiformis and P. latifolia, and the autumn-flowering P. Cobbiana, are still resting under cool conditions, and only require sufficient water to keep the plants in a normal state; when growth commences they should be given similar cultural treatment as advised for P. glumacea.

Sophronitis grandiflora.—Where a quantity of these dwarf-growing, brilliantly-coloured Orchids are grown, a succession of scarlet flowers may be had for several months. Some of the earliest plants are now passing out of flower and these will require attention to assist the partially developed bulbs to reach maturity, growth being slow at this season. They require all the light available, and may be grown suspended in a house with an intermediate temperature, removing them to a cool house when growth is complete. While they are growing, care is needed to prevent moisture collecting in the young growths, as decay quickly sets in. The roots should not be allowed to remain dry for long periods at any stage, as the small bulbs soon shrivel. Any fresh rooting material should be afforded as new roots develop from the young pseudo-bulbs.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Pot Fruit Trees.—Peaches and Nectarines are, perhaps, grown most extensively in pots, as with a few of the earliest varieties of these trees started in December, one may defer closing the first Peach house until the turn of the year. All the stone fruits do well in pots, when judiciously managed, under glass. Choice Pears and the finest varieties of Plums and Cherries may be induced to yield ripe fruits long before fruits of the same varieties may be obtained from plants against walls. The chief requirements for their successful culture are a light, well-ventilated house, with at least one four-inch pipe running around the interior, and healthy trees, thoroughly established before they are taken in for the mildest forcing. In the selection of trees, those with stout, but not over strong, short-jointed shoots, with well-balanced heads, should be chosen, in pots nine to twelve inches in diameter. The pyramid form is most in favour, as it exposes the greatest external area to the sun and light, an important matter when rich colouring and early maturing are desired. Much depends, however, on the height and aspect of the structure. None but the very best varieties should be grown under glass; good sorts may be duplicated to any extent until the allotted space is filled up. Pears, Plums, Apples and Cherries have been most successfully forced for numbers of years, and few fruit trees give better returns or more pleasure when in flower and fruit. Success in forcing them depends on the avoidance of subjecting them to a high temperature or close atmosphere when the weather is fine; the temperature may fall below 40° when the weather conditions are very severe, without harm to the trees. All that is needed is a fresh, warm, airy atmosphere, the covering of glass alone protects their flowers from frost, while fresh air admitted freely ensures crops of fruits superior in every way to those grown outside. Pears under glass produce fruits of enormous size; gardeners in the north of England and Scotland plant and train cordon Pear trees under glass and obtain exceptionally fine fruits by feeding them liberally and ventilating the houses freely. The above remarks also apply to the best varieties of Apples. Cherries are excellent for growing under glass, but they should not be forced too quickly into growth; it is better to wait until more sun-heat is available. When the buds begin to swell, a mean temperature of from 40° to 45° at night and 50° to 55° by day should suit them; admit fresh air and maintain atmospheric moisture in proportion to external conditions. Green and black aphis generally attack Cherries no matter how carefully the trees may have been cleaned, and two or three mild fumigations should always precede the opening of the first flowers. When the trees come into flower, a fairly dry atmosphere, with plenty of fresh air, and a temperature of 65° secured with the aid of the sun, should ensure a good set of fruits.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Liliums.—There is no class of bulbous plants that gives more pleasure than that of Lilies. Many of the hardier sorts are excellent for grouping in the herbaceous border, where they may be left undisturbed for years if given a annual top-dressing of well-decayed manure and leaf-soil. Where soils are of a medium texture and naturally well-drained, the special requirements of the different kinds may be afforded easily when planting. Light soils will be benefited by an addition of moderately heavy loam, and to heavy soils the admixture of sharp sand or grit and old potting soil will be an advantage. Manure should never be dug in just before planting, but Liliums respond freely to annual top-dressings after they are established. They prefer partial shade, but not a position which is densely shaded by trees. A position where they are sheltered from the north and east by shrubs, open, yet screened from the heat of the mid-day sun, will suit them admirably. Such positions may usually be found at the edges of beds or borders containing Rhododendrons or other shrubs. As these beds have usually been prepared well for the shrubs, they form ideal positions for many of the stronger-growing Liliums, for the foliage of the shrubs gives the necessary protection to the young, tender growths in spring and later shades the bases of their stems from the hot rays of the sun. Whatever the state of the soil, it will be found advisable, when planting, to place a few handfuls of sharp sand under and around the bulbs to preserve them from excessive moisture during the winter. Heavy importations of Lily bulbs take place annually, particularly of L. auratum, from Japan; these are now available, and the necessary stock of bulbs should be secured so soon as possible. As bulbs of Lilies are composed of fleshy scales which soon wither and dry up if left exposed for any length of time, it is necessary to secure and plant or pot them with as little delay as possible. When choosing bulbs for planting in the open, it is unwise to select the largest; medium or small-sized bulbs usually give the most satisfactory results. If the smallest bulbs are planted it is deemed advisable not to allow them to flower the first season; this ensures the building up of strong bulbs for the following season. Where it is intended to make use of Liliums as bedding subjects in the flower garden during the summer, the bulbs should be potted up so soon as received and stood in the open, covering the pots with Cocoanut fibre or half-decayed leaves. When rooted and started into growth they may be grown on under glass if required for an early display. A good many sorts are available at this date; others should have been planted during last autumn. Chief among those that may be procured now is Lilium auratum, good forms of which have flowers ten inches to twelve inches across. The variety platyphyllum is a robust grower and gives better results in many places than does the type. L. a. rubro-vittatum, which has a crimson band on the petals and dark green foliage, is also a strong grower. L. Henryi should be included in every herbaceous border of any size; it is a tall and vigorous grower, and when established, produces its orange-yellow flowers with the greatest freedom. L. speciosum Kraetzeri, L. s. Melpomene, L. s. rubrum and L. s. album may all be employed with advantage either in the shrubbery, the herbaceous border, or for summer bedding. The Tiger Lily needs no recommendation as a useful species, with orange-scarlet blooms, for providing a display in the late summer. The variety known as L. t. splendens is much finer than the common form, and should be grown in preference to it.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hatfield, Hertfordshire.

Cleansing Plant Houses.—The present time is the most favourable for the overhauling of plant houses. The structures should be thoroughly cleansed, and all the walls should receive a coating of lime. All plants, whether growing in pots or borders, should also be cleansed. Climbing plants should be pruned or thinned as their requirements demand, and the shoots tied neatly to the trellises; those growing in borders should receive a top-dressing of a mixture of loam, peat, leaf-mould, charcoal, and a good sprinkling of coarse sand.

Gloxinias.—A batch of Gloxinias may now be started into growth. Place the tubers in boxes containing fine leaf-mould and silver sand, in a light position and a warm, moist atmosphere. So soon as growth commences, the tubers may be potted into the pots in which they are to flower, using for this purpose, a compost of fibrous loam, peat, leaf-mould, crushed charcoal and coarse sand. If young plants are to be raised this season, seeds should be sown without delay in well-drained pots or seed-pans. The surface of the compost should be made perfectly level and firm by pressing it lightly, and the seeds may be just covered with fine, sandy soil, and watered with a very fine-rosed can. Shade the receptacles from bright sunshine and cover them with a piece of glass, tilted back about half-an-inch, until germination takes place. Never let the compost become dry, and when the seedlings appear, gradually expose them to the light and air, to prevent them becoming drawn or weak. So soon as they may be handled with safety, prick them off into shallow boxes, and when they have made sufficient growth, place them singly in small pots, moving them later before they become pot-bound into the receptacles in which they are to flower.

Begonias.—Begonia knowsleyana and Begonia kewensis are two very useful Begonias, as they flower freely during the winter months. They require to be grown in an intermediate house until the young plants become established in large sixty-sized pots, but during the summer months they may receive their final potting and be grown in frames, provided they are taken into a house having a temperature about 55° to 60° on the approach of cold weather. These two Begonias may be propagated freely from cuttings, but the propagator should be sure that the cuttings are free from rust and mite. Cleanliness is an important factor in the successful cultivation of Begonias.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Lecturer in Horticulture, Reading University.

Raspberries.—If we consider the conditions which prevail where this useful fruit is found in a wild state, we find that the soil is deep, rich, and plentifully supplied with moisture, but not water-logged. It is to be found in partial shade, but the finest flavoured fruits are obtained when the fruits are grown in full sun. Where the ground has been prepared by trenching and thoroughly enriched with organic manure, no time should now be lost in getting the young plants into their permanent positions. Raspberries may be raised easily from seeds, and the seedlings should bear fruits in the third or fourth year. The general method of increase, however, is from suckers, which are produced in abundance on most varieties. Those that arise at a distance of a foot to eighteen inches from the parent plant are generally provided with many more fibrous roots than are those which arise close to the canes. These young suckers should be lifted carefully and planted in their permanent quarters, to bear fruits the second summer. Raspberry canes should have some sort of support, and the system of planting should be arranged according to the form of support to be adopted. In every case the young canes should be cut down, almost to the ground level, immediately after planting. The simplest method is to plant them two feet apart in rows five to six feet from each other. The training, in this instance, consists in bending the canes over right and left, to form a series of arches, which will be found a simple and effective means of support. The second method is to plant them in groups of three, with a strong stake in the centre of each eighteen-inch triangle, to which the canes are produced. These groups should be four feet from centre to centre. The third method, and the one usually employed on commercial plantations, is that known as the espalier fence. This fence consists of strong, terminal posts, with lighter intermediate posts, five feet high, to which three galvanised wires are attached. The young canes are planted eighteen inches apart along this fence, and as the plants develop, the canes are secured to the wires, spacing them out fan-wise three inches apart. The pruning, for the summer-fruiting varieties, consists of cutting out the old canes after the fruits have been gathered, tying in the strongest of the young canes, and removing the weakest. With the autumn-fruiting sorts the pruning consists of cutting back all the growths of the previous season any time during the dormant period. The fruits of these are borne during September and October on the tips of the current season's growths. The types of soil suited to different varieties vary, so a trial is recommended before the extensive planting of any one variety is carried out. On the stiff, clay soil here, we find the varieties Lloyd George, Laxton's Prolific, Baumforth's Seedling and The Devon do best. The Hailsham-berry, Lloyd George, and November Abundance are a few of the best autumn-fruiting varieties.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunstar, Somerset.

Cucumbers.—If a sufficiently high temperature can be maintained to ensure rapid germination, Cucumber seeds may be sown now. They should be sown singly in small pots filled with good loam. Plunge the pots in a propagating frame with bottom-heat, and when the seedlings are about two inches high, remove them to a shelf near the glass, where they will receive plenty of light. Great care is necessary in watering them during these early stages, for they are very liable to damp off.

Leeks.—Where specimen Leeks are required for early use, or for show purposes, seeds may be sown now in boxes and germinated in heat, the seedlings being grown on under the same treatment as afforded Onions. The seedlings, when large enough, should be pricked off into boxes, which should have a layer of decayed manure placed in the bottom. Plenty of heat and moisture are two conditions necessary to secure good results.

Spinach.—The Spinach bed should now receive an application of soot, which should be dusted between the lines, and the surface of the soil should be stirred, when in suitable condition, with the Dutch hoe.

Seed-sowing.—As time advances, it is important, if large quantities of vegetable seeds are to be sown, to make preparations for this important work in advance. The frames, for instance, if available, should have the seed-beds prepared in them now, so that sowings of early crops may be made. Fresh horse manure should be placed at the bottom and made firm, and on this should be placed at least fifteen inches of soil, which, after being trodden moderately firm should be raked level, the surface being reduced to a fine tilth. Among the subjects which may be sown at the present time in these frames, in drills about nine inches apart, are Carrots, Turnips, Spinach, Lettuces and Radishes, while sowings may also be made of Brussels Sprouts, early Cabbage, Cauliflowers and Savoys, to secure plants for planting out early.

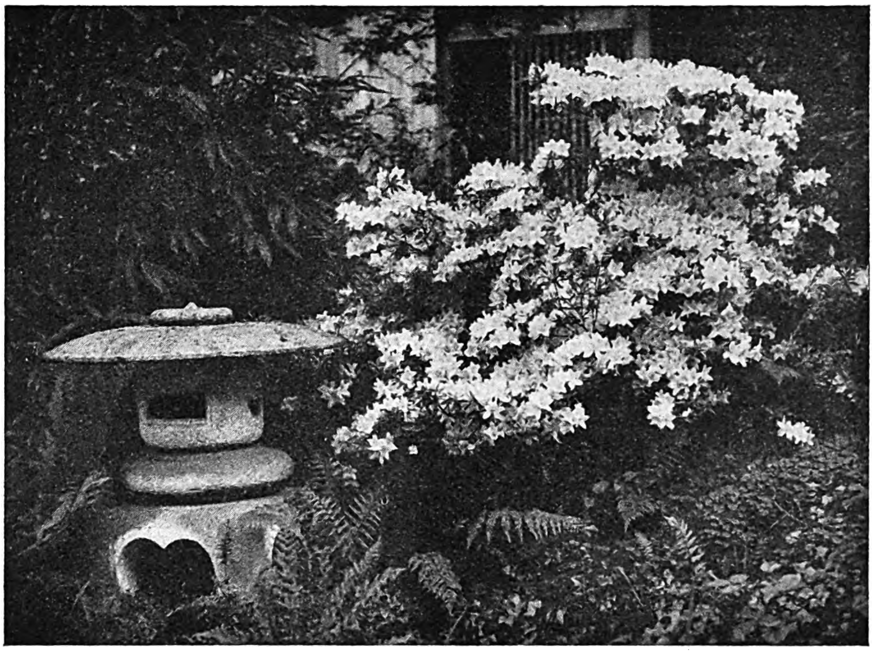

FIG. 37.—A JAPANESE AZALEA IN A HEIDELBERG GARDEN.
(see p. 78.)

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemount, Monkton, Ayrshire.

Early Vegetables.—Carrots of the Short Horn type, early Turnips, Radish and Lettuce, may now be sown in frames or pits in seed-beds above a fermenting material. If early Leeks are required, seeds of these may also be sown under glass, in case sowing out-of-doors is delayed owing to wet weather. Seeds of a good early variety of Peas should also be sown now either in pots or boxes. I prefer to sow them in long, trough-shaped boxes, wider at the bottom than at the top, with the bottom held in place by string; this can be removed easily, and the whole contents of the boxes planted without disturbance. The Pea seeds may be started in heat, but so soon as the seedlings appear, remove them to a cold frame and keep them close up to the glass. Where mice are likely to prove troublesome, take steps to keep them at bay, either by wetting the seeds in paraffin oil and rolling them in red lead.

Onions.—On the first favourable day, *i.e.*, when the soil is not sticky, stir the surface of the soil of the intended plot for Onions with a digging fork or cultivator to a depth of two or three inches; this may need to be done more than once before the required tilth is obtained, and is most important, not only for Onions, but for all fine-seeded vegetables to be sown in the open ground.

Jerusalem Artichokes and Shallots.—Both these subjects may be planted whenever the ground is in suitable condition. The sooner they are planted the better, but it is better to wait even for a month if the ground is in a sodden condition. Jerusalem Artichokes should not be grown in rich soil, and should be given plenty of room, about three feet between the rows being sufficient.

Cyclamens.—If these were sown in August or September, the seedlings should now be ready for placing into small pots or boxes. I prefer the latter for this first shift, as a more even condition of moisture can be maintained at the roots. The soil should consist of two parts loam, one part flaky leaf-mould and one part rough sand and lime rubble, passed through a half-inch-mesh sieve, the rough material being used for providing the drainage at the bottom of the boxes. Insert the small corms just level with the surface, and do not pack the soil firmly around them; place them in a house with a temperature of about 60°, spray frequently on bright days, and shade them only from very bright sunshine. Keep them growing steadily, avoiding any checks that may be occasioned by attacks by pests or lack of moisture.

Digging and Trenching.—Take advantage of every suitable opportunity to dig or trench all vacant ground, but nothing is to be gained by working on wet soil if it is of a heavy nature. Many soils are better dug in spring than in autumn; experience will show which is best in each instance. The quarters for winter Broccoli should not be dug or trenched, for if they are planted on loose, open land the growth is too soft to withstand the winter; they do perfectly well on the hardest ground if a little loose soil, such as old potting compost, is put into the holes made for the reception of the plants. Brussels Sprouts also do well under this treatment, and do not become so tall as when planted on freshly dug ground; surface cultivation with the Dutch hoe after planting is all that is necessary until earthing up takes place, when the beds may be dug lightly with a fork to enable this operation to be performed satisfactorily.

FLOWER GARDEN.

ANNUAL FLOWERS.

During the past few years, our great seed houses have done much to stimulate interest in annual flowers, and their superb examples of good cultivation which have graced the Chelsea and other exhibitions have been nothing short of a revelation to many who have hitherto looked askance at annuals and regarded them with feelings of contempt. It is, of course, true that for nearly a century vast quantities of annuals have been sold and used to decorate countless thousands of small gardens, both in town and country, but in our great gardens and our public parks they have been but sparingly used, and more often than not only as stop-gaps.

Now a change is becoming apparent everywhere, and such time-honoured plants as the Fuchsia, Calceolaria, Geranium, etc., are giving way to Salpiglossis, Larkspurs, Nemesias, Clarkias, Viscarias and many other annual plants. For their brief span of life, nature has compensated by giving them a great brilliance and a richness, both in variety and elegance, unsurpassed by those enjoying a longer existence.

Commercially, they are probably of greater importance than our perennials, as seed production is a considerable industry here, on the continent, and in America, and much money, time and labour are devoted to the growing of seeds, and to the raising of new varieties.

All this energy and enterprise, no doubt, meets with its reward in the popularity annuals have obtained everywhere. Constant efforts to produce new colours, forms and types have resulted in improvements in nearly all our best known garden annuals.

Messrs. Sutton and Sons have set the standard of what good cultivation can effect in such simple everyday plants as Salpiglossis, Godetias, Nemesias, Phlox Drummondi, etc. Messrs. Dobbie and Co. have shown the possibilities of Zinnias, Marigolds, etc., while Messrs. James Carter and Co. have displayed Schizanthuses and Clarkias in fine condition, all showing what these plants are capable of in the way of garden decoration. However, we learn but slowly, and it is still true that annuals are often cultivated poorly. Vast quantities of seeds are wasted yearly, and constant reminders are necessary that thin sowing or drastic thinning is the only road to success.

There are certain annuals that are only seen at their best when grown from an autumn sowing. This is now well understood. Among these are included Salpiglossis, Godetias, Phlox Drummondi and Clarkias. The cooler conditions and the slower growth and development seem to suit all those mentioned, and magnificent beds of them are now to be seen annually in our public parks.

More suitable for spring sowing are the Viscarias and Nemesias—two annuals unsurpassed for brilliance, particularly when massed in large beds or borders.

New colours and forms of many of the most popular annuals come to us in battalions in such families as Godetia, Aster, Clarkia, Calliopsis, Eschscholzia, Nemesia, and many others. There is material to suit every taste and for every purpose.

New species and also the re-introduction of old or forgotten ones, reach us much more slowly. Those interested in the geographical distribution of plants know the regions from which they are to be expected. We may expect little of merit from China, that storehouse of fine plants, or from India. Some are hoped for from Morocco, and not a few from the mountains of Mexico, and it may be confidently stated that South Africa will, in the near future, provide us with some wonderful new annuals, surpassing anything yet introduced from that country.

The late and lamented Mr. Dummer, who had travelled widely in Africa, has left it on record that in Namaqualand there awaits anyone who will take the trouble to reap it, a rich harvest of annual plants of the most showy and decorative character, and beyond anything to be found in any other part of the globe. In a letter recently written by one of the most enthusiastic of South African gardeners, the following passage occurs: "If I am again able to visit Namaqualand, I will collect new annuals of the most wonderful brilliance and beauty, and in variety undreamed of."

I am here reminded of the Editor's instructions, which are to the effect that the purpose of these notes is to call attention to the more recent additions to annual flowers, and it will be conceded that in Venidium fastuosum —so finely illustrated in the coloured supplement plate that accompanies this issue—we have a plant of outstanding merit. Its brilliant orange flowers, four inches across—and often more—with shining black centres displayed to perfection in a setting of soft grey, woolly foliage, make this a most desirable addition. It has been decorated with the R.H.S. Award of Merit, and favoured with a place in the *Botanical Magazine*.

An Award of Merit has also been given to Ursinia anthemoides—a lovely orange Composite, the handsome flowers of which are relieved by a crimson zone. This has been much admired and is now obtainable from all seedsmen. Ursinia anthemoides is dwarf in stature, and when well massed makes a most showy bed. It is very variable from seeds, and requires the selecting hand of the seed-grower to fix the best forms. It is certain to become a popular annual when better-known.

The re-introduction of Arctotis breviscapa adds another first-class plant which is suitable for a dry, hot bank, where for months it will show to great effect. A coloured plate of this species was issued with *The Gardeners' Chronicle* for July 7, 1928.

From Utah has come Baileya multiradiata, one of the neatest and most perfectly formed of golden Daisies—a very lovely plant which, unfortunately, refuses to set seeds with us, but these ought to be obtainable from American seedsmen.

Mr. Robinson, gardener at Villa Serana, Vinadel Mar, Chili, has sent seeds of Godetia amoena or a near ally of that species. This was also brought home by Mr. Clarence Elliott, and a most charming plant it is, about two feet in height, producing fine sprays of soft mauve flowers.

While on the subject of Godetias, reference must be made to the three or more new varieties shown in August last by Messrs. Sutton and Sons. They are magnificent additions to this popular and showy family, and those who prefer species to garden forms may be reminded of the charms of Godetia viminea, generally sold under the name G. Lavender, which is, perhaps, the most lovely of all.

The re-introduction of Sabbatia campestris, a plant from the swamps of Florida (see *Gard. Chron.*, Aug. 7, 1926, p. 107, Fig. 56), adds another interesting subject to the annual border. It is somewhat slow and difficult in its early stages. It should be sown early in the year and on no account allowed to become dry. When of sufficient size to plant out, it will suddenly take a spurt and soon form nice, shapely bushes which give a long display of lovely, rose-pink, star-pointed flowers. It will always be a plant requiring care and skill to make it give of its best.

Oenothera trichocalyx is probably a perennial in its native Californian habitat, but with us it is best treated as an annual. Seeds of this plant are now available and it is one of the best Oenotheras yet introduced, with large, pure, white, sweet-scented flowers which remain open all day. It forms a delightful bed, and is also very ornamental as a group in the herbaceous border (see *Gard. Chron.*, Nov. 6, 1926, p.366, fig. 165).

Dimorphotheca pluvialis is an old favourite, but is now quite surpassed by the variety ringens. This is a great improvement on the type and prodigal with its lovely blossoms, which are enhanced by a broad ring of the richest purple. It should be included in every collection of annuals, and it is now easily obtainable.

Having seen the new annual Anchusa Bluebird, I can thoroughly recommend this newcomer, offered this year as a novelty. In the mass, this is a most telling and effective plant, and of a colour all too scarce.

Poppies are among the indispensables, and one comparatively new strain raised, I believe, by Messrs. Stark and Son, and named Ryburgh hybrids, has not received nearly the appreciation it deserves. Shirley Poppies are notoriously difficult to transplant, but this can be done if they are handled when very small, and the weather is just right, but Ryburgh Poppies may be transplanted as easily and as safely as Polyanthuses, and are now much used in our parks. If sown about the end of September and transplanted into a nursery bed, they grow all the winter and may be placed in their flowering quarters in spring. They will produce a brilliant display there for months, and, as they make big clumps, should be planted two feet apart.

Antirrhinums have now reached a stage of perfection and variety that it must be difficult for raisers to find anything to surpass existing sorts. The new variety, C. H. Herbert, raised by Messrs. Simpson and Sons, of Birmingham, is, however, one that immediately arrests attention, being of a rich reddish-orange—a shade quite new in the family. It is a variety of great vigour, carrying massive spikes of flowers, and a striking plant well worth a prominent place in the flower garden.

And lastly, there is a pleasant remembrance of Heliophila linearis, a really good member of a large and rather weedy genus of South African plants. It sends up a single, straight stem, about twenty inches in height, which branches freely, and remains smothered in a mass of lovely Forget-me-not-like flowers for many weeks. It is a Crucifer and, as its name denotes, its leaves are very small and insignificant. This is an annual of great promise, and no doubt will find its way into general cultivation in due course. *T. Hay, Hyde Park.*

INDOOR PLANTS.

LAPAGERIA ROSEA AND ITS VARIETIES.

The Order Liliaceae is particularly rich in plants having flowers of beautiful form, with petals of considerable substance. These characteristics, combined with handsome, evergreen foliage, render the Lapageria one of the most desirable of all climbers. It will grow freely in any ordinary cool greenhouse, even under frosted glass or in semi-shaded corridors, and is so nearly hardy that in the most favoured parts of Great Britain fine specimens may be grown on open walls facing north. Its love of shade from the direct rays of the sun is not surprising, as my son, Mr. H. F. Comber, describes it as rambling over the undergrowth, beneath the shade of tall forest trees in Chili, from whence it was introduced in 1847.

Although well-known, it is only occasionally that a really good specimen of Lapageria is met with. Yet, if certain essentials are provided, viz., good drainage, suitable soil, sufficient shade, and a moist atmosphere, there should be no difficulty in growing it. A plant in good health should be capable of covering wires or trellis twenty feet at least in every direction. The size of the growth determines the number of flowers at its apex, varying from eighteen or more to only two or three on the older and weaker ones. The waxy, pendant flowers appear from September to December, when most other climbers are past their best. The coloured varieties vary from pinkish-red to the richest red imaginable, but the shade can hardly be described as crimson. Lapageria rosea var. alba, the pure white form, and a fit companion for the foregoing, has slightly larger leaves and grows even more freely.

When purchasing stock, avoid stunted plants; a healthy example, however small, is preferable. Repot as often as the roots spread outwards around the ball of soil, twice or three times in a season, using, while the plants are small and often repotted, good, fibrous peat, with a twentieth part of coarse sand. Later, when planted in its permanent pot, tub or border, it is best to add a considerable proportion of light turfy loam and broken charcoal; peat alone is apt to become sour—a sodden, unaerated condition is detrimental to root-action. Provided there is an outlet for water below, twelve inches of broken brick, closely covered with turves, will efficiently drain soil placed above it.

Forty years ago, when specimen plants were in fashion, Lapagerias, grown in pots, were trained out on the greenhouse roof during summer to make their growth. In August they were taken down, and retrained on wire balloons with the flowers disposed at equal distances, for the decoration of the conservatory or exhibition. Nash Court variety was the favoured red; the flowers were rather short in the tube, open at the mouth, and of an exceptionally fine colour. There was at one time a good specimen of this variety at Warnham Court, near Horsham. Possibly, L. rosea var. superba, now considered the finest, is the same thing under another name.

Perhaps the most important item of cultivation is the care of the young basal shoots. Several of these are produced annually, according to the size of the plant. If they do not appear regularly, remove the surface soil until the cause is discovered. Slugs are particularly fond of the young growths, eating out the points, time after time, before they can reach the surface. A covering of sharp sand for these shoots to grow through is the best remedy; fluffy cotton-wool, tied around, will protect them at the surface, and a regular examination with a good lamp and a pair of sharp scissors can be recommended. In the open air powdered alum or or alum in solution may be used with good effect.

Pruning, after flowering is over, consists in removing all old or exhausted stems, and slightly thinning the remainder if necessary. Wires strained about a foot below the glass and the same distance apart, are excellent to train on. Winter training is simply looping the growth to the wires after pruning, four or more growths to each wire. Summer training is a different matter; strong, leading shoots may be easily looped to the wires, but there still remains a crowd of small growths, which soon become matted together if neglected. This can be prevented by giving each shoot something to twine on. Tie tar-string, at intervals of nine feet, transversely across the wires; then twine can then be stretched at three inches apart parallel to the wires. The small growths will require no tying, only guiding once or twice a week in the growing season, to the twine, around which they soon cling. In September, the strings should be cut, and all growth up to eighteen inches allowed to hang downwards. A very fine display of flowers is thus assured.

A neglected plant, on the other hand, soon becomes a mass of tangled shoots, twined around each other, the wires, or any other support within reach.

The writer, as a young foreman, once had to deal with a large specimen in this condition; it had evidently been well cared for a year or so previously, as it covered the roof of a span-roofed greenhouse sixty feet by twenty feet. Working on a scaffold of planks, we attempted to untwine and lay it out—a practical impossibility. We then conceived the idea of coiling all the growths as they were untwisted, foot by foot, and very soon numbers of small coils were hanging from the wires across the end of the house. Their number diminished rather than increased as the work proceeded, for on reaching a fork, the secondary coil was tied safely to the larger one. This method enabled us to extricate twisted stems from the worst entanglement; it also simplified the operation of retraining, and prevented damage to the brittle foliage.

General cultivation is simple; water should be afforded judiciously in winter and freely in summer, damping the floor in warm weather, and syringing the foliage thoroughly as the sun declines. Green fly may be destroyed by fumigation. A small, white scale is sometimes troublesome, but may be eradicated by spraying regularly with nicotine soap from February to May. Mealy bug should be kept at bay by "quarantining" the plants when received, and giving all undesirable "stowaways" a dose of methylated spirit on the point of a camel-hair brush. *J. Comber, Nymans Gardens, Handcross.*

HARDY FLOWER BORDER.

ARGEMONE GRANDIFLORA.

This beautiful Perennial Poppy does not succeed in every garden, although why it fails to do so is difficult to state, as it is a good perennial and would appear to be quite hardy. Like a large number of the members of the Natural Order Papaveraceae, Argemone grandiflora (Fig. 36) is a sun-lover, therefore it should be planted in a warm position in the border, in deep, well-drained soil that is not too rich or heavy in texture. Provided with such conditions it should flourish and prove a handsome feature, for when happy it forms a bushy plant up to three feet in height, attractive both in foliage and blossom. Its sinuate, spiny-toothed, smooth and glaucous leaves are white-veined, while the large flowers, produced in loose panicles during early summer on established plants, are clear white, with a prominent central cluster of golden-yellow stamens.

A. grandiflora, a native of Mexico, from which country it was introduced to English gardens in 1827, is best raised from seeds sown under glass early in the year, or in the open garden during early spring, and plants so raised should flower in the early autumn of the same year. *F.*

INULA ROYLEI.

This, among Inulas, is one of the choicest, and is a valuable plant for the herbaceous border during August and September. It reaches a height of from two feet to three feet, and has large basal leaves. The flowers, of a beautiful golden-yellow colour, are an attractive feature during late summer and early autumn. *F. W. G.*

POLYANTHUS BARROWBY GEM.

The fine new Polyanthus Barrowby Gem which is achieving such popularity as a spring and summer-flowering subject, will probably acquire a reputation for winter-flowering as well, if one may judge from its behaviour this winter. With me it is flowering freely at the present time, and its large, golden flowers are much valued. This winter has not, so far, been favourable for the production of flowers by those plants which frequently give a good deal of winter bloom, although the Primula Juliae hybrids have been doing well, therefore those of P. Barrowby Gem are very welcome *S. Arnott.*

BULB GARDEN.

CROCUS BIFLORUS.

Crocus biflorus has long been grown in English gardens, and is one of the most suitable sorts for planting in large groups for producing bold effects early in the spring. It is sterile, but increases rapidly by offsets, which it produces freely, while it is one of the most adaptable Crocuses, flourishing in any type of soil, provided it is not waterlogged.

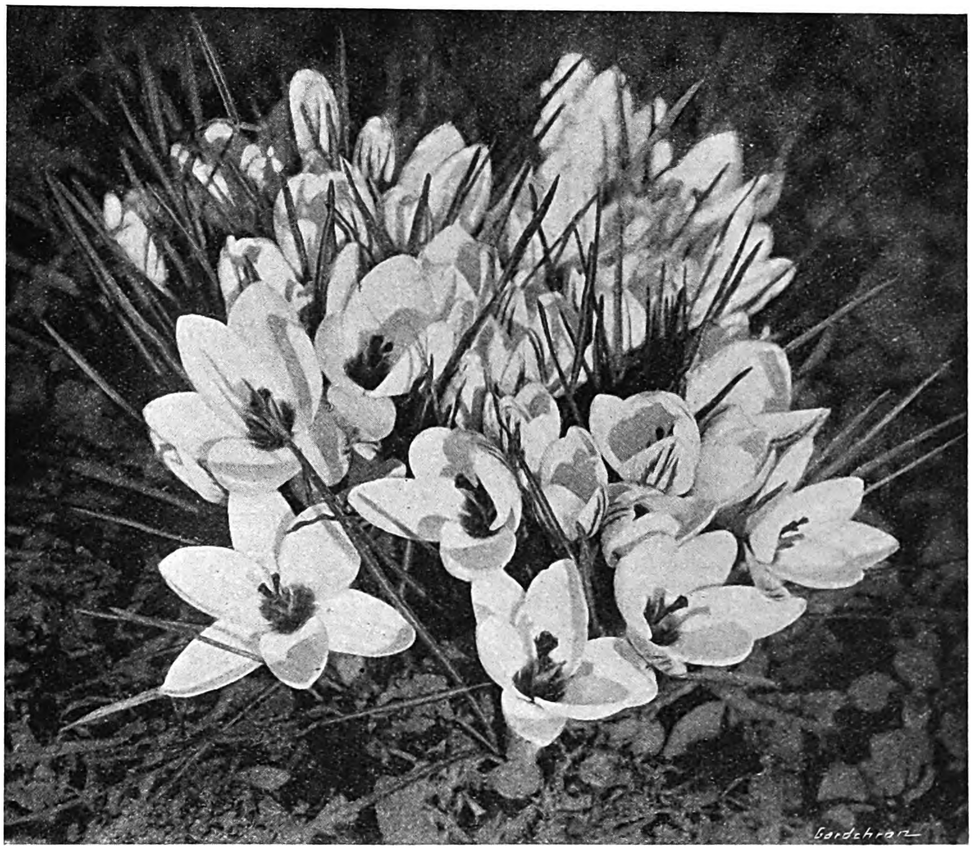

FIG. 38.—CROCUS BIFLORUS.

The type—there are several distinct varieties—may be recognised by its large flowers, the general colour of which is white; the throat is yellow, while the outer sides of the segments are marked and feathered with bluish-purple.

Mr. E. A. Bowles, in his *Handbook of Crocus and Colchicum*, mentions several distinct varieties of C. biflorus. C. b. Parkinsonii is smaller than the type, from which it may also be distinguished by the outsides of the outer segments, being shaded with creamy-buff; the flowers are rounder, pure white within, with a rich orange throat. C. b. argenteus may be distinguished by its narrower segments, which are pale lilac within, while there are only three, instead of five, purple lines on the outer segments. C. b. Weldenii is described as a very attractive form from Dalmatia, ranging in colour from pure white, through forms in which the outer segments are flecked with blue, to those in which the entire outside surface, except for narrower margins of white around the segments, is rich purple.

TREES AND SHRUBS.

A JAPANESE AZALEA.

Mr. ALFRED UNGER, who has travelled extensively in Japan, cultivates many Japanese subjects in his garden at Heidelberg, and has sent us a photograph of a charming scene (Fig. 75, p. 37), wherein a Japanese Azalea figures beside a Japanese stone lantern. Mr. Unger informs us that this Azalea has been in his garden for eighteen years; he considers it belongs to the ledifolia group, but has purple instead of the usual white flowers. It has never received protection, and it flowers profusely each season.

MAGNOLIAS.

THE genus Magnolia, comprising some twenty or more species of mostly deciduous trees and shrubs, is one of the most magnificent groups of spring-flowering subjects. They vary in stature from the fifty or sixty feet, which is often attained by the rapid-growing North American species M. acuminata, to the five or six feet of the slow-growing Japanese species, M. stellata, and give a succession of flowers from March to June. They may be considered of easy cultivation, but should be planted in deep, moderately rich soil, and it is advisable to select positions screened from the early morning sun, particularly for those early-flowering species which blossom before the foliage expands. Most of them are impatient of root disturbance, and extreme care should be exercised in the transplanting of larger specimens. The genus Magnolia has been revised recently, but to avoid confusion, the species given below are under the names in general use.

M. acuminata is a vigorous-growing tree which soon makes a large, spreading head. The flowers are of a greenish-yellow colour, three or four inches in diameter, but are not produced freely on young trees.

M. conspicua is an extremely valuable species from China, and there are a considerable number of good specimens of this fine Magnolia in this country. It is sometimes planted against a wall and trained, but is better grown where it may develop naturally, and frequently makes a shapely tree some thirty feet in height. Its large, pure white, cup-shaped, fragrant flowers are produced in rich profusion in early spring, forming a sheet of white and presenting a most striking and beautiful appearance.

Among hybrids with M. conspicua parentage may be mentioned M. Lennei, a wide, spreading tree with large, richly coloured, rosy-purple flowers, and M. Soulangiana, a popular plant with large, white blooms tinged with purple.

M. glauca is a desirable species and is practically evergreen, at any rate, in the southern counties. A native of North America, it is quite hardy in this country and makes a small tree from fifteen to twenty feet high. It flowers somewhat later than most of the Magnolias, its creamy-white, globular, deliciously fragrant blossoms being frequently produced so late as August and September. M. obovata is a dense-growing, shrubby, Chinese species with large, obovate, deep-green leaves and large, fragrant flowers, heavily flushed with purple. It seldom exceeds five feet in height, but is an attractive shrub.

M. macrophylla is a handsome North American tree with very large leaves and smooth, white bark. It grows to a height of fifty feet in its habitat, but seldom attains more than thirty feet in this country; it is somewhat tender when young, and should be planted in a sheltered position. Its creamy-white flowers are eight or ten inches in diameter and sweetly-scented. M. parviflora is a handsome small tree from Japan. The flowers are almost globular, the pure white petals encircling a central disc of conspicuous, rosy-crimson stamens.

M. stellata is a distinct and charming, but slow-growing, Japanese shrub, and one of the earliest to flower. The pure white, semi-double, fragrant blossoms appear in March, before the leaves expand, and present a sheet of white which becomes slightly tinged with rose as the flowers age. There are several lesser-known species which are attractive, notably M. Dawsoniana, a Chinese species closely allied to M. conspicua; M. Wilsonii, also from China, which has an affinity to M. parviflora, and M. Watsonii, a Japanese small tree with creamy-white flowers possessing crimson anthers.

M. grandiflora, the so-called Laurel Magnolia of the southern United States, is a general favourite, both as an evergreen tree and as a flowering plant. It is generally grown against walls in this country, and usually does best in recesses between bay windows or buttresses on high buildings where good shelter is afforded. It is a very heavy-foliaged tree, and the large branches should be securely attached to the wall, or strong winds may break them off. If the main branches are securely fastened, however, the side growths may be left in a more natural state, supporting only the longer ones by loosely tying them to the main shoots. It is generally considered that this is a slow-growing tree, but if sites are well-prepared and provided with good, rich compost, growth is comparatively rapid after the plants have become established. The flowers of this grand species measure up to one foot in diameter, and are freely borne on old trees, while the bright, glossy leaves are attractive at all seasons. There are several varieties of this species, but few of them are superior to the type. M. g. Exmouth variety is, however, reputed to be hardier. It is rather more compact and erect, and flowers more freely in the young stage. *W. A.*

ERINACEA PUNGENS.

OFTEN called the Hedgehog Plant, owing to its close, compact habit, and long, sharp, silvery-green spines, with which it it densely covered, Erinacea pungens is perfectly hardy in most parts of the country, and is a subject that all who have a rock garden should endeavour to grow. The growth is slow, but in a few years, if left undisturbed, it makes a most attractive cushion on which, during summer, are produced large, Pea-shaped flowers of a charming lavender-blue colour. It roots freely from cuttings inserted during early summer under a bell-glass and kept close and shaded for a time. *F. W. G.*

ALPINE GARDEN.

ACAENA MICROPHYLLA.

A NATIVE of the sub-alpine regions of both islands of New Zealand, in which country it is familiarly known as the Small-leaved Bidi-bidi, this plant is a popular subject for alpine gardens in this country, being the most attractive member of the genus and not so rampant or coarse in growth as some of its congeners. It is often supplied by nurserymen, and sometimes given as synonymous with A. novae-zelandiae, but is quite distinct from that species, and more attractive in its colouring.

It is an extremely useful carpeting plant, clothing the ground with close mats of tiny, pinnate leaves, almost feathery in effect and of bronzy colouring, while in late summer and throughout the autumn the carpets are thickly studded with sessile, round flower-heads, and fruits bristling with bright crimson spines like miniature hedgehogs.

A. microphylla is useful for a variety of purposes. It may be used as a carpet plant to Crocuses and similar subjects, whose flowers may be marred during rainy weather by coming into contact with the soil, or it may be planted in the interstices of stone-flagged walks, while it is excellent for clothing hot, sunny banks.

It is a sun-lover, and is never so happy as when growing in light, poor soil, in a hot, dry position, as under such conditions its rich colouring is brought out and accentuated. A. microphylla is quite hardy and may be thoroughly recommended where plants for such conditions as described above are desired. *Kent.*

AJUGA METALLICA CRISPA.

THE majority of gardeners and plant lovers are familiar with the variegated and purple-leaved forms of the common Bugle, A. reptans, and to a lesser degree with the attractive A. pyramidalis and A. genevensis, but it is seldom that A. metallica crispa is encountered in gardens, and still more rarely is it described in horticultural literature. In the Kew *Hand List of Herbaceous Plants*, a variety of A. reptans is given as metallica, and it is possible that this is the correct name of this subject, although no authority for the name is given, nor any other references for that matter.

It came, in the first instance, from Germany, but when, and by whom it was introduced, I have been unable to discover, yet for all the meagreness of information about it, it might well be employed more extensively on rock gardens, or in any position where prostrate, low-growing carpeting subjects are required.

The striking feature about this Bugle is its foliage, which is quite distinct from that of any of the other members of the family, being very curled and wrinkled, dark and glossy, and with a distinct metallic sheen. It forms an extremely dense mat of foliage, the curling of the leaves accentuating this density. The flowers of A. metallica crispa are typical of the genus, being of a clear, bright blue colour, and produced—not so freely that the effect of the foliage is marred—in short, leafy and close packed spikes. To secure a full effect from the foliage, this subject should be planted in a comparatively sunny and not too moist position, so that the metallic sheen of the foliage may be developed fully. Inclement weather has no effect upon it, and that it will thrive when once planted may be guaranteed, while it may also be used with effect—grown in a small pan—in the furnishing of the alpine house.

OXALIS LOBATA.

ONE of my greatest treasures in the rock garden during the past season was Oxalis lobata, the charming little dwarf species from Chile, although whether it is still alive, or will manage to survive the remainder of the winter, I hardly dare to hope, for it is notoriously a "bad doer" and is not enamoured of our winters, which is understandable when one considers it hails from Chile, and has seemingly pined to return to its native land since its introduction in 1823.

I was fortunate in securing a good specimen last spring—despite the difficulty attached to retaining it alive it is still stocked by one or two of the leading alpine plant nurserymen—and planted it in a gently sloping moraine, surfaced with a good layer of clean granite chips. It was planted clear of any rocks, so that it received all the available sunshine, and rain, but the latter soon drained away. and the "neck" of the plant was not subjected to too much dampness. And under such conditions Oxalis lobata flourished, sending up leaf after leaf throughout the summer, until finally it became a small, rounded hummock of rich green foliage.

In September, the flowers appeared in profusion, rich golden-yellow in colour, and borne singly on slender stems of up to about one-and-a-half inch in length. The whole plant, when it does well, has an air of refinement and daintiness about it, for its small leaves, each composed of three deeply-lobed leaflets, carried on short, slender stems arising directly from the bulb-like root-stock, are of a vivid and refreshing green, while the blossoms are rich in their colouring, and of perfect form.

But it is seldom that O. lobata proves a success. The late Mr. Reginald Farrer regarded it with high esteem, but advocated the growing of it only in the most favoured conditions, while Mr. A. T. Johnson, in his admirable book, *A Garden in Wales*, laments the fact that "it has often refused to do so much as peep above the soil" with him.

Whether my plant, heaped over with granite chips and protected to a degree from excessive wetness by a pane of glass placed six inches above it, will survive the winter and prove as attractive this coming season as it was the last, remains to be seen. From my experience of it, O. lobata would seem to require the warmest and sunniest position possible, and a perfectly drained and open rooting medium, such as that provided by a well constructed moraine, with a layer of chips around its "collar" to keep this vital part as dry as possible. Having provided these seemingly ideal conditions, this illusive Chilian may condescend to grow and even flower, but, on the other hand—will the secrets which govern the successful cultivation of this and the many other "bad doers" ever be brought to light? *M. W.*

PROPAGATION OF RHODODENDRONS BY CUTTINGS.

During recent years there has been a tendency for growers to try to obtain Rhododendrons on their own roots in preference to the more general practice of purchasing grafted plants. Propagation by vegetative means—otherwise than by grafting—should be encouraged, and in addition to the better-known and more widely used method of layering; cuttings of many kinds, if of the right type of growth and inserted at the correct time, give excellent results.

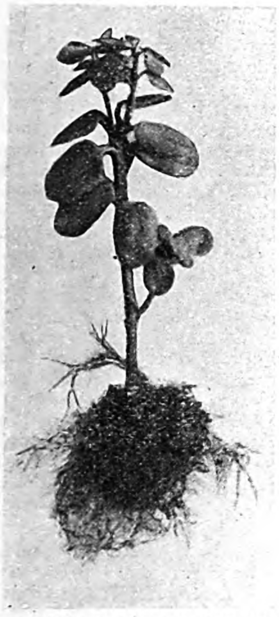

FIG. 39.—RHODODENDRON HIPPOPHAEOIDES VAR.
Inserted July, 1928; photographed January, 1929.

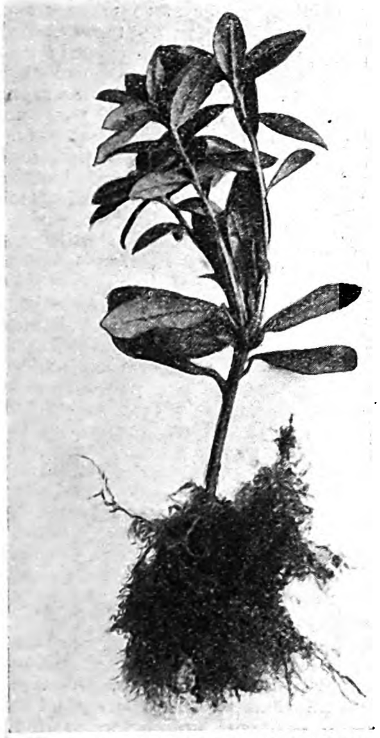

FIG. 40.—RHODODENDRON INTRICATUM.
Inserted July, 1928; photographed January, 1929.

Plants raised from cuttings possess certain definite advantages over those raised by seeds, layers and grafts. Cuttings reproduce the true characteristics of the parent plant, whereas seedlings, even of the true species, vary; and although layers would give plants of flowering size more quickly than cuttings, it is possible to raise many more young plants from a stock plant by cuttings, as only a few of the lower branches of a Rhododendron may be layered. The greatest advantage cuttings have over grafted plants lies in the elimination of the suckering nuisance, which spoils so many Rhododendron and Azalea beds unless they are being constantly attended to and the suckers removed. Unfortunately, it is fully realised that grafting must still constitute the most convenient method of increasing in quantity the majority of our larger and more showy garden hybrids.

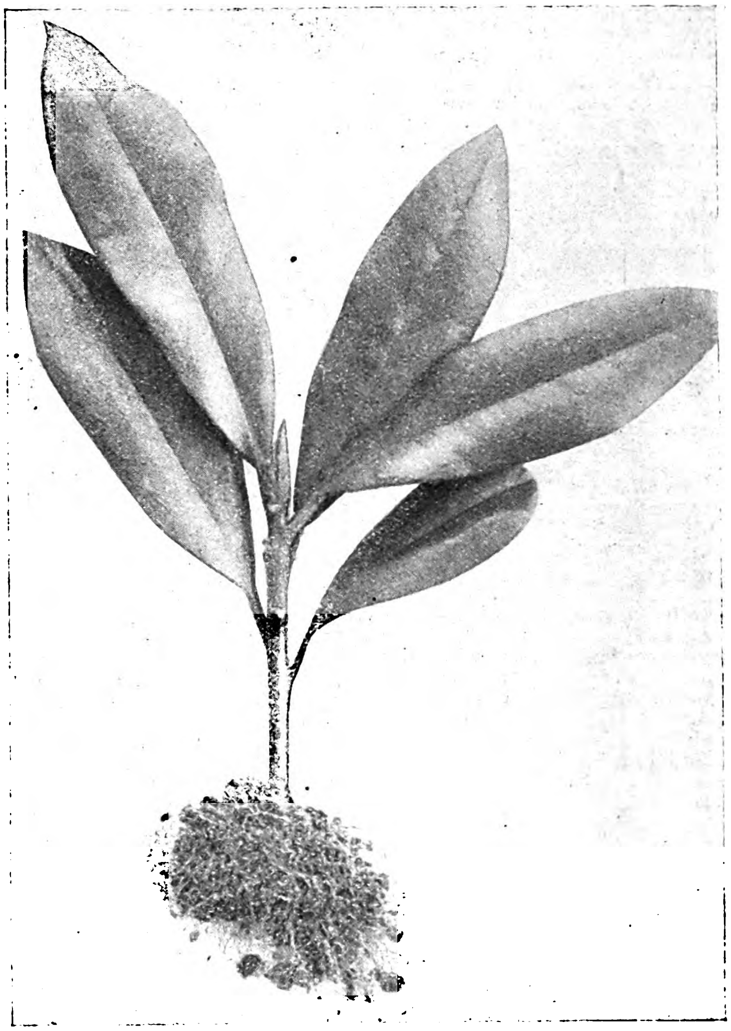

FIG. 41.—RHODODENDRON CUNNINGHAM'S WHITE.
Inserted October, 1928; photographed January, 1929.

During the past four or five years, I have tried the propagation of many kinds of Rhododendrons from cuttings, and found that from the propagator's point of view, they sort themselves out into different groups, the governing factor of each being the time of taking and inserting the cuttings.

The small-leaved Rhododendrons, mainly classified botanically under the Lapponicum series, are particularly responsive to propagation by cuttings, and anyone who has grown such species (as R. achroanthum, R. chryseum, R. fastigiatum, R. flavidum, R. hippophaeoides, R. impeditum, R. intricatum, R. nigro-punctatum, R. orthocladum, R. rupicola and R. scintillans, belonging to that series; and R. calostrotum, R. campylogynum, R. ledoides, R. radinum, R. sphaeranthum and R. saluenense, belonging to other series, must have found that nearly every one of these species has developed desirable forms which are outstanding among the others; therefore, as the perpetuation of the best forms is of the utmost importance, cuttings should be used to increase the stock,

There are two definite periods when cuttings of this group succeed best, and the method employed must correspond to the time of inserting the cuttings.

(1) Cuttings of the young tips should be secured, either with a slight heel of older wood, or at the junction of the current and previous years' growth; these cuttings may be from one to one-and-a-half inch in length, and should be inserted in late June or early July, in a warm frame with a temperature of about 70°, in a mixture of peat-moss litter and sand, and kept watered with rain-water. Cuttings treated in this way will produce roots and be ready for transference to boxes in from three to five weeks; they will make quite an appreciable amount of new growth before the winter sets in. Fig. 39 represents a cutting of Rhododendron hippophaeoides variety inserted in July, 1928, and shows the amount of new growth made between that time and January 14, 1929, when the photograph was taken.

(2) Cuttings of the current year's wood, about one inch to two inches long, taken with a slight heel, in late August or early September, and inserted under a bell-glass in a cold frame, in very sandy peat, will produce roots, and may be left undisturbed until transplanted early the following spring. This method is quite successful with the more vigorous species, such as R. hippophaeoides and R. scintillans, but such species as R. intricatum (Fig. 40), now, unfortunately, becoming a scarce plant, should be inserted indoors. *F. P. Knight.*

(To be continued.)

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar.* 7818.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XII.—OUR FIRST CAMP.

SHORTLY after leaving the bungalow at Theronliang, and proceeding down the Tidding valley, we reached the suspension bridge which marks the limit of administered territory, and crossed to the left bank of the river. The Government cannot quite make up its mind whether to maintain this bridge or to abandon it to the white ants. In its present state of genteel distress, it would long ago have been condemned as unsafe by any self-respecting engineer, but there is really no one here to condemn it, and so, year after year, it hangs together, like Kipling's tramp steamer,

> "Just a pack of rotten plates, puttied up with tar!"

and is used by hundreds of Mishmi coolies coming into Sadiya for the open season. One day it will fall down, and then Government will close it; but there are signs of possible action in the near future, and this vital link with the Mishmi Hills may be forged anew. Anyhow, we crossed in safety, and went on down the Tidding valley, sometimes in jungle, sometimes over boulders in the river bed. A tall tree which I saw now for the first time, and more frequently during the next few days, was Acrocarpus fraxinifolius, its bronze flowers scattered over the ground in prodigious amount, without affecting the appearance of the tree in full bloom. The flowers, although in build typical of the Leguminosae, have only five stamens, and are borne in long, compact spikes. Most of the flowering trees were leafless; but a few were putting forth their reddish-orange leaves, and it was often difficult to tell which were flowers and which leaves, so closely do their colours match.

A few Orchids were beginning to bloom, including Dendrobium nobile, and I noticed also plants of Vanda and Cymbidium.

Leaving the Tidding valley, we crossed a shoulder of the mountain, and found ourselves in the steep-sided narrow valley of the Lohit, perhaps a thousand feet above the river; and soon afterwards we camped in a confined space on the path. For another two days we marched through the dense jungle, which, as the trees showed, was composed chiefly of typical Indo-Malayan species. Among the commonest were the following: Terminalia myriocarpa, Pterospermum acerifolium, Kydia calycina, Acrocarpus fraxinifolius, Duabanga sonneratioides, Castanopsis indica, Engelhardtia spicata, Ficus Cunia, Saurauja napaulensis and Macaranga indica. Less common were Erythrina indica, Elaeocarpus serratus, Grewia laevigata, and the climbers Hiptage Madablota and Thunbergia coccinea.

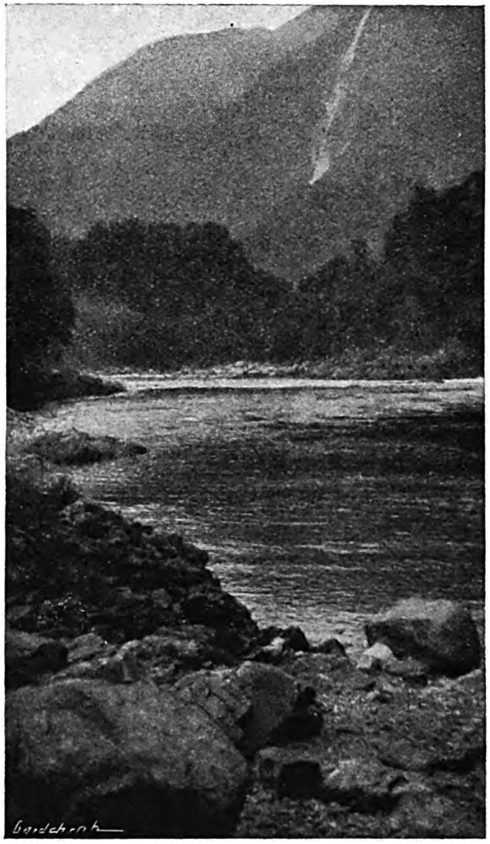

FIG. 42.—THE LOHIT VALLEY, IN THE UNADMINISTERED COUNTRY.

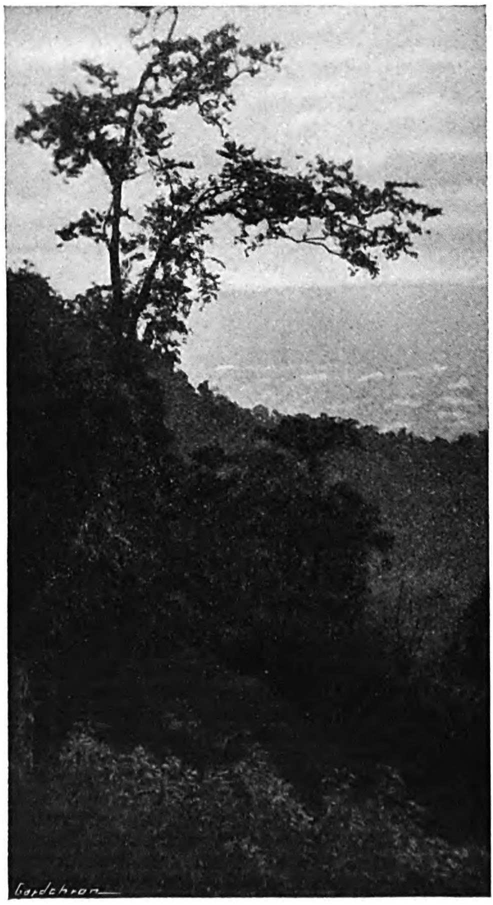

FIG. 43.—HILL JUNGLE AND THE SADIYA PLAIN.

On the second night we camped in the bed of the Lohit, at a delightful spot, and starting early on the 15th, we reached the Delei river, and crossing by the remains of the suspension bridge, found our camp prepared for us in a pasture half-a-mile above the junction of the Delei with the Lohit. Our kit had been stored in a Bamboo hut, and we pitched our tents directly on the high river bank. Eventually, owing to the curiosity of a herd of mithan which grazed here, and paid us nightly visits, we fenced ourselves in.

There were two small villages here, one on either side of the Delei, and a certain amount of arable land, past and present, on the adjoining terraces, while forest clearings extended for 4,000 feet up the flanks of the range to the 6,000 feet level; but mostly the steep mountains which enfolded us were covered with dense forests, although it was clear from an inspection of the highest visible peaks, where snow still lingered, that the belt of Indo-Malayan jungle to which reference has been made, only lined the bottom of the deep valley.

Sparse as the local population was, we were not lacking in company, for every day saw strings of Mishmi coolies returning home from the plains (whither they repair every cold weather to cut canes) for the spring farming. But these people carried loads of their own, so they could be of no service to us, and we had to rely on the local inhabitants, who presently produced the first dozen coolies willing to carry our boxes two days' journey up the Delei valley. So far, I had been on familiar ground, having tramped this way in December, 1926, but under conditions which, in the depth of winter especially, made it impossible to observe much of the forest flora. Our business now was to transport ourselves and fifty loads so far up the Delei valley as possible, over entirely new ground; and during the three weeks we were in camp by the bridge I had ample leisure to look about me and gather a good general impression of the composition of the forest. But this was not easy. In the jungle, all is obscure. The canopy of foliage is far overhead. Everything is smothered up, and in the confusion it is almost impossible to say which leaves belong to which branch. The very trunks are so coated with moss, overlain with a covering of larger epiphytes, that rarely do they reveal themselves; and the way of the seeker after knowledge is beset with difficulties on the ground, lianias to trip over, thorns to tear the flesh, Bamboos to obstruct. Recourse must therefore be had to indirect methods of observation for the recognition of species, and once inside the jungle, it is really more profitable to look on the ground than in the air. Fruits, leaves and flowers can be picked up, especially after a high wind. No fragment, however lonely, need be neglected, as sooner or later a parent will be found for the orphan; for although no two trees in contact will be alike, it is surprising how frequently a species recurs. Gradually other bits and pieces are found, and presently the puzzle can be fitted together.

If now, leaving the interior, we stand on one side of the river in the spring, and look across at the banked rows of tree tops whose billowy domes interlock to form the roof of the jungle, a very different impression is formed. At first, we may be unable to distinguish anything in that massive flood, rolling in ruffled waves, which here and there break and curl into strident colour, but mostly swamp the cliffs in deep seas of bottle-green. But by dint of patience, much may be learnt from such an aerial view, especially with a good pair of field glasses, and one gradually learns to distinguish a sufficient number of species to gain a good general idea of the composition of the forest, supplemented by what one has seen in the interior.

---

VENIDIUM FASTUOSUM.

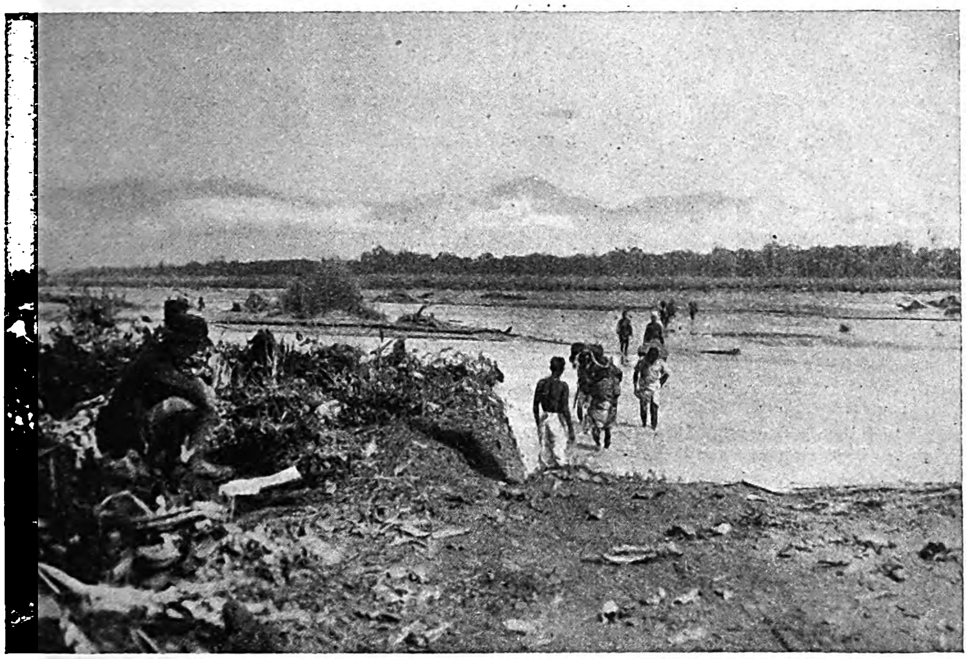

FIG. 44.—CROSSING THE DIGARU; MISHMI HILLS IN THE DISTANCE.

The Monocotyledonous trees—Palms, Pandanus and so forth, may be picked out at once, and so too can many of the big Palm-like Araliaceae, such as Trevesia palmata, Heteropanax fragrans and Brassaiopsis. A few, a very few, trees will be in flower, or at least in such buoyant flower as can be recognised at this distance. Such are the cardinal red of Erythrina indica, the reddish-bronze of Acrocarpus, and the white-cloud puffs of Derris robusta. (This last was abundant, but difficult to get at; after several abortive attempts, I at last reached a tree and picked up some fallen flowers. Except that they were smaller, with a more hairy calyx, they did not differ materially from those of D. robusta collected a month earlier at Pasighat.)

Other trees can be recognised on sight by some peculiarity of foliage or habit—for instance, the enormous, fidgety leaves of Pterospermum acerifolium, a deep sonorous green above, but displaying their almost white undersurface as the breeze catches them and turns them over. A few trees are leafless, even at the end of March, among them a large Sterculia, with several capsules still clinging to its bare boughs—it must shed its leaves in response to the cold weather of December-January, rather than to the hot weather of April-May. But most of the deciduous trees are conspicuous now for their new raiment, the sharp greens and acid yellows, and warm reds of spring foliage, which chime and ring melodiously against the deeper note struck by the evergreen forest. A small Sterculia with hanging flowers of coral-red, is coming into leaf, and an Ash is already fully clothed in shining new leaves. Two other trees, one conspicuous for its fresh green, rather Lime-like foliage (possibly Grewia sp.), the other for its tall, straight trunk and smooth, pale bark, I could recognise anywhere, but in the absence of flowers, was unable to name, although I believe it to be Lagerstroemia parviflora. In the thickets and pastures along the river bank were many interesting trees and shrubs. Glycosmis pentaphylla, with snow-white flowers, filled the air with fragrance, but was more than rivalled by the climber Caesalpinia Nuga, whose pyramids of gamboge flowers put up a perfect barrage of scent. There was a large number of climbing plants, some scrambling, some twining, some really climbing with the aid of tendrils. Woody climbers are typical of the tropical rain forest, as opposed to the temperate rain forest, whereas epiphytes are just as common and almost as varied in the latter as in the former. Among the many climbing plants seen were: Hemidesmus indicus and several other Asclepiadeae in fruit; Aristolochia Roxburghiana (or an allied species); Jasminum scandens, and another species not in flower; Schizandra propinqua, in which the filaments of the male flower are united into a small, fleshy dome, with tiny ports, out of which peep the yellow anthers; Sabia sp.; Smilax spp.; Aspidopterys sp.; Vitis spp.; Millettia cineria; Clematis sp. and Bauhinia sp. not in flower; Combretum sp.; Ventilago, Porana, and the semi-climbing shrub Dalbergia tamarindifolia, its branches tightly packed with small, sulphur-yellow flowers. In addition to these were several Menispermaceae (Stephania and others), and the ones previously mentioned.

Along the river bank, also, where the mithan had driven paths through the scrub, a large and peculiarly pungent Zanthoxylum, like Z. acanthopodium, was common, growing with Ash and Glycosmis, and a small bushy Sophora with pale yellow flowers and scarlet seeds in its moniliform pod. Here, too, among the scattered trees, a small Stereospermum—not S. chelonoides, for it had bipinnate leaves—was frequent, with the more common Engelhardtia spicata, which sometimes at least sheds its leaves on one side while it is growing new ones on the other, so that it is never quite bare; this Engelhardtia is always easy to recognise in fruit, by reason of its long, fat swish-tails. Bischofia javanica was also fairly common, an untidy tree at this season, half disrobed and with no apparent preparations for a change of clothing.

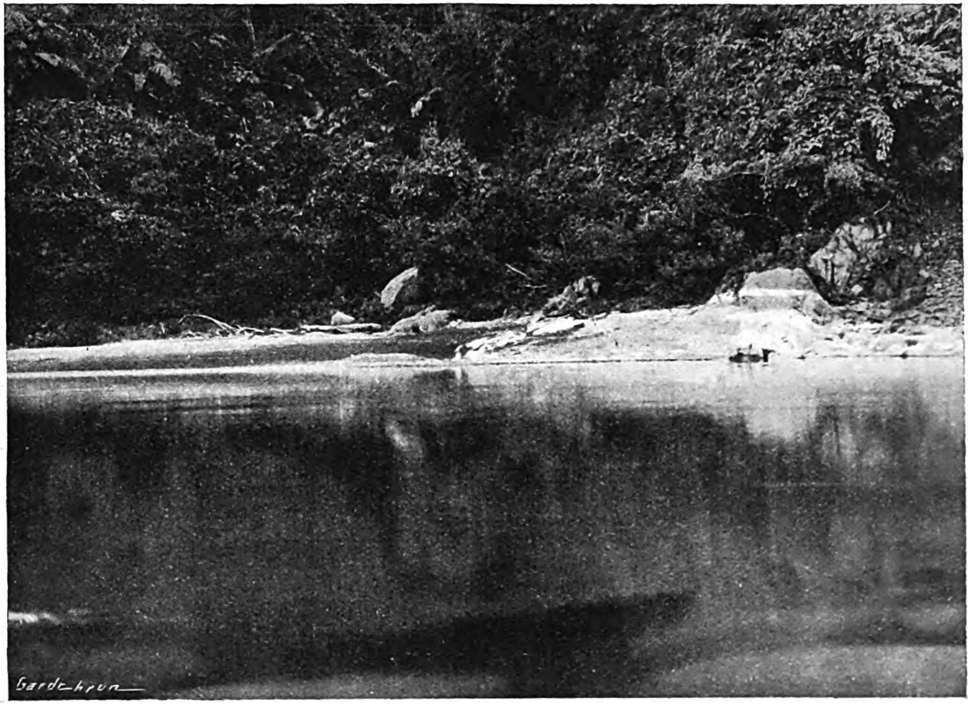

FIG. 45.—A GOOD FISHING POOL ON THE LOHIT.

By March 22, twenty-four coolies had started up the Delei with loads; and then came the rain, which put a stop to everything. *F. Kingdon Ward.*

PLANT HISTORY IN NOMENCLATURE.

(*Continued from p.* 14).

The Romance of Tea.

Is there any other plant-name which is so widely known, so universal, popular and welcome as that of the Tea? It has found its way into every land, and wherever it goes it stands for the cup that cheers but does not inebriate. True, the cup is sometimes almost a solid one, for in very cold lands where fat is needed the tea is made into a kind of soup, gruel or other semi-liquid, semi-solid food, which answers for meat as well as drink!

While a score of different plants are in use in one part of the world or another as substitutes, there is one which is pre-eminently the Tea plant. Mountain Tea, Sweet Tea, Brazilian Tea, Bush Tea, Maté, Yerba or Paraguay Tea, and many others might be named, but they all acknowledge the supremacy of the Chinese name for the Thea Bohea, of Linnaeus, now usually referred to as Camellia Thea, and known in several distinct varieties.

It is not necessary to go into details respecting orders and genera, species and varieties, but it may be stated generally that Tea is a species of Camellia, a genus of the Order Ternstroemiaceae, and that Hooker thought it possible that the stock is to be found in the wild plant of Assam, which has been named Camellia theifera. With other botanical names and theories we do not here trouble ourselves, nor need we enter into the question of distribution, or relate the legends which have grown up around the plant in the course of centuries.

The name Tea is pure Chinese, and with this and its derivatives we will now proceed to deal. The student who is unfamiliar with the vagaries of a Chinese dictionary and the peculiarities of picture writing may be excused if he finds some difficulty in the study of the word. It should be remembered that there are many dialects in China, and that, while the written form of a word is fixed and definite—the pronunciation may vary greatly. Thus the word-picture for man resembles an inverted capital V, thus Λ, and represents his two legs; yet it is pronounced *jen* in one place, *yan* in another, and *ren* in another. So is it with the word for Tea. In Canton, for example, it is called *ch'a* with an aspirate, yet this is the same as the *ta*, *tay*, *thè*, *cha* and other forms to be met with in other parts of the country and in other lands.

These various pronunciations are of value in relation to commercial history, since they show that we received our first consignments from a district where it was named *Tay* or *Thé*. It is well-known that frequently Tea was formerly called Tay in this country, and that during living memory the pronunciation has undergone the change which is represented by these two modes of spelling the word. It is possible that our English pronunciation was at one time affected to some extent by the French, but this is a question for later consideration.

The Chinese picture-word for Tea is derived from the radical which represents herbs and plants, and a second symbol usually pronounced *To*, which made it clear that a plant was intended, and suggested the sound to be employed. From this it seems clear that the Chinese did not introduce Tea from abroad, but knew it long ago as a native plant, and used it from early times as a beverage.

From the *Flora of China*, published some years ago by the Linnean Society, we learn that fourteen different native species of Camellia were known forty years since to botanists. The most important of these is the plant now under consideration, which has been described under a dozen different names, such as Camellia Bohea, C. theifera and C. viridis, or Thea sinensis, T. japonica, T. assamica and the like. Numerous specimens from China, Formosa and Japan are preserved in the herbaria, but whether or not the plant is really indigenous eastward of Cachar and Assam is regarded as doubtful, although my friend the Rev. B. C. Henry, of Canton, recorded that the Thea Bohea, L., was really wild in Hainan. What is clear is that various species of Camellia are found in many eastern lands, and that from time immemorial the leaves of one or other of these, but especially of the form known as Thea, have been employed in the making of a much esteemed beverage known as Tea, Thè or Cha. The latter is the form in use in Japan, but it is recognised as an imported term, and from it the Japanese terms for tea-pot, tea-cup, tea-garden and many others are derived, although they have two distinct forms of tea-kettle with different names.

As for the history of the word in other lands, we learn that Tea was introduced into the west towards the close of the sixteenth century, but there is a good deal of confusion, if not contradiction, among travellers, writers, historians and philologists respecting the district whence the name originally came and its mode of introduction into Europe. Giles (*A Glossary of Reference*) states that it was called *Tcha* or *Chaw*, the former being the Cantonese pronunciation, but that our word Tea is from the Swaton and Amoy dialects, where the plant is known as *Tay*. It was so pronounced in early times, and continued to be so called down to the middle of the last century. My grandmother, who died about 1865, always brought out her best *chainey* (as she called her china-ware) when she had friends in for a cup of *Tay*. So Pope wrote—

> "Here thou, great Anna! whom three realms obey,
> Dost sometimes counsel take—and sometimes tea."

Samuel Pepys wrote in 1660 (September 28): "I did send for a cup of *tee* (a Chinese drink) of which I never had drank before." Blount, a few years later (1674), wrote it *cha*, and these two divergent forms are represented by the French *thè* on the one hand, and the Italian *cia*, Neapolitan and Portuguese *cha* on the other.

In our English dictionaries the spelling *tea* prevailed, and in 1742 Bailey gave the following:—

> "*Tea*, a known liquor made of the leaves of a *Chinese* shrub."

Another dictionary of the same period has:—

> "*Tea*, the leaf of an *Indian* shrub, which having boiling water poured over it, and impregnated therewith, and then sweetened with loaf-sugar, is become the universal liquor for the ladies."

Osbeck, a friend and disciple of Linneaus, who travelled in the east in 1750 and was a good naturalist, tells us that the Europeans learned to drink tea in the fifteenth (? sixteenth) century, and since that time "have vied with each other in giving the Chinese the most money for this and other goods which are become fashionable." He adds that Tea grows both in China and Japan, as well as in Tonkin, but that according to Du Halde, the best Tea comes from Fokien. "We have as many names for Tea," he writes, "as there are places where it grows, and different ways of preparing it," and he adds a number of interesting particulars which we have not space to copy.

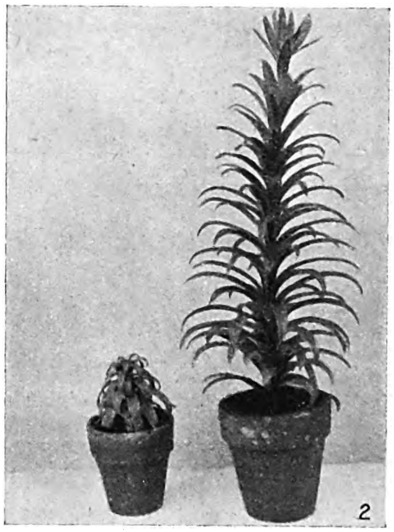

FIG. 46.—ROSETTE DISEASE OF LILIUM.
Left, plant infected in 1926: Right, normal plant from clean bulb, 7–9 inches in circumference.

At one time all Tea was named Bohea after two celebrated hill ranges in the province of Fokien, whence the most famous kind was procured. Thus Pope:

> "To part her time 'twixt reading and bohea,
> To muse and spill her solitary tea;"

And Byron:

> "I must have recourse to black bohea."

The commercial and ceremonial use of Tea, its folklore and other associations, might well fill a volume. Who has not heard of, if he has not seen, the famous brick Tea, so largely used in Mongolia, Siberia and Russia, where it is called Cha (*tscha*), and has been often used as currency, like salt and other commodities elsewhere? One of the most interesting accounts of the growth and preparation of Tea is that by Fortune entitled *The Tea Districts of China and India*, which is not yet out of date. *Hilderic Friend.*

(*To be continued.*)

A NEW DISEASE OF LILIES[*].

Those whose interest in Lilies is sufficiently keen to take them a little below the surface of things, are aware that towards the end of the Victorian era there was a considerable trade in the bulbs of what was then called the Easter Lily, between Bermuda, on the one hand and Great Britain and America, on the other. The history of the industry in Bermuda has already been set out generally in *The Gardeners' Chronicle*[†], and it is sufficient here to point out that, to find its beginning, we must go back to about 1876, when one Harris, a florist of Philadelphia, received some bulbs of L. longiflorum var. eximium from Bermuda, and, recognising the commercial possibilities of the plant, particularly for forcing into bloom at Easter, promptly attached his own name to it. Hence, the Lilium Harrisii of commerce. The incident affords but one more instance of the haphazard way names are given to plants and are retained for years.

The cultivation of this Lily in Bermuda prospered, and in the course of a few years the export trade in the bulbs assumed considerable proportions. This continued until about 1896, when the business reached its maximum, and thereafter commenced to decline. The decline was rapid, and although the export never seems to have entirely ceased, it had reached such a low ebb long before the war that, so far as Britain was concerned, the trade was negligible.

The decay of the industry was primarily due to disease which doubtless had a footing in the bulb fields prior to 1889, as in that year Kean investigated the conditions locally and afterwards published his conclusions.[‡] At the time, as well as for years afterwards, it was called the Bermuda Lily Disease, and in so far as anything was known of it in the early days, it was vaguely supposed that a fungus, which Kean identified with Botrytis, was responsible for what, happily, has since proved to have been only the temporary ruin of the industry. The supposition had some basis of support at the time, in the fact that specimens of diseased material sent by Kean to Marshall Ward were identified by him as attacked by Botrytis. Ward had recently made a study of the fungus on Lilium candidum, and had published the results of his researches.[§]

In those days the sciences of mycology and phyto-pathology were not so advanced as they are now, and for a long time it did not seem to have occurred to anyone that more than one disease might have been present in the Lily fields. At that time, too, although, as we now know, it would have availed little, there was no prophylactic or cure for Botrytis; indeed, it is only within comparatively recent times (1923) that Bewley[‖] has suggested the use of what seems a specific for the fungus, in a two per cent. spray solution of calcium bi-sulphite.

By 1896, the disease had spread to such an extent as to interfere with the growing and marketing of the bulbs. Report after report on the disease was made, but nothing came of them because the real cause was not suspected. Various suggestions as to remedial measures for the Bermuda planters' troubles were made at the time, but no developments followed, and meanwhile the world's markets were gradually lost, mainly to the Japanese, although a modest proportion of bulbs was grown in the Azores. As time went on, it became apparent that more than one disease was at work and that, except, perhaps, in a damp season, Botrytis was not among them as a material cause of the trouble.

In 1915, C. W. Carpenter, of the United States Department of Agriculture, carried out an investigation of a mass of material sent to him by the Department of Agriculture in Bermuda, and his observations went to show that a mosaic disease was present on the plants as well as another disease which the Bermuda planters called the "yellow disease," of which the main external symptom is a noticeable stunting of the habit of the plant. Early in 1925, the attention of the Plant Pathologist to the Department of Agriculture in Bermuda, Mr. L. Ogilvie (now of Long Ashton), was drawn by a Lily farmer to the peculiar appearance of the plants in one of his fields. The plants showed a cylindrical habit of growth instead of the pyramidal habit characteristic of the Lily; the leaves were slightly yellowed and not dark green as they should have been, and the upper leaves curled downwards and were often distorted. It appeared that some weeks previously the plants had been infested with an aphis of sorts, and as the symptoms seemed to be identical with those exhibited by the Lilies investigated by the U.S.A. Department of Agriculture ten years before, it was decided to investigate the matter.

[†] No. 1,996. Vol. LXXXII. March 28, 1925.

[‡] "The Lily Disease in Bermuda," *Bot. Gaz.*, XV, January, 1890, p. 8.

[§] "A Lily Disease," by Marshall Ward. *Ann. of Bot.*, II (1889), p. 184.

[‖] *Diseases of Hothouse Plants*, by W. F. Bewley (1923), p. 65.

Ogilvie soon reached the conclusion that he had to deal with a transmissible virus disease, and searching for the agent of transmission, his suspicions fell on the aphis already referred to. Research followed along the line indicated, and ultimately Aphis gossypii was found to be a carrier of the infection. This aphis infests the hedges of Hibiscus, which are so common in the Bermuda fields, and congregates on the stems of the Lilies soon after they begin to push through the ground in what corresponds to our late autumn. (The plants are usually in bloom in March). By about the middle of December the aphis has done its work and characteristic symptoms of the disease begin to appear in the field, gradually spreading as the months go by. At first the current season's infection is usually apparent in patches about the fields, the patch centering on a plant of stunted growth of which the bulb was infected when planted, and covering about fifteen plants, which form a rough circle around the stunted plant. In some cases, however, the spread of infection is more rapid and covers a larger area.

During flowering time, the lower leaves of diseased plants turn yellow and the stem dies quickly from the base upwards; moreover, plants which have had their vitality lowered by the virus disease, fall a ready prey to attack by a bulb mite (Rhizoglyphus hyacinthi) which infests the soil in Bermuda and burrows into the base of the bulb, causing basal rot in much the same way as the Japanese bulb mite will eat the hearts out of bulbs of L. auratum and others on their passage here from Yokohama. The disease has a marked effect on the size of the bulbs and causes them to split up, until they are ultimately very small and useless for commercial purposes (Fig. 49). In the course of his investigations, Ogilvie had no difficulty in infecting healthy plants with the disease, by using the aphis for the purpose, and the case seems clear.

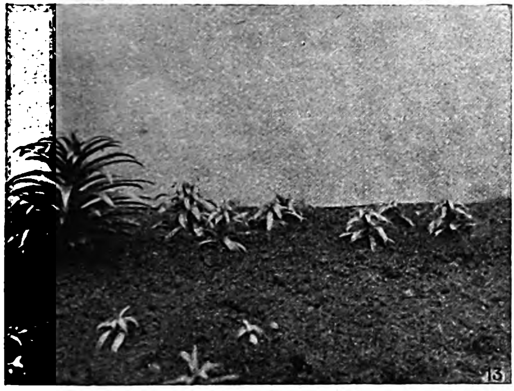

FIG. 47.—ROSETTE DISEASE OF LILIUM.
A "clean" plant among many infected and stunted plants.

Although the point does not seem to have been finally disposed of, it seems possible that other species of aphis found in Bermuda may be released from suspicion of any serious part in the transmission of this disease, so that if Aphis gossypii can be disposed of, the virus disease should disappear. An important point which emerges from Ogilvie's researches is that the disease is not communicated through the soil, nor through contact of a diseased plant with a healthy one; in fact, the "carrier" must be present. On the other hand, once a plant has been infected there is no recovery, and if the bulb is lifted, rested and replanted next year, the tell-tale symptoms reappear. In such cases, however, Ogilvie observed that the symptoms are delayed until about half-way through the growing period.

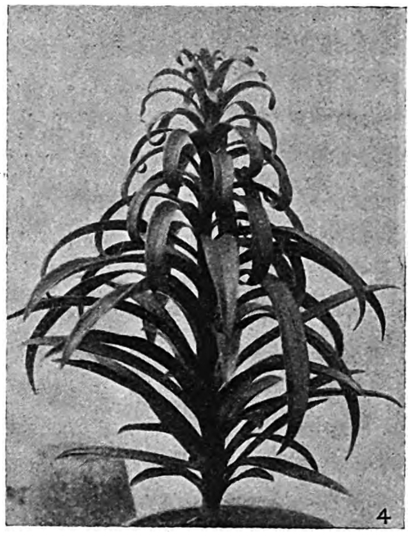

FIG. 48.—ROSETTE DISEASE OF LILIUM.
A plant showing typical symptoms of current season infection by aphides.

This brings us to the conclusion that if the aphis can be controlled, the disease will also be controlled, and although the aphis has a natural parasite in one of the Braconids, and is esteemed a delicacy by various larvae and beetles, some more definite form of control is essential. Happily, this is to hand in nicotine applied in the form of dust, or as a spray solution, either method accompanied by scrupulous cleanliness in cultivation and the destruction of diseased stock.

The net result of Ogilvie's researches and the application of appropriate measures of control has been to reduce the "rosette" disease to what is virtually a negligible point, and as the mosaic disease which seems also to have been present has apparently been mastered, the produce of the Bermuda Lily fields may be considered free of suspicion. It remains now for buyers to do their part and as the Easter Lily is bought here mainly by the trade for the sale of the flowers in the florists' shops, the matter rests more with them than with private growers. No doubt the full resuscitation of the Bermuda Lily industry hinges mainly on the price of the bulbs, but the tendency of the day in favour of British products should have its effect in turning the scale.

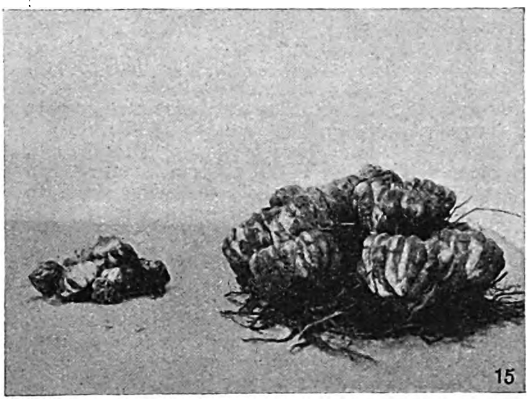

FIG. 49.—ROSETTE DISEASE OF LILIUM.
Diseased bulbs on the left; clean bulbs on the right, illustrating the effects of infection on the size of the bulbs.

Mr. Ogilvie is to be congratulated on a praiseworthy piece of research. The illustrations (Figs. 46, 47, 48 and 49) have been kindly lent by the Cambridge University Press. *A. Grove.*

JOHN INNES HORTICULTURAL INSTITUTION.

CONFERENCE ON POLYPLOIDY.

THE meeting arranged to celebrate the centenary of the Founder's birth took place at Merton, on Saturday, January 19, and was favoured with bright sunshine following a number of dull days. There was a large gathering of botanists and workers in horticulture.

Under the Chairmanship of Sir David Prain, who is Chairman of the Council of the Institution, the proceedings began with a speech by Mr. Ernest Innes, nephew of the founder. Mr. Innes described the way in which John Innes first came to own property in Merton, and the events which led up to the foundation of the Institution. John Innes was at the time in partnership with his brother, dealing in land in the City, and one day, at a sale, where they were waiting to bid for some property in town, the Merton Park Estate was put up. The auctioneer insisted that it was a great bargain, and was even willing to back his opinion with a guarantee, so in the end the brothers bought the property, neither of them having seen it or heard of it before. From this chance beginning arose John Innes' connection with the neighbourhood. At a later period he settled in Merton, built himself a house and devoted himself to developing the estate. He took a great interest in Merton, building a Freemasons' Hall and helping to found the Rutlish School. He planted trees along the new roads and took a special pride in the Holly hedges, which were clipped all around the estate by his own men, the tenants being bound not to cut them down. At his death he left considerable funds for the foundation of a School of Horticulture. His will also provided that a public park and a recreation ground should be made out of the private grounds attached to his house. Mr. Innes said that he did not think his uncle had contemplated anything of such national significance, and spoke warmly of the work that had been done to put the Institution on its present footing, especially through the high standard established by the first Director, the late Mr. William Bateson.

The scientific part of the programme was started by Mr. J. B. S. Haldane, director of the genetical work at the Institution, who gave a brief definition of the subject to be discussed. The cell-nucleus in any plant, he said, consists of a definite and characteristic number of bodies, the chromosomes—as a rule—an even number. When the plant makes gametes, that is, pollen and ovules, each gamete gets just half of the number of chromosomes characteristic of the plant. There is strong reason to think that with these chromosomes are associated most, but not all, of the characters associated with the species. But occasionally a plant appears with a number differing from that generally found in the species. For example, the ordinary Primula sinensis has twenty-four chromosomes, but the giant race has forty-eight. Here twenty-four is the diploid number (*i.e.*, twice the gametic number in the normal race), the giant race with forty-eight being tetraploid. A race with three times the diploid number would be hexaploid, and so on. In addition to these regular polyploids there are aneuploids, where the number is not a simple multiple of that found ordinarily. Mr. Haldane went on to emphasise the difference between the two classes of polyploids, viz., auto-polyploids, where all the chromosomes of the plant are derived from one species by doubling, as in giant Primula sinensis, and allo-polyploids, where half the chromosomes are derived from one species and half from another, the result of doubling in a species cross, as in Primula kewensis. Polyploids of this latter class behave more like diploids, whereas auto-polyploids behave very differently.

Mr. Haldane was followed by Dr. C. C. Hurst, of Cambridge, who gave a rapid survey of the genera of plants in which polyploidy has been found to occur, the list including Strawberries, Sugar Cane, Maize, Tomatos, Ornamental Cherries, Roses, Tulips, Hyacinths, Dahlias, Cannas, Primulas, Petunias, Ranunculus and Iceland Poppies. Many of these, he stated, are giant forms which appeal to the horticulturist, and it is therefore evident that polyploidy is a fruitful source of horticultural varieties. Dr. C. C. Hurst also affirmed his belief in the large part played by polyploidy in evolution, not only in plants but in animals, an attitude that was strongly challenged by Professor E. W. MacBride in the discussion that followed.

The next speaker was Professor R. Ruggles Gates, of King's College, London. Professor Gates, who was himself the first to report a case of polyploidy (Oenothera, in 1909), gave a historical account. He described how rapidly the subject had advanced since the first discovery, and dealt with the various theoretical views that have been put forward to account for the origin of polyploids. His views provoked a certain amount of controversy, particularly as to whether an egg-cell with the diploid number of chromosomes, instead of the usual half number, can take part successfully in fertilisation.

Mr. C. D. Darlington, of the John Innes Institution, then gave a short account of the mechanics of chromosome pairing, in the light of his recent work and that of the late Mr. W. C. F. Newton on Tulipa and Hyacinthus, after which Mr. J. B. S. Haldane, again taking Primula sinensis as his example, discussed certain difficulties which auto-polyploidy put in the way of the practical breeder. Where a "recessive" character, *i.e.*, one that only appears in the complete absence of the corresponding "dominant," will appear in one plant in four of the second generation from a cross in the diploid, the proportion in a tetraploid is only one in thirty-six; and the chance of combining two recessive characters, one to sixteen in the diploid, is in the ratio of one to over a thousand plants in the tetraploid, thus greatly increasing the difficulty of producing any desired combination. For example, a single plant of a Blue Giant Primula sinensis once turned up at a famous nursery; the nurseryman knew that if he crossed it out to anything else he would have great labour to recover it, so he contented himself with selfing the plant, which turned out to be self-sterile, and died, the blue strain being thus lost to cultivation. This, said Mr. Haldane, was why we had no blue giant Primulas to-day. A further complication arises, he explained, in the matter of linkage—in the diploid only one type of arrangement is possible, in the tetraploid one may be dealing with any one of seven different arrangements.

Dr. C. L. Huskins then described some of the work which had been done with cereals. The bread Wheats are hexaploid. The great variability in Wheat and Oats, he said, is due in part to their polyploidy. More primitive types of Wheats are known which are tetraploid and diploid, and crosses of different tetraploids have produced octoploids by doubling.

Dr. F. W. Sansome discussed and demonstrated the artificial production of polyploids—triploids and tetraploids—in Tomatos. The method is to cut back the young plants, when a certain proportion of the adventitious shoots arising from the callus are found to be polyploid. The treatment produces, on an average, one polyploid plant in fifty. This method is of great value in that polyploids can be obtained directly from diploids of known constitution and the relative behaviour of the two groups studied.

Mr. M. B. Crane discussed the effect of polyploidy on fruit production in Rubus and Prunus. In the former genus cytological work had shown, he said, that abundant fruit production was associated with the possession of an even chromosome number, the diploids, tetraploids and hexaploids being very much more productive than the triploids and other uneven forms. Thus the Loganberry, with forty-two chromosomes, a hexaploid, is much more prolific than the Laxtonberry, a heptaploid with forty-nine chromosomes. Similarly, all the triploid Cherries in cultivation are ornamental forms, grown for the flowers only and often completely sterile, the fruiting forms being all (approximately) diploid or tetraploid. Mr. Crane showed specimens of Prunus seedlings raised at Merton.

Miss Pellew gave a demonstration of the allo-polyploid Primula kewensis, the well-known fertile tetraploid hybrid between Primula floribunda and P. verticillata.

Among those present were Mrs. Bateson, Miss E. R. Saunders, Dr. A. W. Hill and Dr. O. Stapf, of Kew, Professor V. H. Blackman, Professor E. W. MacBride, Professor F. W. Oliver, Professor Dame Helen Gwynne-Vaughan, Professor J. Percival, of Reading; Professor F. L. Engledow of the Cambridge School of Agriculture; Mr. F. C. Brown, of the R.H.S. Gardens; Mr. W. Hales, of the Chelsea Physic Garden; and Professor J. S. Huxley. *Hilda Schafer, John Innes Horticultural Institution.*

MESEMBRYANTHEMUM.

(Continued from p. 34).

17.—CRYOPHYTUM, N. E. Br.

C. gibbosum, N. E. Br.—Annual, ¾–1½ inch high, with 2–3 pairs of opposite and widely-spreading branches ½–2 inches long, each bearing 1–4 flowers at the end; whole plant glabrous and papulose, with about 4 papulae in the space of a line. Branches about 1 line thick at the upper part, fleshy, tapering downwards and becoming dry and rigid below, with internodes 2–6 lines long, green or dark red. Leaves opposite, all withered on the specimens seen, 2–10 lines long, ascending or spreading, apparently terete, obtuse, dilated into a flattened sheath and scarcely united at the base, papulose, and with or without marginal cilia at the base. Flowers bracteate, sessile. Calyx-tube above its union with the ovary, ½-line long, unequally 4–5–lobed above; lobes 1¼–2¼ lines long, subulate from a dilated base, which is more or less membranous and ciliate at the margin, and with a stout and very conspicuous hump or compressed gibbosity ½–¾ line long, spreading horizontally from the base of each. Corolla apparently 3–4 lines in diameter; tube about 1¼ line long; petals about 1½ line long, white, sometimes tinted with lilac at the tips. Stamens few, 1–1½ line long. Stigmas 4–5, erect, about ½–line long. Ovary half-superior, 4–5–angled, with 4–5 cells; placentas axile.

C. nodiflorum. L. Bol. in *S. Afr. Gard.*, 1928, p. 84, f. 34, as to No. 3 only.

Piquetberg Division: Eendekuil, Maughan Brown.

The gibbosities on the back of the calyx-lobes are remarkable, and unlike anything I have yet seen in this group.

C. nanum, N. E. Br.—Annual, 1–3 inches high, branching from the base, coarsely papillate with glittering watery papillae, glabrous. Branches 1–3 inches long. Leaves opposite, petiolate, ¾–2 inches long, ½–1 inch broad, spathulate-ovate or rhomboid-ovate, acute or acuminate, flat, more or less undulated, rather abruptly narrowed below the middle into a petiole ¼–1 inch long and 2–4 lines broad, thick and fleshy, with a prominent midrib beneath, and much more coarsely papillate on the lower than on the upper surface, with the papillae ¼–½ line in diameter, green or reddish. Flowers solitary or 2–5 in a cyme, terminal. Pedicels 1 line or less long, 1¾–2 lines thick. Calyx produced above the ovary into a tube about 1 line long, sub-equally 5-lobed above, covered with large, glittering papillae ½–¾-line in diameter, ovary, part sub-globose, 3½–4 lines in diameter; lobes apparently erect, 2–3 lines long and about the same in breadth, sub-orbicular, obtusely rounded at the apex. Corolla apparently not more than 6–8 lines in diameter; petals united below into a tube 2 lines long, with the free part 1¾–2 lines long, very slenderly filiform-linear, lilac-pink at the apical part, white at the basal part. Stamens in several series, the longer about 2 lines long, creamy-white. Stigmas 4–5, erect, with recurved tips, 2 lines long, filiform, white. Ovary half-superior, 4–5-celled. Capsule half-superior, 3–3½ lines in diameter, 4–5-angled, with 4–5 raised and gaping sutures, with blackish-brown edges.

Malmesbury Division: Region of Saldanha Bay, Maughan Brown.

This species seems to be allied to the giants of the genus, C. Barkleyi, C. grandiflorum and C. grandifolium, but is very much smaller than any of them.

C. Bijliae, N. E. Br.—Annual, about 6 inches high, glabrous, papulose. Stems several from the base, erect, cymosely branching at the top, apparently somewhat angular, with internodes ½–1 inch long, 1–1⅓ line (or perhaps more when alive) thick, with distinct watery papulae. Leaves opposite on the stems, alternate on the flowering part, ½–2 inches long, 2–8 lines broad, 1 line thick, the lower more or less spathulate-ovate or spathulate-lanceolate, cuneately tapering into a petiole, the upper more or less cuneately-lanceolate or linear-lanceolate, obtuse or acute, slightly channelled above, keeled beneath, minutely papulose under a lens, green, often reddish at the edges. Flowers usually alternate and opposite a leaf along the branches of the cyme. Pedicels 2–5 lines long. Calyx acutely 5-angled on the ovary-part, somewhat unequally 5-lobed, minutely papulose; the two leafy lobes 2½–4 lines long, linear or narrowly spathulate, obtuse. Corolla only seen in withered condition, with the tube 1½-line long, and the free part of the petals 2 lines long, less than ¼-line broad, linear, obtuse, stated to be creamy white, slightly tinted with pink at the tips on the under-side. Stamens in 4–5 series, white. Stigmas 5, erect, 1 line long, filiform. Ovary half-superior, conical and 5-angled at the top, papulose, 5-celled. Capsule 2½–3 lines in diameter, when closed, 5-angled, of generic structure. Seeds less than ½-line in diameter, compressed, D-shaped, minutely tuberculate, brown.

Mossel Bay Division: near Great Brak River, Mrs. D. van der Bijl, 44.

Allied to C. Rogersii, L. Bol. and C. Wilmaniae, L. Bol., but with broader leaves, and an angular calyx, which is not nearly so coarsely papulose. *N. E. Brown.*

(To be continued).

THE YELLOW DAY LILIES IN AMERICA.*

(Concluded from p. 66).

Early-flowering Garden Varieties.

The hybrids in the group of early-flowering garden varieties are fairly numerous. More have been produced than are to be found in current nursery lists. Every effort has been made to obtain all available by purchase and through the generous gifts of several amateurs. In general terms, they fall into three groups, according as they show the predominating influence of H. Middendorffii, H. Dumortieri or H. flava. There are several others which give the appearance of the influence of some of the late-flowering species.

Apricot, one of the most charming horticultural sorts, is a hybrid long known to the trade which, by the type of inflorescence and shape of the flower, suggests its derivation from H. Middendorffii. It resembles this plant in all respects, but is larger, later, and of a paler colour. The foliage is deciduous. It spreads sparingly, but is easily divided, although there are no stolons; raised by Mr. G. Yeld.

Gold Dust, Orangeman, Flamid, and possibly Estmere, suggest crosses between H. flava and Dumortieri. All are vigorous in growth, producing dense tufts of dark green foliage with abundant overarching, somewhat branched inflorescences. The flowers resemble those of H. Dumortieri in general style, but are larger in all their parts. The leaves are deciduous, and there is no increase by stolons. Gold Dust will produce some seeds, but Orangeman is apparently sterile. The former is pale yellow with brown-stained buds; the latter is deeper orange in colour, with very little brown on the reverse. This absence of outer colouring makes a marked difference in the appearance of the clump in the garden, so that the flowers, although similar when near by, show quite differently in colour effect at a distance. The varieties Flamid and Estmere resemble these, but they are not offered in this country to the writer's knowledge. Tangerine, which was developed about the same time, is a more desirable sort and should be imported. Its chief asset is its deep-orange colour, which is not represented in any other variety flowering at this time.

---

* By B. Y. Morrison, Senior Horticulturist, U.S. Bureau of Plant Industry. Reprinted, in substance, from Circular No. 42, U.S. Department of Agriculture, Washington, U.S.A.

Sovereign and Royal are the two sorts whose buds are stained with brown as in H. Dumortieri, but whose segments are broader and smoother, suggesting more the influence of H. flava. Both are charming and desirable plants, although somewhat similar. They are slightly scented.

The remaining forms, Ajax, Aureole and Queen of May, all carry larger, heavier flowers, such as are to be found in the late-flowering group. All are intense yellow. The first and the last are the more beautiful, whereas Queen of May is the last of the three to flower.

The Meehan Day Lily, another plant of unrecorded hybrid origin, received as Hemerocallis Meehani, follows these, and reaches its peak of flowering before the late-blooming group is at its height. In general appearance it suggests H. aurantiaca major, but its flowers are paler in hue and do not show the clear base of the petals. It is moderately free-flowering, but is valuable chiefly as a possible bridge between the early and late groups.

Several new sorts, flowering between seasons and developed recently in England, have flowered in the writer's garden. Of these the variety Queen Mary is, perhaps, the most conspicuous, resembling the variety Meehan, but having rather better form. Very tall-stemmed and striking is Gold Imperial, with large, pale-yellow flowers of rather starry form. Thelma Perry flowers late in June, with lemon-yellow, Lily-shaped blooms much like the later-flowering H. citrina hybrids. More like Gold Imperial, but distinct in its trumpet shape, is the yellow-hued Yellow Hammer.

There are others that flower between these last members of the early group and encroach on the season of the summer-flowering group. The most conspicuous of these is the large and very handsome variety George Yeld, named after the originator of many of the older sorts. Its colours are a rather brilliant orange over yellow, with red-orange patches on the three inner segments.

Late-flowering Garden Varieties.

The late-flowering varieties come into bloom in two groups that overlap considerably. In July, Florham, Sir Michael Foster and luteola, with its several varieties, are the chief contributors to the garden colour, but before they are over, the derivatives of H. citrina bloom and last through August and often into September. The earlier of these two sets contains, on the whole, the more brilliant flowers, but the second group is valuable for the unusual height of the flower stalks and the fragrance of the blossoms.

Florham is a variety of American origin which forms large clumps of half-evergreen foliage from which the stalks of flowers rise to a height of four feet or more. The flowers are large and of fine form, with ruffled segment edges. They are sweetly, but not strongly, scented. Florham should be increased by division.

Sir Michael Foster is a cross between H. aurantiaca major and H. citrina and bears the largest flowers of all. They are huge, starry trumpets of delicate empire to apricot yellow. The plant is half- evergreen, produces no stolons, and is rather slow of increase.

Luteola is the name given to a hybrid of H. Thunbergii × H. aurantiaca major, while luteola major is the result of the reciprocal cross. The two plants are much alike, similar to Florham except for the deeper colour of the flowers, but perhaps a little less fine. Luteola pallens, a cross between H. citrina and H. Thunbergii, and luteola grandiflora are less happily named, for they differ from luteola far more than the names might suggest. The first is more starry in shape than either of the first two and does not reach to great a height. Luteola grandiflora is somewhat finer than the others, and the shape of the flowers suggests that of H. fulva or H. aurantiaca major, rather than the more trumpet-like luteola. But whatever the reasons for grouping, the four make excellent garden plants, especially when they are well developed.

During July also blooms the H, fulva hybrid known as Maggie Perry. It very much resembles H. fulva cypriana in colour and form and differs from the typical H. fulva only in its darker red colour and the sharply defined yellow bases of the petals. It is valuable chiefly in extending the colour range of the family in the darker hues.

While these are still in full bloom, the first flowers of ochroleuca, Baronii, Lady Fermoy Hesketh, and the unnamed hybrids of H. citrina, offered in at least one strain, commence to open.

Ochroleuca and Baronii are products of the same cross and are very similar. The first is the better of the two, with larger flowers slightly more expanded. It increases very rapidly and appears to bear transplanting better in the spring than in the fall. Both are hybrids from H. Thunbergii × H. citrina, and both are evening flowerers. Lady Fermoy Hesketh very closely resembles H. citrina itself, but opens in the morning and has rather broader perianth segments. It has a very long flowering season. The "citrina hybrids" known to the writer are all very tall plants, some being fifty inches high, with rather small, starry flowers of pale greenish-yellow. Some open in the evening and some are day flowering. All are delightfully scented, as are the other citrina hybrids. The foliage is entirely deciduous, and there are no stolons. Although there has been no published statement, certainly H. Thunbergii must gave been the other species involved. They produce a large number of flowers on a stalk and, as they commence to flower late, are valuable for continuing the season of bloom. Another plant, obtained under the name Globe d'Or, obviously belongs to this section, although the writer has been unable to obtain any history of the plant. It blooms in the evening and is of no special value, save for the lateness of its season of flowering.

Hybrids Under Trial.

There are numerous plants, some named and under trial and others not yet introduced, which will undoubtedly add to the value of this family. Dr. Stout's work has already been mentioned. Amos Perry in England has made numerous additions to the variety list; Carl Betscher has important sorts to introduce, and several amateurs are at work in this country.

As might be expected in so small a group, the improvements will have to be critically studied, and the variations that may arise in the limited range of colour, size, form and time of flowering will have to be well marked to be worthy of consideration.

Value as Garden Plants.

The writer's interest in Yellow Day Lilies developed from the use of the early-flowering sorts to supplement the yellow varieties of Iris in mixed perennial borders where the brilliance of their colours is of great value in contrast with the delicate lavenders and purples of the Irises, and their arching, grassy leaves accentuate the erect, sword-like thrust of the Iris leaves. They show as desirable contrasts with the leaves of Phlox, Funkia, Delphinium and Paeony, and make valuable additions to the foliage textures of the border.

The range of this colour, however, from pale yellow to intense reddish-orange, presents some difficulties. As suggested in *Farmer's Bulletin* 1406,* the Yellow Day Lilies should not be planted near the mauve and pinkish Iris varieties, nor near the deep-coloured Paeonies. Where they overlap the season of the early Delphiniums or any of the white flowers of the border the effect is delightful. The same conflict with mauve must be borne in mind for the season that produces both Phlox and Monarda. The whites and palest pinks of Phlox are very charming near the pale sulphur forms like H. Thunbergi and the various citrina hybrids, but the deep purplish colours in Phlox and the intense reds of Monarda work havoc with the yellows and orange of the Day Lily.

The summer-flowering forms are of the greatest value to the garden designer for their height, many of the stalks rising to more than four feet even in rather dry soils. A good-sized clump of these slender Reed-like, stems rising from the clump of arching foliage and crowned with myriads of pale-yellow, Lily-like flowers, becomes a notable feature of the summer border. Planted in large masses near shrubbery groups of Buddleias, Hibiscus and summer-flowering Hydrangeas, they make desirable features in naturalistic plantings.

THE GENUS PRIMULA.

(*Continued from p.* 66).

JAFFREYANA (King). Jaffrey's P.

(Obtusifolia.)

A smooth or slightly mealy perennial species with a tuft of thin, blunt leaves with egg-shaped blades, tapering to a short, winged stalk, in all from one to one-and-a-half inch long; margins rather sharply toothed. Flower stem two to four inches tall, bearing an umbel of six to eight pale purple blossoms. Corolla flat, nearly three-quarters-of-an-inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical below, expanded towards the mouth, about twice as long as the calyx.

This species is found in damp situations in the Chumbi valley, in the Sikkim Himalayas, at about 12,500 feet above sea-level.

Culture: Plant it in good friable loam, in a cool, half-shady spot.

JAPONICA (A. Gray). Japanese P.

(Candelabra.)

The wild type of this well-known perennial is quite free from meal, with the exception of the calyx; it produces a tuft or rosette of thin leaves, with egg-shaped, oblong, blunt blades, tapering to a winged stalk dilated at the base, in all from four to six inches long; margins sharply and irregularly toothed. Flower stem nine to twenty-four inches tall, bearing several superposed umbels of numerous purple, rarely rose or white, blossoms. Corolla one to one-and-a-quarter inch across, with flat, broadly heart-shaped, notched lobes; tube about five-eighths-of-an-inch long, dilated upwards, with a ring in the mouth. *Bot. Mag.*, t. 5916. Introduced in 1871.

Grows in damp or swampy places in the mountains of Japan, in the islands of Yesso, Hokodate and Nippon.

Culture: It delights in rich, somewhat heavy loam, in a moist shady spot; although perennial, it should be raised frequently from seeds.

JESOANA (Mig.). Yesso P.

(Cortusoides-Geranioides.)

A Japanese perennial species of no great beauty, with a tuft of membranous leaves with rounded, heart-shaped, somewhat pointed blades about two-and-a-half inches across, on slender stalks three to six inches long; margins sharply toothed and fringed with short, bristly hairs. Flower stem nine to twelve inches tall, usually bearing two superposed umbels of two to four reddish blossoms, on stalks about five-eighths-of-an-inch long. Corolla funnel-shaped, rather small, divided into five wedge-shaped or broadly heart-shaped lobes; tube cylindrical below, dilated upwards, about twice as long as the calyx. Illustrated in *Notes from the Botanic Garden, Edinburgh*, 1913.

Grows in damp, shady places in elevated localities, in the island of Yesso, Japan.

Culture: Loam and leaf-soil, and a cool, shady spot, are indicated.

---

* Morrison, B. Y. *Garden Irises.* U.S. Dept., Agr. Farmers' Bulletin, 1406, 46 pp., illus., 1926.

jonarduni (W. W. Sm.). Jonarduni's P. (Dryadifolia.)

A beautiful, minute, perennial species with a woody root-stock divided into numerous branches clothed with old and new leaves, forming mats six or more inches across. The close, crowded rosettes of fleshy leaves have nearly square blades about one-eighth-of-an-inch long, on winged stalks equalling or somewhat shorter than the blade; margins involute, with a notch on each side of the rounded tip; upper surface sparsely clothed with very short hairs, underside coated with meal. Flower stem very short, bearing a solitary, rose-crimson blossom immersed in the rosette of leaves. Corolla about five-eighths-of-an-inch across, flat, with egg-shaped, deeply notched lobes; tube cylindrical, about a quarter-of-an-inch long. Flowers in June.

Grows in dense mats on rocks and slopes in exposed situations, on Doshong La, in south-eastern Tibet, at 12,000 to 13,000 feet above sea-level.

Culture: Good, fibrous loam, peat and limestone chips, and a well-drained, open spot, with protection from damp in winter, are the conditions required.

juliae (Kusnez.). Julie's P. (Vernales.)

This richly-tinted Caucasian species is becoming a deservedly popular garden plant. It is of close, tufted or spreading habit, and produces short, stolon-like shoots from the central rootstock, these root at the nodes and give a ready means of increase. The leaves, which are numerous, are kidney-shaped or rounded, heart-shaped at the base, one-and-a-quarter inch to two inches long, on slightly winged stalks up to three inches in length; margins wavy and bluntly toothed. Flower stem obsolete. Flowers on slender stalks up to three inches long; these curve outwards from the centre of the plant. Corolla deep rosy-purple, one-and-a-quarter-inch across, divided into five oval, shallowly notched, slightly recurved lobes; tube cylindric below, narrowly funnel-shaped upwards. Flowers in March and April. *Gard. Chron.*, 1912, Vol. LI, p. 293, Fig. 142. Introduced in 1911.

Grows in shady places in the Caucasus.

Culture: The plant is not particular as to soil, but thrives best in deep loam and leaf-soil in a cool, half-shady spot. *A. W. Darnell.*

(To be continued.)

NOTICE OF BOOK.

Flowers of Kashmir.

Except that the derivation and meaning of the botanical names has been included in it, as for example, in the case of Hypopithys lanuginosa, of which the generic name is derived from *hypo*, under, and *pitys*, Pine tree, and the varietal name means woolly, the second volume of Father Blatter's enumeration of Kashmir plants* follows the lines of the first volume, which was reviewed in our issue of January 28, 1928 (Vol. LXXXIII, p. 67). As Mr. F. J. Mitchell, at whose request Father Blatter agreed to undertake the enumeration after Professor F. Hallberg's death, always wished that it should be for popular use, the concession to those whose botanical education has not gone beyond a certain point will be appreciated, and might be more generally followed in books of the same type.

As those who know the Himalayan flora would expect, the Gentian genus is well represented in this volume by no fewer that twenty-one species, as well as two others of questionable novelty. Several of these Kashmir species have baffled cultivators here, but that beautiful plant, G. Kurroo, which is possibly the pick of the Western Himalayan section, made itself happy for several years in Mr. Hiatt Baker's garden at Almondsbury, on the shore of the Bristol Channel. The species is now in cultivation again from seeds sent here by order of the Maharaja of Kashmir, and we may hope it will soon put the colours of its portrait on Plate 41 to shame, for they do not do the plant justice. Although there is no illustration in the second volume to compare with the Plate of Meconopsis aculeata which had the place of honour in the first volume, there is no lack of plates. The drawings, generally, by Mrs Wathen and Haldar Joo Walli, are more life-like than the colours, which suffer the limitations inevitable to photographic reproduction in three colours, and the figure of Gaultheria tricophylla on Plate 37 is a capital instance. Even at 13,000 feet, the fruit of this pleasant little species could hardly reflect the coerulean mantle in such brilliant fashion. On the other hand, the petal colour of the diminutive figure of Ixiolirion montanum on Plate 59 has been happily caught. The reader might be excused for rubbing his eyes on finding this Syrian plant included in a Flora of Kashmir. It is common in fields about Srinagar, and is an introduction to the country. Although the critical eye notices the omission of North America from the countries included in the geographical distribution of Moneses uniflora, errors and omissions are rare.

GARDEN MANURES FOR FEBRUARY.

In the use of manures, either natural or artificial, it is necessary to consider not only the original physical properties of the soils in question, but also the physical effect of the use of various manures on them. The physical condition of a soil is a highly important factor in plant nutrition and, although this phase of soil ethics frequently receives scant attention, it may be stated with emphasis that no system of manuring can give the highest degree of satisfaction which does not take into consideration its relationship to the physical conditions prevailing. Soils differ widely from each other in their physical properties. Some geological formations yield soils of high average fertility, while others yield inferior soils; some are wet and consequently cold, while others are dry and relatively warm; some are easily worked, others are exceedingly tough; and some are easily burnt up through drought, while others maintain a thriving herbage through the most trying conditions. Successful gardening depends on the cultivation and production of crops from all these types of soil, and it is obvious that no "cut and dried" system of manuring can be equally applicable to them all. The modern practitioner owes the modern chemist much, but it may also be stated that the complete success of the chemist's products is largely in the hands of the practitioner.

The physical nature of a soil depends on the proportion in which its proximate ingredients, sand, clay, lime, vegetable matter and mineral fragments, are present. Whatever the geological derivation of a soil, it will be found that all fertile soils are thus constituted, the quality depending, to a large extent, on the proportion in which these ingredients are mixed together.

Pure sand cannot be stated to be in any sense a plant food, but it acts as a divider or opener of the soil, facilitates the percolation of water and penetration of air, renders more easy the passage of roots in search of plant food, confers a degree of warmth on soils, first by accelerating drying, and secondly, from its inherent power of retaining warmth, and renders the soil easier of tillage; therefore it plays a very important part in the great and comprehensive work of plant nutrition. A calcareous sand simply means a sand in which particles of lime—it may be shells, or chalk—abound; many sea sands are of this nature, and besides giving the services above enumerated, also act as a source of lime.

The purest forms of clay are exceedingly plastic in character, to which property they owe their value as a material for making bricks and pottery; but this property is of equal importance in horticulture. In nature, however, clay is almost invariably associated with potash, soda, lime, ferric oxide, magnesia and carbon dioxide, and these render it more valuable as a soil constituent than if it were pure. It is partly in consequence of their presence that a clay soil is often relatively rich, and that clay ranks among the most valuable constituents of soil. It helps to maintain fertility by the introduction of valuable mineral food constituents; gives a certain consistency favourable to the retention of moisture, and favours capillarity when well worked, thus enabling a soil to resist drought.

Lime is an important constituent of all fertile soils, and besides acting as a chemical re-agent, it is in itself a plant food. It exerts a strong effect on decaying vegetable matter by accelerating its resolution into carbon-dioxide, ammonia and water; it also combines with vegetable acids and forms, with them, neutral lime-salts no longer injurious to plant life, and it has an important effect on the mineral matter of the soil by decomposing the silicates and setting free their alkalies, thus acting on both the organic and inorganic constituents of soils. Lime acts mechanically by improving the texture of clay soils, making them more friable, and, being of intermediate tenacity, it is also able to confer a higher degree of consistency on light soils.

Vegetable matter has accumulated in all cultivated soils, and although a soil may be temporarily rich without it, as proved by the fertility of lava soils, it is a highly important constituent for the maintenance of permanent fertility. It results in the formation of humus and is constantly in a state of decay or slow combustion, which is never completely arrested until it is reduced to a condition of pure carbon. Humus is not assimilated directly by plants, but it is valuable as a perpetual source of carbon-dioxide, and in a less degree, as a source of nitrogen. Its gradual decay maintains the interstitial atmosphere rich in carbon-dioxide, and impregnates the rain, which penetrates the soil, with the same ingredient. In this manner it becomes useful in the nutrition of plants and at the same time assists in that slow digestion which liberates insoluble matter from the soil and renders it fit for the use of the plant. Without it a soil would be light in colour, powdery, dry and harsh to the touch; with it, it becomes dark in colour, cool, moist and mellow, and in every way better fitted for the growth of plants.

Mineral fragments in the shape of stones, might, at first sight, appear rather as intruders than as legitimate constituents of a soil, yet they form a not unimportant component part. Their precise nature will depend on the origin of the soil; we expect to find water-worn pebbles in an alluvial deposit or drifted soil; in an oolitic limestone, irregular fragments given up from the rock beneath; and in a chalk soil, flints. They always modify the character of the land, and many soils now worked as light lands would be unworkable clays were they not divided up by countless stones. It is also important to bear in mind that these undecayed fragments are capable of yielding fresh mineral food for plants under the influence of warmth, moisture and chemical reactions. A time must come when even the largest will crumble down and we may thus regard the mineral fragments as a reserve magazine of mineral plant food. *W. Auton.*

FOREIGN CORRESPONDENCE.

COLOUR CHARTS.

Referring to the "Colour Chart" of which your correspondent, Percy E. Chappell, Major, writes in *The Gardeners' Chronicle* of December 1, he may be glad to know that we have in France a repertory of colours of a very complete kind, which is known by the name of *Oberthür's Repertory*, and is published by the Société des Chrysanthemistes and the Société Nationale d'Horticulture. I do not know whether the work is on the market. In any case, it would be easy to ascertain. *Eugène Meunissier, Ville Pamplemuosse, Avenue des Chalets, Avignon (Vse).*

HOME CORRESPONDENCE.

Gardeners' Pay and Status.—On p. 51 of your issue of January 19, your correspondent, *B. C.*, writes with a view to a possible discussion regarding the low rate of pay and equally low status obtaining in the gardening profession. I think this subject is discussed often, wherever professional gardeners meet, but, unfortunately, never gets beyond the discussion stage. It has often struck me as rather singular that, while all professions have their guilds and associations to protect their interests, we of the gardening profession have nothing of the sort really worthy of the name. I, personally, would like to see some kind of guild or association (non political) embracing the whole of the trained professional gardeners in the British Isles. *B. C.* states he has heard and seen much to discourage him; he will see and hear much to discourage him in whatever line he decides to take up, but if he has strong inclinations towards gardening, he should certainly take it up, try hard to overcome the obstacles, and leave the profession better than he found it. *J. Batty, The Gardens, Tyn-y-Coed, Llanrhos.*

Partial Soil Sterilisation.—Since my notes in *The Gardeners' Chronicle* for December 22, 1928, (p. 494), I have had several enquiries as to the best type of boiler for providing steam; and for the benefit of any one who may be desirous of purchasing a steam boiler, I would recommend the vertical type, which may be purchased second-hand from any boiler-maker, at prices to suit all requirements, but it would be necessary to make sure that the boiler chosen could be depended upon to develop pressure up to 70 lbs. per square inch. I have recently seen, in a parks department, such a boiler which is entirely satisfactory, and was supplied by Messrs. Thos. W. Ward, Ltd., Albion Works, Sheffield. This firm specialises in this type of work, and is in a position to furnish detailed particulars. I may also state that Messrs. Jones and Attwood, Ltd., of Stourbridge, have placed on the market a machine which they call the "Sterilatum," and which would possibly meet the requirements of those who are not prepared to erect a plant such as that described in my previous notes. This machine is composed of an oblong receptacle which holds several barrowloads of soil, with a space at the bottom for the water to produce steam, and a furnace underneath; it is set on three wheels so that the apparatus may be moved about conveniently. This soil steriliser was illustrated in the issue of the *Fruit Grower* for January 10, of this year. I used such a machine before I adopted the quicker method of employing a steam boiler, and am so satisfied with results, that I fully endorse the statement in the Ministry of Agriculture's leaflet, No. 209, which reads: "Soil sterilisation is no longer regarded by growers of glasshouse produce as an expensive luxury, but rather as a form of insurance and part of the year's work" (and I treat it as such), which leads me to congratulate your correspondent, Mr. L. J. Moore (p. 35), on his enterprise in constructing his own apparatus, and passing on the details of it to others. It was hardly necessary for your correspondent, John Butler (p. 35), to remind us that the subject of soil sterilisation is not new to him. There is a saying that there is nothing new under the sun, and doubtless many of your readers will remember the days when the antiquated method of sterilising a small quantity of soil for the sowing of Fern spores was conducted over the stoke-hole fire; but thanks to the energies of our scientists and big market growers, methods have been improved. Gardeners, especially, should keep abreast of the times, and because a certain method was employed twenty years ago, it is no reason why up-to-date and better methods should not be adopted. May I state that steaming as a means of partial sterilisation of the soil has become a general practice with most of the big market growers, and I fail to see how the present-day methods are at all complicated; on the other hand, gardeners who bake their soil often regret the fact that six weeks have to elapse before it can be used. Men of wide experience have told me that while baking of the soil is certainly preferable to not sterilising it at all, there is no comparison between properly steam-sterilised soil, and that which is baked; having tried all the known methods, I am convinced that the steaming method is the best, and not an expensive luxury for the few. *A. Falconer.*

VEGETABLE GARDEN.

WINTER GREENS.

It is the usual practice to dig deeply and manure fairly heavily the ground used for Brussels Sprouts and other winter greens. Thus, after a wet and frosty winter, many gaps are left in the Broccoli bed; a very great percentage of the sprouts are open, and the crops in general are not very satisfactory.

About four years ago, because a number of alterations had to be made in the grounds, the digging had not been done when the busy spring season was upon us. The Brussels Sprouts were ready for planting out, for I had sown them in February, and later they had been pricked out into a cold frame. The ground was too hard to allow putting them in with a trowel, so we planted the Brussels Sprouts with an old, worn spade, in the same way that small shrubs are planted. Previously, manure had been spread over the entire ground. Broccoli and the Kales were planted in due course, one person making a hole in the ground with a small crowbar, and another following with the plants and heeling them in well.

The result was that I had the finest crops of Brussels Sprouts and Broccoli that I had ever grown or seen. There were no open "buttons"; all were firm, and we were able to gather them up to the beginning of April. The Broccoli (both the winter and the spring varieties) turned out remarkably well, and no plants were lost.

Since then, the ground I have used for winter greens has never been dug in preparation for them. They are planted where Beans or Peas have been grown previously, after manure has been spread widely, and are earthed up when necessary. I still continue to obtain excellent crops, and the enclosed is a sample of this year's Brussels Sprouts. They are Dickson and Robinson's "Exhibition," and if there is a fault that can be found with them, it is that they are too large. *T. Bradley.*

[Judging by the sprouts received, which were of large size and in splendid condition, Mr. Bradley is an extremely successful cultivator of Brussels Sprouts.—Eds.]

THE CANSON SPROUTING BROCCOLI.

When September arrives, there is frequently a shortage of Peas, and if the weather is warm, the Cabbages and similar vegetables are not tempting. Beans should be plentiful, but Cauliflowers are not available in small gardens, therefore a new vegetable for this season is well worth a trial. The newcomer is the Canson Early-flowering Sprouting Broccoli, an autumn or late summer variety that forms a central head about three to four inches across, and after this is cut, side-shoots form smaller heads. The stems on which these heads form are very tender and stated to be almost as desirable as the heads themselves. The colour of the heads is a peculiar dull bluish-green. The flavour of this new Sprouting Broccoli is described as soft and delicate, suggesting Asparagus rather than Cabbage or Cauliflower. Messrs. Cannell and Sons, Loddon, Norfolk, the introducers, are so convinced that once this new vegetable is tried larger quantities will be required, that they are offering to send absolutely free small samples (sufficient to raise about fifty plants). A card, addressed to Messrs. Cannell and Sons, Loddon, Norfolk, asking for one of these packets, will bring the seeds and full particulars, and enable growers to test the novelty. It is stated that this new early-sprouting Broccoli is easily grown, needing about the same kind of cultivation as autumn Cabbages.

SOCIETIES.

THE ORCHID CLUB.

At the meeting of the Orchid Club, held on January 25, there was an excellent display of Cypripediums and Odontoglossums and a few fine Dendrobiums. A special feature of the Cypripediums was the large number of new hybrids, of which several received recognition from the adjudicatory Committee.

Premier Diploma.

Cypripedium Melody var. Vega.—A large flower of excellent form and colour; the orbicular dorsal sepal—three-and-a-quarter inches across—is white, with a bright green luna broken by crimson blotches, and marked in the central part by confluent crimson-purple blotches; the petals and lip are of perfect form, mahogany-red, margined with yellow.

Diplomas of Merit.

Cypripedium Maori (*C. Thisbe-Beckton* × *C. Budhoni*).—A large flower of excellent shape; the dorsal sepal somewhat square in form, three-and-a-half inches across, white, with scattered crimson-purple spots and a small green luna; the horizontal petals and well-shaped lip are green, shaded with crimson.

Cypripedium Mena (*C. Thisbe-Beckton* × *C. Chrysostom*).—A large flower, very similar in general characters to the foregoing C. Maori, but differing in the much greater breadth of the well-displayed petals. The foregoing plants were shown by Dr. Craven Moore.

Cypripedium Golden Dawn.—A medium-sized flower of a pleasing shade of green and white; the round dorsal sepal is green, with a broad band, the petals and lip are well-formed and of a soft green colour; there is an entire absence of spots. Shown by Mr. Ingham.

Cypripedium Mist o' the Moon (*C. nitens-Leeanum var. Becktoniae* × *C. Desdemona*).—A medium-sized flower of excellent shape; the dorsal sepal, oval in form, is white, the margin being slightly goffered, and marked in the centre with vertical rows of yellowish-brown spots; the petals and lip are pale green shaded with brown, and are or perfect form. Shown by Mr. A. T. Cussons.

Groups.

Sir William Thom (gr. Mr. Williams), showed a highly interesting collection of Cypripediums which included about a dozen new seedlings flowering for the first time; among these a brightly coloured form of C. Mary Thom looked promising for future distinction. The chaste C. Atholii carried a beautiful flower.

A. T. Cussons, Esq. (gr. Mr. Dalgleish), had an extensive group comprising Cypripediums and Odontoglossums in excellent cultural condition. Examples of the finest forms of C. Maudiae and C. Memoria var. F. M. Ogilvie, C. Lucifer and C. Roundhead were relieved from formality by beautiful spikes of Odontoglossum crispum and various hybrids; also worthy of note were fine examples of C. sublaeve and C. Bullenianum, a section for which Mr. Cussons professes much enthusiasm.

Dr. Craven Moore (gr. Mr. Gilden) staged a large group of highly decorative quality. Specially fine forms of white Odontoglossum crispum and O. Promerens var. xanthotes were associated with brilliantly coloured forms of Odontioda Collinge, O. Maureen, O. Marina and O. Joiceyii. The Cypripediums included large plants of C. Viking, with five flowers, and C. Corsair, with four, and C. Noel Hardy had four large yellow and white flowers, and there were excellent forms of the brilliant C. Melody, C. Makeda and C. Memoria J. H. Walker. Well-flowered plants of Dendrobium Lady Colman, D. Gatton Monarch and D. Discus completed a very pleasing exhibit.

B. J. Beckton, Esq. (gr. Mr. Stewart), exhibited a selection of high-class Cypripediums along with certain Masdevallias; of the latter a well-flowered plant M. polysticta was specially noteworthy. C. Ingham, Esq., showed some good Cypripediums, including a fine form of C. calloso-Veitchii, together with a few Odontoglossums. F. T. Paul, Esq., showed Cypripedium Perseus, C. Chrysostom var. Conyngham, and others, in excellent form.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE eighty-ninth Annual General Meeting of the subscribers to the above Charity was held at the Connaught Rooms, Great Queen Street, London, W.C., on Thursday, January 24. It was announced in the notice convening the meeting that Leonard Sutton, Esq., would take the chair, but as he was unable to be present his place was filled by Mr. Donald McDonald. Mr. E. Sherwood, Hon Treasurer, through illness, was unable to attend, but it is pleasing to record that Mr. George J. Ingram, the Secretary, was sufficiently recovered from his protracted and severe illness to be present.

Among those present at the meeting were :—Messrs. David Ingamells, Peter R. Barr, W. O. Hiehle, P. G. White, Ralph Bond, A. Dawkins, H. G. Alexander, J. Linford, A. C. Bartlett, Arthur Dye, A. Bullock, and Major E. G. Monro ; Sir Bignell Elliott was represented.

Following a short speech by the Chairman, in which he congratulated Mr. Ingram upon his recovery to good health, the Secretary read the minutes of the last Annual Meeting, and upon these being approved, presented the Annual Report, together with the statement of accounts. Extracts from the Report are appended, together with the Balance Sheet.

EXTRACTS FROM THE REPORT.

In submitting its Annual Report, together with a statement of receipts and expenditure (as audited) for the year 1928, the Committee desires to express its thankfulness that the continued liberal support it has received has enabled it to carry on the well-known work of this national horticultural charity, which has been so beneficial in affording assistance to aged and distressed gardeners, nurserymen, etc., and their widows, for the past ninety years.

At the beginning of the year there were 255 persons—men and widows—in receipt of annuities. During the year, eighteen of these have died, five of whom leaving widows, who, being eligible and in every way deserving, were placed on the funds for the widow's annuity, without election, under Rule III, 13, thus leaving at the end of the year 242 annuitants. There are now thirty-six approved candidates—twenty-three men and thirteen widows—on the list of the coming election, of whom the Committee recommend that twenty be elected this day by the votes of subscribers, which will increase the beneficiaries to 262, the largest number ever on the funds of the Institution, but, although adding to its liabilities in assisting more of those who are in such need of help, the Committee feels confident that its action will receive the approval of every well-wisher and subscriber to the Charity. Notwithstanding, there will remain sixteen candidates who must await another election before they can be placed permanently on the funds ; happily these will be given assistance from the Victorian Era Fund and the Geo. Monro Fund. During the past year, twenty persons were given grants from these two sources, while the Good Samaritan Fund gave temporary help in twenty-three cases of distress and pressing need.

The eighty-third Annual Festival Dinner, in aid of the funds, held at the Savoy Hotel on June 28 last, proved most successful.

The Committee acknowledges its great indebtedness for the services rendered by the promoters of concerts, entertainments, etc., among whom they gladly mention Mr. Charles H. Cook, of the Royal Gardens, Windsor ; Mr. Thomas H. Cook, Sandringham ; Mr. W. Auton, Woking ; the Hon. Secretaries and members of the Worcester and Liverpool Auxiliaries ; and the Altrincham and District Gardeners' Improvement Society, so well as others whose efforts on behalf of the cause have materially augmented the funds. They tender, too, their grateful thanks to His Grace the Duke of Devonshire, the Earl of Beauchamp, the Lord Northbourne, the Viscountess St. Cyres, the Lady Battersea, C. Dyson Perrins, Esq., J.P., and Roger J. Corbet, Esq., J.P., for again permitting their beautiful gardens to be opened to the public for the benefit of the funds. Very gratefully do the Committee acknowledge the valuable and appreciated services given so freely by the Hon. Secretaries and other Hon. Officers of the several Auxiliaries which continue to be a source of strength, not only financially, but in sustaining and increasing an interest in the work. From the Worcester Auxiliary alone no less a sum than £8,099 has been raised since its foundation in 1895.

It is with very deep regret the Committee has to refer to the large number of deaths among the friends and supporters of the Charity in the past year. They would especially allude to the Rt. Hon. Lord Lambourne, a Vice-President and Chairman at the seventy-seventh Anniversary Festival Dinner in 1922 ; Sir J. Agg Gardner, M.P., Sir Charles Metcalfe, Messrs. Francis Robinson (Manchester), W. H. Massie, W. H. Page, G. H. Strutt, J. Lloyd Graeme, Edwin Hiller, P. A. Ralli, Will Taylor, J. Bolton, Mrs. Leveson Gower and Mrs. Charles Edwards, who had been an annual subscriber for fifty-four years.

The Committee earnestly appeals for a continuance of the generous aid given to it in the past, so that the beneficent work which has been carried on for such a long period may be in no wise curtailed.

The Committee is very happy to be able to announce the recovery of their esteemed Secretary, Mr. George J. Ingram, from a long and severe illness which occurred immediately after the Festival Dinner, and which may be largely attributed to the strenuous work in organising and making the festival again such an entire success. Mr. McDermott, who has for many years given help in the secretarial work, has been appointed Assistant Secretary, and he, together with the Vice-Chairman, Mr. Donald McDonald, have successfully carried on the beneficent work of the Institution during the latter half of the year.

LEONARD SUTTON,
Chairman of Committee.

GEORGE J. INGRAM,
Secretary.

The Chairman, in proposing the acceptance of the Report and Balance Sheet, thanked the Committee on behalf of the meeting for the manner in which the business of the Institution had been conducted during the past year. He also spoke of the loss sustained by the Institution through the deaths of several prominent subscribers, especially the late Lord Lambourne. The Report and Balance Sheet were accepted without comment by the meeting, which then proceeded with the formal business of re-electing the Secretary, Mr. George J. Ingram ; the Hon. Treasurer, Mr. E. Sherwood, J.P. ; the Hon. Solicitors, Messrs. Ralph Bond, Veitch and Bilney, and the Auditors, Messrs. George Cobley and Co. ; the retiring members of the Committee were re-elected *en bloc*.

Major Monro, Mr. David Ingamells and Mr. Percy White were appointed Scrutineers, and the meeting then adjourned for the scrutiny of the ballot, the result of which was declared at 4.20 p.m. The successful candidates, with the number of votes secured by each, were :—Mrs. M. E. Warren, 5,956 ; Mr. R. W. King, 4,809 ; Mr. John Lambert, 4718 ; Mr. W. Slyfield, 4,262 ; Mr. J. Head, 4,135 ; Mr. J. Hall, 3,503 ; Mr. G. A. Bignell, 3,425 ; Mr. G. W. Shelton, 3,423 ; Mr. A. Bott, 3,249 ; Mr. C. Griffin, 3,031 ; Mr. G. Southcott, 2,667 ; Mr. A. J. Hancock, 2,428 ; Mr. W. Packham, 2,369 ; Mrs. Sarah J. Hale, 2,338 ; Mr. A. J. Denham, 2,223 ; Mr. J. Lane, 2,213 ; Mrs. C. J. Fletcher, 2,196 ; Mr. J. H. Marshall, 2,080 ; Mr. J. S. Davies, 2,042, and Mrs. E. Andrews, 2,014. There were 83,525 votes recorded, a reduction of about 15,000 on last year's total. The meeting granted the Theodora Kay Annuity to Mrs. Ann Davies.

Votes of thanks were accorded the scrutineers and the Chairman, and this concluded the proceedings.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION GENERAL FUND

FOR THE YEAR ENDED DECEMBER 31, 1928.

NOTE.—£1,150 will be required to meet the quarterly payments due on December 31, 1928.

The Income Tax Refund for 1927-28 has not yet been received.

WE have examined the attached accounts of Receipts and Payments with the books and vouchers, and we certify that to the best of our information they are correct.

We have also verified the investments and the bank balance of the Institution.

(Signed) GEORGE COBLEY & CO.,
Chartered Accountants (Hon. Auditors).

NATIONAL CARNATION AND PICOTEE.

THE above Society's fiftieth annual general meeting was held on January 19, at 95, Belgrave Road, Victoria, S.W. 1. (by kind permission of the London School Gardening Association). There was a large attendance of members.

The Committee's 1928 report disclosed a satisfactory state of affairs, the membership having increased during the year by seventy, and the balance in hand being over £50, as against £30 the previous year. In conjunction with the British Carnation Society, a combined exhibition was held at the R.H.S. Hall, London, on July 19 and 20, which was an outstanding success and reflected much credit upon officials and exhibitors alike. Thanks to the happy relationship existing between the two Societies, a similar combined show will be held in the R.H.S. Hall this year on July 18 and 19. Innovations in the 1929 schedule include new classes for Fancy Carnations (other than white or yellow ground) and hardy border Pinks. The best thanks of the Committee were accorded to all exhibiting members.

The retiring President, Mr. Edmund Charrington, was unanimously re-elected, and Miss Shiffner, Mr. James Fairlie and Mr. J. J. Keen (three of the Society's oldest and best-known exhibitors) were elected Vice-Presidents. Major George Churcher was appointed a Patron of the Society. The meeting regretfully accepted the resignation of the Hon. Secretary, Mr. E. G. Lowe, at the same time expressing its thanks to him for his whole-hearted efforts on the Society's behalf while holding that position. Mr. A. E. Amos was elected Hon. Secretary and Miss J. B. Wells was re-elected Hon. Assistant Secretary. The Committee vacancies were filled by the election of Messrs. S. H. Gregg, T. J. Child, E. G. Lowe, H. L. Flindt (London), and A. Reynolds (Birmingham).

ROYAL HORTICULTURAL.

January 29.—As at the previous meeting, the Horticultural Hall at Vincent Square, Westminster, was filled with exhibits of various kinds, and presented quite a gay and attractive appearance. There were several good collections of Orchids, in which long, graceful spikes of Oncidiums and Cymbidiums were prominent. The Orchid Committee recommended one Award of Merit to a novelty. The Floral Committee had fewer novelties than usual, and recommended only two Awards of Merit. The chief features of the various groups were greenhouse Cyclamens of considerable merit, a large and attractive group of spring bulbs, greenhouse Carnations, forced flowering shrubs and early border flowers. There were the exhibits of garden sundries and paintings customary at this season. Several seedling Apples were submitted to the Fruit and Vegetable Committee, but none was considered superior to the standard varieties. The only fruit exhibit in the hall was a collection of Apples from the Reading University Gardens, which was excellent from every point of view.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Frederick Hanbury, Mr. Lionel de Rothschild, Mr. Stuart H. Low, Mr. J. Wilson Potter, Mr. E. R. Ashton, Mr. A. Dye, Mr. H. G. Alexander, Mr. Fred. K. Sander, Mr. J. E. Shill, Mr. T. W. Taylor, Mr. Charles H. Curtis, Mr. J. Cowan, Mr. A. McBean and Mr. T. Armstrong.

Award of Merit.

Odontoglossum mirum aureum (*O. crispum* × *O. Wilckeanum*).—A beautiful Odontoglossum of soft yellow colouring, with a few brown markings. The flowers are of excellent form and good size, and admirably placed on a graceful spike. Shown by Messrs. J. and A. McBean.

Cultural Commendation.

To Mr. R. Cottam, gardener to G. Mayer, Esq., Wistler's Wood, Woldingham, for Cypripedium Leeanum var. Clinkaberryanum, carrying about thirty blooms.

To Messrs. Sanders, for a very fine plant of Oncidium Cavendishianum.

Groups.

Odontoglossums and Cymbidiums figured largely in the group set up by Messrs. J. and A. McBean, but the display lacked that groundwork and finish that generally characterises the Cooksbridge exhibits. A few of the leading subjects were Cymbidium Albania, C. Coningsbyanum, C. Carol, Epiphronitis Veitchii, Cattleya Tityus, Odontoglossum Cumbe, O. Adula, O. Rosina, Odontioda Bradshawiae, and Brasso-Laelio-Cattleya Cissie, of salmon-pink colour.

Messrs. Sanders contributed a fine group wherein their numerous examples of Oncidium splendidum were conspicuously good, while a big plant of O. Cavendishianum with a large, branching spike, arrested attention. Other good things included were Cymbidium rosefieldense, St. Alban's var., C. Erica Sander, good forms of Lycaste Skinneri, Calanthe Butterfly, Laelia autumnalis, Vanda Amesiana and Cypripedium Perseus.

A glorious spike of Odontoglossum crispum carrying eighteen lovely flowers of fine form, was the central feature of an exhibit staged by Messrs. Charlesworth and Co. Around this were grouped Oncidium anthocene—now rarely seen, the interesting Cattleya Percivaliana var. Charlesworthii, Odontoglossum Muralis var. rubens, of fine colour, and such good Cypripediums as C. Senator, C. Major Hanbury Carlile, and C. Halwellyn, with Miltonia Belyta.

A small group from Messrs. Stuart Low and Co. contained the brilliant Sophro-Laelio-Cattleya Beta, Cypripedium Maudiae, Cymbidium Joan, Masdevallia tovarensis, Odontioda Wilsonii, and the quaint Rodriguezia crispa. Mr. J. Evans showed some excellent Cypripediums, a few of the finest being C. aureola, C. Aleivanna var. Perfection, and C. Makeda var. Matador—of fine colour. A few Odontoglossums and Cymbidiums were included in this group.

Mr. Harry Dixon showed Dendrobium aureum, Cypripedium Roger Sander, Odontoglossum amabile and Cymbidiums.

Cymbidium Lucaste, Old Quarry var., pale yellowish-green, was shown by W. J. Burston, Esq., Haywards Heath; this is the result of a cross between C. grandiflorum and C. Warbler. The fine Cypripedium Renown, Dell Park var., exhibited by Baron Bruno Schröder, Dell Park, Englefield Green, was greatly admired.

Large plants of such old favourites as Calanthe William Murray and C. Veitchii, Cypripedium Ashburtoni, C. Lathamianum, and C. Leeanum, were shown by Lady Hadden (gr. Mr. O. Hayles), Rossway, Berkhamsted, and all were freely flowered.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. Arthur Turner, Mr. A. E. Vasey, Mr. C. F. Langdon, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. M. C. Allwood, Mr. R. Findlay, Mr. Hugh Dickson, Mr. B. C. Long, Mr. James B. Riding, Mr. D. B. Crane, Mr. W. B. Gingell, Major George Churcher, Mrs. Helen Lindsay Smith, Mr. Charles E. Pearson, Mr. G. W. Leak, Mr. Courtney Page, Mr. E. R. Janes, Mr. J. F. Smith (visitor) and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Gerald W. E. Loder (in the chair), Mr. W. J. Bean, Mr. G. Reuthe, Mr. F. G. Preston, Lady Beatrix Stanley, Mr. E. H. Wilding, Mr. C. Williams, Mr. Amos Perry, Mr. G. Yeld, Mr. A. Bedford, Mr. E. A. Bowles, Mr. L. R. Russell, Mr. W. G. Baker, Sir William Lawrence, Bt., Mr. Mark Fenwick, Mr. W. B. Cranfield, Mr. Charles T. Musgrave, Mr. R. C. Notcutt, Mr. R. W. Wallace and Mr. N. K. Gould, Secretary.

Awards of Merit.

Anthurium Rothschildianum var. Excelsior.—Nearly fifty years ago, on May 11, 1880, to be exact, the Floral Committee of the R.H.S gave an Award of Merit to Anthurium Scherzerianum Rothschildianum, which was described and illustrated in *The Gardeners' Chronicle* four days later. Anthurium Rothschildianum was raised by Mr. F. G. Bergman, gardener to Baron Rothschild, at Ferrieres; the spathe is decidedly larger than that of A. Scherzerianum, and is creamy-white, spotted with red. The spadix is usually yellow, although at times it is tinted with orange colour. The variety Excelsior has the general characteristics of A. Rothschildianum, but the spathe is much larger, more rounded, and the spadix is tinted with reddish-orange, and the brick-red markings are not so regular as in the illustration referred to above. Shown by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Southampton.

Carnation Kathleen.—This deliciously scented greenhouse Carnation is recommended for cutting and for market purposes. It is a medium-sized flower of good form, free-flowering habit, and of bright rose-pink colour. Shown by Messrs. Stuart Low and Co.

Groups.

A particularly good and extensive collection of greenhouse Cyclamens was tastefully arranged by Messrs. Blackmore and Langdon. A whole length of tabling, just inside the entrance, was filled, and not only did the many plants illustrate excellent cultivation, but most of the flowers retained the charm of the true Cyclamen shape. The principal varieties were Brilliant, Daybreak, Bath Pink, Giant White, Salmon King and Scarlet King.

At the end of the hall, Messrs. Sutton and Sons had a fascinating exhibit of spring bulbs. Mossy mounds were crowned with various Daffodils and Iris tingitana and on the sides were Hyacinths, Tulips, Freesias and Jonquils. The chief varieties which were employed in this attractive exhibit were Narcissus Golden Spur, N. Henry Irving, N. Soliel d'Or, Giant Campernelle Jonquils, and white Roman Hyacinths.

Large well-flowered bushes of Mimosas were associated with Camellias, Azaleas and Ericas by Messrs. Stuart Low and Co., who also had a good collection of Carnations which included Lady Daresbury, a well-formed flower of soft pink colour, Thomas Ives, Eileen Low and Philip Sassoon. In their collection of Carnations, Messrs. Allwood Bros. had stands of Wivelsfield Buttercup, Rapture, silvery-pink, and Guy Allwood, soft pink, among many of the older sorts, and also showed a few bowls of Dianthus Allwoodii varieties. Messrs. C. Engelmann, Ltd., had good vases of Master Michael Stoop, Laddie, Mab and Blanche in their exhibit of Carnations.

An attractive planting of early spring flowers, arranged by Messrs. Barr and Sons, included Narcissus minimus, Muscari azurea, Eranthis cilicicus, many early Crocuses, and dwarf Irises. The exhibit was framed with golden sprays of Eleagnus pungens aurea alternated with Rosemary. Messrs. Tuckers had Primula Winteri and P. Juliana in flower, and Saxifraga Paulinae, S. Burseriana major and other Saxifrages in bud. A goodly batch of Primula Barrowby Gem was shown with shapely little bushes of Irish Juniper by Mr. Stephen Sims.

In a well arranged rock garden, Messrs. William Cutbush and Son planted generous breadths of Iris reticulata, Iris sind-pers, Daphne Mezereum rubra, and a few early alpines. On higher levels, they had floriferous bushes of Chimonanthus fragrans, Garrya elliptica and Forsythia spectabilis. In a low planting on the tabling, Messrs. Wm. Wood and Son planted Erica carnea var. King George, various Crocuses, Anemone blanda coerulea, Iris unguicularis coerulea, Saxifraga Jenkinsae and Primula Barrowby Gem.

Messrs. Waterer, Sons and Crisp had a splendid bush of Forsythia spectabilis among dwarf Conifers as a background to Iris Tauri, Iris sind-pers, Iris reticulata, Crocus Sieberi, Crocus biflorus Weldenii alba and other early flowers. Goodly bushes of Magnolia Soulangiana, Forsythia suspensa and Skimmia japonica were shown by Messrs. L. R. Russell, Ltd., who again staged good plants of Epiphyllum Makoyana. Messrs. Patrick's had many dwarf Conifers, suitable for the rock garden, including Cupressus filifera nana aurea, C. plumosa aurea and C. pisifera aurea, of good golden colour. The Orpington Nurseries staged Hamamelis mollis, various Conifers, Erica darleyensis and Garrya elliptica.

In a rock garden exhibit, Mr. George E. P. Wood planted dwarf Conifers, Crocuses, Primroses and dwarf Irises. Mr. G. Reuthe had several Rhododendrons with large, luxuriant foliage, various uncommon Conifers, Ericas, Camellias and Acacias. Mr. J. Klinkert again showed shapely topiary specimens in evergreen Box.

Among the numerous exhibitors of paintings of flowers and gardens were Mrs. M. Townsend, Miss Edith Andrews, Miss W. M. A. Brooke, Miss M. Broom, Miss E. Warrington, Mrs. H. Spencer, Miss A. F. Wilkinson, Miss E. Kirkpatrick, Mrs. E. S. Ough, Miss Winifred Walker and Miss G. E. Bayley; perhaps the most interesting collection in this section was that representing flowers from southern Tanganyika, by Miss Orpen, paintings of a large variety of plants being displayed. Exhibits of garden designs were shown by Mr. Percy S. Cane and Messrs. Bakers.

As might be expected, there were numerous exhibits of garden implements and sundries, among the most interesting being the collection of ornaments by Messrs. Burton Holt, Ltd., garden baskets, etc., from the Lord Roberts Memorial Workshop; a small glasshouse by Messrs. Boulton and Paul, Ltd.; ornamental gates, etc., by the Battle Steel Window Co., and a summer-house and garden seats by Mr. C. White.

Fruit and Vegetable Committee.

Present: Mr. Joseph Cheal (in the chair), Mr. G. F. Tinley, Mr. A. Bullock, Mr. J. Wilson, Mr. F. Jordan, Mr. A. Poupart, Mr. W. H. Divers, Mr. E. A. Bunyard and Mr. A. N. Rawes, Secretary.

Several seedling Apples were shown before this Committee, but none was considered sufficiently distinct to deserve recognition.

Groups.

There was only one exhibit of fruits staged at this meeting, and this was a magnificent collection of Apples from the University of Reading Horticultural Department, which, from an educational view-point, was well worth close inspection, for there were nearly sixty varieties represented. The fruits were all richly coloured, and for so late in the season, the majority were in splendid condition. At the back of the exhibit were single-layer market trays containing fine fruits of Newton Wonder, Worcester Pearmain, Cox's Orange Pippin and King's Acre Pippin; there were large baskets of Golden Noble, Belle du Pontoise, Edward VII, Annie Elizabeth, Encore, Lane's Prince Albert and Beauty of Stoke, among culinary sorts, and Prince Edward, Fameuse, Blenheim Pippin and Reinette du Canada, good dessert varieties. Other Apples which were exceptionally well represented included Peasgood's Nonsuch, Charles Ross, Tyler's Kernel, Bowhill Pippin, Ribston Pippin, D'Arcy Spice, Barnack Beauty, Royal Late, Lord Burghley, Allington Pippin, Washington and Rival. A magnificent and well set-up collection.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall, on Monday, January 14, Mr. Charles H. Curtis presiding. Fourteen new members were elected.

Ten members withdrew interest from their deposit accounts, which amounted to £39 18s. 10d., and five members over the age of seventy years withdrew the sum of £206 15s. 2d. from their deposit accounts. The sum of £282 17s. 6d. was passed for payment to the nominees of six deceased members. The sick pay for the month on the private side was £101 13s. 4d.; state section £88 16s. 10d.; and maternity claims amounted to £9 10s. 0d. Grants were made to eight members on the state section for dental and optical treatment, which amounted to £36 17s. 6d., and six other cases were considered.

DUBLIN NATURALISTS'.

The Annual General Meeting of the Dublin Naturalists' Field Club was held at the Royal Irish Academy, on January 17. The annual report showed an advance in membership of thirteen, making a total of ninety. The Treasurer's report showed the Club to be in a satisfactory financial position, total receipts being £17 15s. 11d., and expenditure, £15 9s. 8d.

The new President, Professor M. J. Gorman, A.R.C.S., delivered an address on "Grass." Pointing out the importance of the Gramineae, he stated that there were upwards of three thousand species; in Ireland alone seventy to eighty distinct species are to be found, not taking into account the sub-species. In all temperate regions about a fourteenth of the total flora consists of grasses, which are found at all levels, from the water's edge to the summit of the highest mountain. When it is considered that a quarter of the earth's surface is covered with treeless, grassy plains, and the extraordinary range and variety of form displayed, from the tiny blade struggling on a well-kept garden walk, through the cereals, Pampas, African Reeds, and Sugar, to the giant Bamboos, the exalted position of the family is realised. From the economic standpoint, the grass family is obviously of the utmost importance. "All flesh is Grass"—it is instructive to reflect how this great universe, in an age of mechanism, is entirely dependent upon but one of the provisions of nature.

The folding of the leaves of various grasses was referred to by Professor Gorman as generally due to dry conditions, but he pointed out that it not infrequently occurs even although there be adequate water at the roots, owing to physiological dryness, a condition most often met with on mountains. There is a general tendency to regard the ligule at the base of the leaf-blade as an adaptation to prevent water from running down; it is an easy explanation, and one readily assumed or believed, but, alas! there is nothing to prove that it is so.

Professor Gorman stated that over vast areas grass forms the chief vegetation, especially where soil is rich but rainfall not distributed and there is intense heat in summer with long and severe winters—with the temperature low, the nights cold and the evaporating power of the air high; these conditions do not favour the development of tree or shrub growth, so in all such regions grass is dominant. A number of good lantern slides were shown illustrative of the use of grass in sand fixation, and of its growth, development and internal structure.

A vote of thanks, proposed by Mr. A. W. Stelfox and seconded by Mr. C. B. Moffat, was aptly conveyed to the lecturer on behalf of the meeting by Dr. R. Lloyd Praeger.

READING GARDENERS'.

"Teaching Gardening" was the subject of a lecture by Mr. John Ettle, a representative of the Bristol Gardeners' Association, before a good attendance of members of this Association, at the meeting presided over by Mr. W. Broomfield, on January 21, in the Abbey Hall. Mr. Ettle's lecture was divided under various headings, and he dealt with such subjects as the teachers, the students, elementary and secondary school gardens, horticultural colleges, flower shows and exhibitions and allotment competitions; he considered that the best training for a gardener was that obtainable in a good private garden.

The competition for the evening was for one Cyclamen plant in a pot, and some lovely specimens were shown. The first prize was awarded to Mr. A. H. Dow, The Gardens, Suthamstead House, Theale; second, Mr. J. Wynn, The Gardens, Hammonds, Checkenden; and third, Mr. A. W. Gower, The Gardens, Calcot Grange.

Obituary.

Gledhill Cottam.—Many readers will regret to hear of the death of this fine old Yorkshire gardener, after a long and painful illness, and more so as his injury was caused many years ago while staging one of the pillar groups at the York Chrysanthemum Show, which were then a feature of the exhibition. He was the winner of hundreds of prizes, and was an expert in grouping, for which he won numerous cups and medals. His services as a judge were in great demand throughout the East and West Ridings of Yorkshire. He died on New Year's Day, and leaves an invalid widow, three sons and a daughter. His second son, Mr. R. Cottam, who has charge of the Wistler's Wood gardens, Woldingham, Surrey, is the only son carrying on the family tradition of gardeners.

Frank Evans.—By the death, which has occurred somewhat suddenly, of Mr. Frank Evans, of Southfold Terrace, Birkenshaw, the district has sustained the loss not only of an interesting personality, but also of one who in a quiet way has done much useful public work. A native of Bourton on-the-Water, Gloucestershire, he devoted himself to gardening as a young man, and was sent by the firm of Messrs. J. Backhouse and Son, Ltd., of York and Leeds, to work at Gledhow. Then he removed to Birkenshaw, to take up a similar appointment at Moorlands Hall, which he held for about forty-seven years, retiring about five years ago. Among the gifts from the Oddy family which he treasured was a silver tea service presented to him when he completed twenty-five years' service, and a case of cutlery which he received on attaining the age of seventy years. He took considerable interest in the work of the allotment holders' associations, and was always ready to give amateurs the benefit of his extensive knowledge and long experience. Having for many years cultivated an allotment himself, he was brought into close contact with the local plot-holders. He was also an enthusiastic co-operator, serving on the Committee of the Birkenshaw Co-operative Society for many years, and was President of the Society.

Joseph Gérome.—We learn from the French horticultural press of the regretted death of M. Joseph Gérome, who passed away in his native place, Hadol (Vosges), on December 31, 1928, at the age of sixty-five years. M. Gérome was a professor of botany and horticulture, and had occupied successively the posts of head of the botanical school, head of the hot-houses, head gardener, and Vice-Director of the experimental garden of the Museum in Paris; and for thirty years he had delivered, each year, the course of lectures on indoor and outdoor floriculture at the Versailles Horticultural College. His studies on the origin of certain vegetables, on nomenclature, and on vegetable teratology were well-known, and he was awarded the ranks of Commandeur du Mérite Agricole, Officier de l'Instruction Publique, and, only a few months before his death, Chevalier de la Légion d'Honneur.

Johannes Gabriel.—To the Berlin Horticultural journal *Die Gartenwelt* we owe the sad news of the death of one of the most promising of the younger school of German garden "technicians"—Johannes Gabriel, "Oberinspektor" of the parks and gardens department of Essen. The young man—for he was only thirty-two years of age—had been appointed by the municipal authorities to his responsible post in view of the valuable experience he had gained in connection with the organisation of the Dresden Horticultural Exhibition. A similar exhibition is to be held shortly in Essen, and Herr Gabriel was to have had charge of the arrangements. His death will be a sad blow to the authorities, and seems a tragic end to a life full of hope and promise.

Romain de Smet.—We learn with great regret of the death, at the age of seventy-eight years, of M. Romain de Smet, brother of the late Arthur de Smet, and like him, a famous and successful Belgian horticulturist. He was one of the oldest nurserymen in the Ghent district, and had contributed in great measure to the development of the industry. His death will be a sad loss to Belgian horticulture in general, as well as to his bereaved family.

ANSWERS TO CORRESPONDENTS.

Arum Rot.—*C. P. G.* Your Arums are attacked by soft-rot, due to a Bacillus (B. carotovorus); the disease usually shows itself about January. Remedial measures include: (1) After the plants dry off, shake the "corms" free from all soil, scrape off the adventitious roots, and scrub with water, using a stiff brush; steep the "corms" in a two per cent. formalin solution (forty per cent. formaldehyde), and pot them into sterilised soil and pots; (2) cut off diseased portions from affected "corms" before treatment; (3) spray the staging and borders with a two per cent. solution of cresylic acid or Voss's Creol, before replacing the plants.

Coleus Diseased.—*T. J. M.* The Coleus plant received was attacked by one of the damping-off fungi, Phytophthora cryptogaea. Remove and burn affected plants; sterilise the soil and pots in which affected plants have been grown (180°F. for three hours); the presence of lime in the compost is a deterrent; and careful watering is essential—water should not be obtained from a contaminated source, *i.e.*, avoid using water from a tank in the house where the drainage water from the pots in which diseased Coleus are growing drips into the tank.

Names of Fruits.—*A. E. K.* Uvedale's St. Germain.—*W. F. B.* Pear No. 1, Glou Morceau; 2, Knight's Monarch; Apple Schoolmaster.—*H. L. D.* Calville Malingre.

The Dutch Elm Disease.

SINCE attention was first drawn in our columns on February 19, 1927, to the Dutch Elm Disease, by Dr. Malcolm Wilson, of the Mycological Department, University of Edinburgh, it has not only obtained a foothold in this country, but has spread with such remarkable rapidity as to make it probable that the disease was established here before its presence was detected in July, 1927, on a tree at Totteridge. The Forestry Commission has now issued a leaflet* on the disease, from which it is clear that science is as yet in the dark as to its cause and remedy. A peculiar feature of the disease, which has assumed an epidemic form in the south and centre of England, is that it has apparently made no headway in the north of the country, and this may possibly afford mycologists a channel for investigation. On the other hand, the disease seems to have been observed so far north as Norway, so long ago as 1920, and was reported at Oslo in the same year; therefore, latitude may have no bearing on its incidence. In the first stages of the disease it was thought that some species of Elm were more resistant than others, but the theory is discounted by the Commissioners, who report that all species of Elm at present cultivated in western Europe appear to be susceptible. It is certainly the case that in the south of England the Wych Elm is as susceptible as the common Elm. Although it is as yet early to reach a definite conclusion on the point, the Commissioners regard the disease as one to which immature trees are more liable than those of established age; but observation of trees in Holland shows that old specimens are by no means immune. The means by which the fungus first reached this country remain a mystery, and the leaflet makes it clear that the precise method of infection is still unknown. It may even enter by the roots. Since, however, the spores of the fungus are enveloped in a mucilaginous substance, it seems more likely that they are conveyed from tree to tree by birds or winged insects, than by wind. The suggestion receives weight from the fact that spores of the fungus have been found on insects crawling over diseased Elm stumps here. Unfortunately, it has not been possible to catch any migratory birds in the act of alighting here with the sticky spore envelope on their claws. The Commissioners are unable to suggest effective methods of control, and in view of the well-known mechanical difficulties of spraying trees forty to sixty feet in height, they wisely refrain from any suggestions on the subject. In the present state of our knowledge, it seems that the axe or the saw is the only remedy, the former to be applied in serious cases in felling the trees, and the latter in lopping isolated branches which show signs of infection. In Holland this has been done with excellent results in the case of some old trees which have shown signs of local, as distinct from general infection, but it by no means follows that the removal of a diseased bough will save a tree. On the other hand, this may save it, for it no longer seems to be considered that once a tree is infected it is definitely doomed. It almost seems as if the epidemic had some of the characteristics of a virus disease, as the trunk, boughs and branches of a tree may show the typical rings of brown spots just under the bark long before there is any external sign of anything being wrong. According to the leaflet, the fungus, Graphium ulmi, lives in the discoloured vessels of the wood, and may form fructifications on the exposed surface of dead wood. A fructification takes the shape of a minute black stalk, about 1 mm. long, which has at its apex a drop of mucilage containing myriads of microscopic spores. The gummy fructifications appear on the ends of dead twigs or on stumps of diseased trees which have been cut down, and in cracks in the stumps. The Commissioners express a hope that some species or variety of Elm may be found which is immune from infection, and meanwhile, those who contemplate the planting of Elms would doubtless be wise to hold their hands until the epidemic has passed or science has found a remedy for it. The fact that mycologists have so far been able to reach no definite conclusion as to the origin of the fungus or the means by which it is transmitted, is disappointing, for although English scientists have had but a short time in which to carry out their investigations, Continental mycologists have been working on the disease for many years. A prime difficulty is that the activities of the fungus in the field can only be studied during six months of the year.

Dahlias in Public Parks.—At the meeting of the Association of Parks and Botanic Gardens Superintendents, to be held in the R.H.S. Lecture Hall, Westminster, on Tuesday, February 12, an address will be given by Mr. A. J. Cobb (Lecturer in Horticulture, University of Reading), whose subject will be "Dahlias as a Feature in Public Parks." The address will commence at 7 p.m., and will be illustrated by lantern slides.

Venidium fastuosum.—We have received so many enquiries concerning the subject of last week's coloured plate that we cannot reply to them separately. This handsome Composite is not yet in commerce, but we expect it will be offered next year.

Ursinia anethoides—Mr. T. Hay points out that a clerical error appears in his notes on "Annual Flowers" (p. 76). The R.H.S. Award of Merit was granted to Ursinia anethoides (see *Gard. Chron.*, July 7, 1928, p. 3, Fig. 1), a first-class plant which is different altogether from U. anthemoides, the latter being not nearly so fine a subject as U. anethoides.

A Swedish Rosarian Botanist.—Immediately after the tragic death, in a little Canadian hotel, of the Swedish botanist, the Rev. Enander, an authority on Salix, and on the same day when the latter was interred at his northern home parish of Lillherrdal, two members of the Riksdag introduced a motion in the first and second chambers requesting an appropriation for engaging a *locum tenens* for the Rev. L. P. R. Matsson, in the country parish of Helsingtuna, in order to enable this clergyman to devote his time to his researches on the different species of European Roses, in which field he is regarded as a foremost living authority. He is fifty-nine years old, and has studied the wild and cultivated European Roses for nearly forty years. Leading Swedish botanists warmly support the Riksdag motion, stating that there is no one else in the world capable of following up and completing the Rev. L. P. Matsson's researches, most of which have been carried on in his private Rose garden.

Wart Disease of Potatos.—The Department of Agriculture for Scotland has issued a general licence authorising occupiers of holdings not exceeding half-an-acre in extent, and of private gardens, to plant the undernoted varieties of early Potatos, which are not immune to Wart disease, on condition that the crops will be lifted not later than August 15, except north of Angus and Perth, where the period is extended to August 31, viz.: Beauty of Hebron, Duke of York (Midlothian Early), Early Rose, Eclipse (Sir John Llewellyn), Epicure, Harbinger, May Queen, Myatt's Ashleaf, Ninetyfold, Puritan, Sharpe's Express and Victor. This licence does not apply to any land on which Wart disease has occurred, or to any land within certain districts, including Aberdeen (the Elmfield Allotments), Edinburgh, Glasgow, Perth, and a number of other delimited areas.

Proposed Society of Garden Architects.—All who are interested in the subject are invited to attend a meeting that will take place at 9, Gower Street, Bedford Square, W.C.1, on Wednesday, February 20, at 7 p.m., to discuss the formation of a proposed Society of Garden Architects. All those desirous of receiving an invitation should write to the convener, Mr. Richard Sudell, at the above address, enclosing a stamped and addressed envelope.

Queen's Institute of District Nursing.—The Gardens Committee of the Queen's Institute of District Nursing states, in its report for 1928, that 727 gardens were opened to the public between the months of April and September, and a total sum of £6,806 11s. 8d. was raised on behalf of the Institute. Of this sum, the Royal Gardens at Sandringham were responsible for £728 4s. 0d. The owners of gardens are to be invited to open them annually in support of the Institute; many owners have already agreed to do so this year.

Collecting Pollen for Treatment of Hay Fever.—It is a well-known fact that the pollen of certain flowers, and especially of grasses, is responsible for the disease known as hay fever, from which many individuals suffer annually. Recently, several scientists, working with the pollen of various grasses, have obtained good results in the treatment of hay fever with different protein fractions obtained from the pollen responsible for the complaint, and experiments have demonstrated that hay fever can be treated successfully by using extracts prepared from the particular pollen to which the sufferer is sensitive. Consequently, there is now an increasing demand for wind-borne pollen for the preparation of these extracts, and the work of collecting the pollen is considered of such national importance in America that a special pamphlet, entitled "Methods of Collecting and Preserving Pollen for Use in the Treatment of Hay Fever," compiled by James W. Kelly, has been issued by the United States Department of Agriculture (Circular No. 46, October, 1928). In this the various methods of collecting the pollen are described, and it is obvious that, in order to obtain pollen in quantity and of suitable purity, considerable skill is necessary in carrying out this work. The author describes in detail, with the aid of several instructive illustrations, the method that has so far proved most successful, and he also discusses the question of the yield of pollen from various plants, and the period at which pollenation takes place. Appended to the work is a list of the plants from which pollen has been collected by Mr. Kelly, together with the period at which the pollen of each species was collected; among these plants are Acer Negundo, Agrostis palustris, Alnus rugosus, Ambrosia elatior and A. trifida (the Small and Giant Ragweeds respectively), various Andropogons, Cannabis sativa (Hemp), Castaneas, Chenopodium album and C. ambrosoides, Dactylis glomerata, Ginkgo biloba, Helianthus annuus, Juglans nigra, Liquidambar styraciflua, Lolium multiflorum, Phleum pratense (Timothy Grass), Pinus sylvestris, Plantagos, Plantanus occidentalis, Poa compressa and P. pratensis, Quercus alba and Q. velutina, Rumex, Sambucus canadensis, Secale cereale (Rye), Tilia americana and Zea Mays.

---

* *The Dutch Elm Disease (Graphium ulmi, Schwartz).* Leaflet No. 19. Forestry Commission, London, S.W. 1. December, 1928.

"The Story of the Scottish Forests."—This was the subject of a delightful and interesting address given by Dr. James Ritchie, Natural History Department of the Royal Scottish Museum, Edinburgh, to the members of the Aberdeen Natural History and Antiquarian Society, in Aberdeen University Buildings, on January 24. Mr. J. B. Nicol, ex-President of the Society, presided. At the outset, Dr. Ritchie reminded his hearers that no subject was more closely bound up with the story of the country's development than the history of the Scottish forests. Forests had always held the fancy and inspired the awe of primitive man. In early European civilisation the forests were the great barriers which separated people from people, and for centuries prevented that intercourse of trade which, in the end, led to the diffusion of civilisation throughout the continent. One could quite easily understand how the darkness of the forests, their silence, their vastness, had all impressed themselves upon the minds of the human race. The earliest forests had long since disappeared from the surface of Scotland, and their remains lie hidden in the layers of peat bogs. But these layers tell a wonderful story of changes which pursued each other over the land 20,000 years ago. The first forest was a scanty woodland of Birch and Willow which invaded the country after the snows of the Ice Age had melted, and which clung to the valleys and lower levels of the mountain sides. The second forest was the greatest forest Scotland had ever seen. It was a vast extent of Pine which overspread the land and ascended the mountains far beyond the limit of present-day Pine woods. This great forest had long since been swamped by the bogs of a climate even moister than that of modern times; but it was succeeded by woods scarcely less extensive, which were utilised by the men of the Bronze and Iron Ages. Soon, however, the destructiveness of man began to tell upon the forests. The records of Scottish laws revealed continuous efforts to protect existing woods and to encourage fresh planting. In illustration of these laws, Dr. Ritchie raised a hearty laugh by reading quotations from these old Scottish forest rules, which contained many curious and severe penalties, even to "hanging to the death," meted out to offenders. Then Dr. Ritchie put the query: "What brought about the disappearance of these forests?" He answered it by describing how enemies had levelled the woods during times of invasion, and how the Scots themselves had burned them to get rid of the strongholds of robbers and wolves. But the lecturer attributed the greatest destruction to the use of wood for household fires, for house construction, and for the wants of the great industries. Nevertheless, he contended that man could not be held responsible for all the destruction. Changes of climate, great wind storms, forest fires and encroachments by the sea, had all played their parts in the disappearance of those superb forest lands. It was a most instructive evening, and warm and hearty were the thanks awarded Dr. Ritchie for his fine contribution to the Society's activities.

Mr. A. E. Amos.—Recently appointed Hon. Secretary of the National Carnation and Picotee Society, Mr. A. E. Amos must now be an unusually busy man, as he also holds the position of Hon. Secretary of the British Gladiolus Society, of which progressive body he was one of the founders. For about a score of years Mr. Amos has been associated with Messrs. D. Prior and Son, Ltd., of Colchester, and is now Secretary of the Company. Keenly interested in Dahlias, Carnations and Gladioli, he has won numerous awards for flowers of his own raising, including the Foremarke Cup for Gladioli in 1927, after being "runner-up" for it in the previous year. Mr. Amos is a frequent contributor to the horticultural press, and a lecturer on entomological matters; he has won several cups and medals for his entomological exhibits. From August, 1914, to February, 1919, Mr. Amos served with His Majesty's Forces overseas—Gallipoli, Palestine, Greece, etc., and it is probable that this experience created a modest "wanderlust," as we have met him in many continental cities on the occasion of international and other important horticultural exhibitions, where, usually, he has been called upon to act as a judge of Dahlias and other florists' flowers.

MR. A. E. AMOS.

Revival of the Devon and Exeter Horticultural Society.—Like the Norfolk and Norwich Horticultural Society, the above Society was founded exactly a hundred years ago, and is one of the oldest in the country. From its formation in 1829 until 1915, the Devon and Exeter Society held, altogether, two-hundred-and-fourteen shows. For many years the summer show at Northernhay, just within the old city walls, was noted for the excellence of the trained stove and greenhouse plants, and the beauty of the miscellaneous groups of plants, while the Chrysanthemums at the autumn show in the old Victoria Hall were of equally high quality. But during the later years, the Committee was usually embarrassed financially through small gates, and this, combined with the war period, decided the fate of the Society (for a time) in 1915, when the last show was held. But we are glad to know that local horticulturists have made up their minds to revive the Society which did such good work over a long period, and a show is to be held in the Civic Hall, Exeter, on November 14 and 15 next. Already several valuable Challenge Cups have been promised, and it is confidently expected to arrange a schedule of prizes worthy of the old traditions of the Society. Colonel Radcliffe, C.I.E., D.S.O., is the President, and Mr. G. W. Jackson is Hon. Secretary of the Society.

Smith's Advertiser's Handbook.—As a guide to nurserymen, florists and horticultural sundriesmen, in fact, to all tradesmen who make a practice of advertising their wares, *Smith's Advertiser's Handbook*, published by Smith's Advertising Agency, Ltd., 100, Fleet Street, London, E.C.4 (price one guinea), should prove of great value, as it contains practically all the information required for advertising either on a limited, or an extensive scale. There is a classified press index, and a press guide which is very comprehensive, giving the net sales of many of the publications, the scales of charges for advertising in each, and various other important details. The "Traders' Guide," another section of the publication, contains the principal shopping centres, with classified information regarding their population, market days, industries, etc., while there are also guides to class distribution and outdoor advertising in Great Britain. The *Handbook* is beautifully bound and well printed.

Legacies to Gardeners.—The late Alderman Benjamin Hurst, J.P., of Burbage Grove, Hinckley, Leicester, who died on December 20, 1928, left £50 to his gardener, Mr. David Allen.—The late Miss Mary Charlotte Enderby, of Marley Mere, Shottermill, Surrey, who died on November 18, 1928, left £50 and her cottage, known as The Mount, at Marley Mere, Shottermill, to her gardener, Mr. William Wright, "In gratitude for his long and faithful service to me."—The late Mr. William George Blagden, of Heath Road, Petersfield, Hants., who died on November 17, 1928, left £50 to his gardener, Mr. Edwin Hunt, if still in his service.

Royal Scottish Arboricultural Society.—At the seventy-sixth annual meeting of this Society, held at Edinburgh, on Friday, Sir Hugh Shaw-Stewart, Bart., was re-elected President, and Professor Wright Smith, Royal Botanic Gardens, Edinburgh, and Mr. John Michie, Kincairn, were elected to fill the vacancies as Vice-Presidents, while the following members were elected to fill the vacancies on the Council:—Mr. John Alexander, Edinburgh; Mr. John Clark, forester, Gordon Castle; Mr. J. Hunter Blair, Blairquhan, Maybole; Mr. William Munro, factor, Darnaway, Forres, and Mr. William L. Scott, forester, Douglas Castle. The Annual Report stated that the membership numbered 1,626, a decrease of ninety-four, due mainly to an unusually heavy death-roll of forty-seven. Mr. Charles Buchanan, Pinicuik, reported on the summer excursion to be held in the county of Angus from June 24 to 28, with Edzell as the headquarters. On the motion of Sir John Stirling Maxwell, a Committee was appointed to consider whether any changes were required in the constitution or policy of the Society in order to extend its usefulness and activities. At the annual dinner, held in the evening, and presided over by Sir Hugh Shaw-Stewart, Sir J. Stirling Maxwell, in proposing the toast of "Forestry," said they were now in the last year of the ten years for which the Forestry Commission was appointed, and he was glad to say it would come within a short distance of fulfilling the task which was allotted to it. It had to plant 150,000 acres with three-and-a-half millions of money in the ten years, and it would fall short of that area by about 15,000 acres, that being accounted for partly by the changes made in the programme, and partly by the fact that the fund had to bear the expense of about £40,000 spent on the relief of unemployment. The number of forest holdings created up to date in Scotland was 151. In England, 800 holdings would be created by the end of the ten years. In England forty holdings were occupied by ex-miners, but he was sorry to say they had only been able to settle seven ex-miners. Lord Clinton had been able to arrange with the Government that their successors would have £5,500,000 for the work, and they would be able to plant about 25,000 acres a year. It was part of the bargain that £1,000,000 out of the £5,000,000 was to be spent in the creation of forest holdings. Professor Stanfield proposed "The Royal Arboricultural Society," and the Chairman replied.

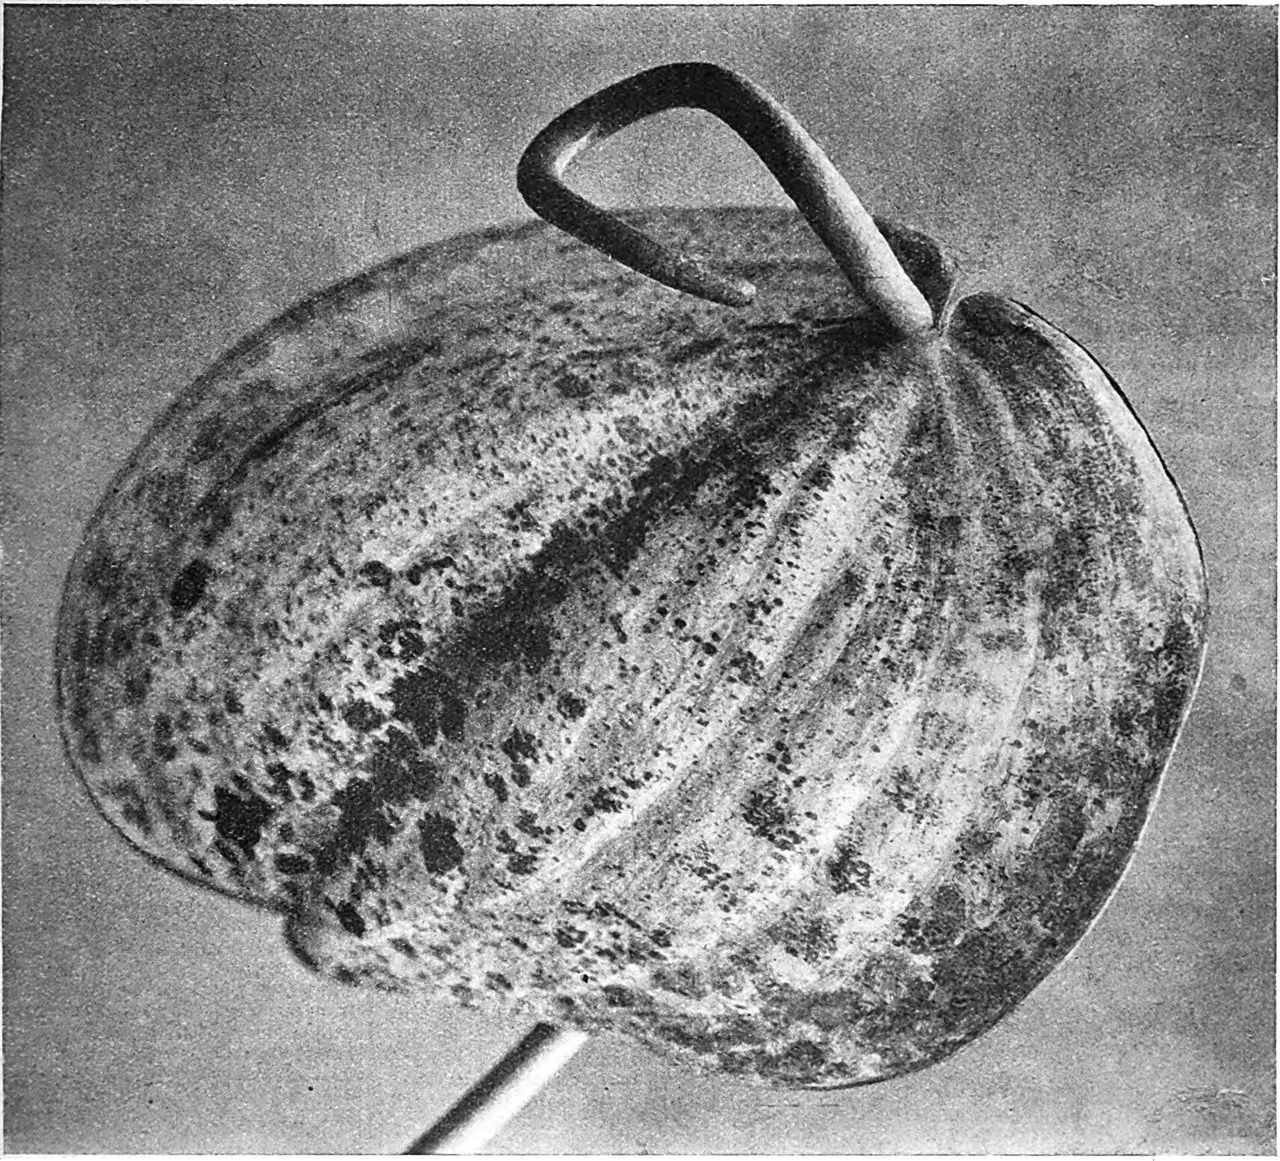

FIG. 50.—ANTHURIUM ROTHSCHILDIANUM VAR. EXCELSIOR.
R.H.S. Award of Merit, January 29. Spathe creamy-white, marked with red. Shown by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Southampton.
(see pp. 89 and 93.)

Anthurium Rothschildianum var. Excelsior.—Messrs. Sanders, St. Albans, inform us that Anthurium Rothschildianum var. Excelsior, described in our issue of February 2, p. 89, and figured above, was cultivated and brought to the R.H.S. Hall by them but was purchased by Lionel de Rothschild, Esq., Exbury, Southampton, who, however, would like to have the Royal Horticultural Society's Award of Merit confirmed to Messrs. Sanders and not to himself. We understand the Council of the Royal Horticultural Society has been advised to this effect.

Appointments for the Ensuing Week.—MONDAY, FEBRUARY 11: East Anglian Institute of Agriculture's lecture; Birmingham and Midland Gardeners' Association's lecture; Derbyshire Horticultural Association's meeting; Harrogate and District Horticultural Association's meeting. TUESDAY, FEBRUARY 12: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting; Faversham Chrysanthemum Society's meeting; Sundridge and Brasted Society's meeting. WEDNESDAY, FEBRUARY 13: Sheffield Chrysanthemum Society's lecture; Royal Gardeners' Orphan Fund Annual Meeting at the R.H.S. Hall, Vincent Square. FRIDAY, FEBRUARY 15: Manchester and North of England Orchid Society's exhibition. SATURDAY, FEBRUARY 16: Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Messrs. Henderson's Nursery, Pine-Apple Place.*—The show house here is already gay with Hyacinths, among which Grand Vainqueur, white; Nimrod, single, blue; and Mars, red, were conspicuous; also spring-flowering Heaths, Cinerarias, Linum trigynum, which is a really useful plant at this season; Genista racemosa, Chinese Primulas, both single and double; Narcissi and the Oleander-leaved Eriostemon. The pretty little Cyclamen coum has likewise been in full bloom ever since Christmas. Of this variety too much cannot be said; it is exceedingly beautiful, and no greenhouse should be without it. In a long span-roofed house was a number of plants of the Sikkim Rhododendron ciliatum, well set with flower buds. Though quite hardy, this is a neat kind for a pot; it occupies little room and is therefore very suitable for small houses in which variety is an object. A degree of elegance was imparted to the flat front shelf of this house by introducing here and there among the small plants which it contained the variegated Aloe-leaved Yucca, with fine heads of yellow-striped leaves set on thick, gnarled trunks, a foot high or so, gave the whole quite an exotic appearance. The stove is becoming gay with Amaryllids. By potting these at different seasons, they may be had in succession for a long time, and the display which they make should not be overlooked by those who are fond of showy flowers. Aeschynanthus ramosissimus was likewise in blossom, as were various Begonias and Thyracanthus rutilans, a scarlet-flowered plant which promises to be very useful. The red-leaved Dracaena ferrea and terminalis served to enliven the monotony which too commonly prevails in plant houses during winter and early spring. Some small, coloured glass vases suspended from the roof, and filled with Lycopods, Ferns, and plants of that sort, were also objects at once striking and interesting, and we should think their skilful introduction into plant stoves generally would help to break the uniform appearance they too often present. *Gard. Chron., February 11, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Pleiones.—The late-flowering specimens of P. Hookeriana, which are now in flower, should receive attention at the roots directly the flowers are over, as new roots will be produced more quickly as the days lengthen, and these are easily damaged if allowed to grow long before repotting is done. These deciduous Orchids thrive best when fresh rooting material is afforded annually. Well-drained pans should be used, and a compost of equal parts of A.1. fibre, fibrous loam and chopped Sphagnum-moss, adding crushed crocks to keep it porous. Rough portions of compost should be placed over the drainage to keep it free; if the compost is built up cone-shaped and the pseudo-bulbs placed in small clumps fairly closely together, each with a small tuft of old roots attached to keep it steady, a much better effect is produced when they are in flower than if they are grown on one level. The soil should be worked firmly between the clumps, which should be distributed evenly in the receptacle, while the surface should be finished off with a little extra Sphagnum-moss. They should be grown in a light position or suspended from the roof at the cool end of the intermediate house, care being taken that they do not come into contact with the glass. Very little water will be required for some time after repotting, until the roots and growths are advancing, when more will be required. Later in the summer, as the pseudo-bulbs are swelling, occasional applications of soot-water should prove beneficial, and at this period the compost should not remain dry for any length of time. When growth is complete and the leaves turn yellow and commence to fall, drier conditions should be afforded until the young growths and flower-buds appear. The earlier-flowering Pleiones, P. lagenaria, P. praecox, P. maculata and others, which were repotted after flowering, are now rooting freely, and need an increased supply of water each time the soil appears dry. Later, during hot weather, the undersides of the leaves should be syringed frequently to keep red spider in check.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—Last month was anything but favourable for a start with early forcing of Strawberries, for although we had many sharp frosts, the sun seldom penetrated the fog. Dry fire-heat has played an imperative part in maintaining the very moderate temperature of 40° to 45° by night, and a few degrees higher by day. Where the earliest plants are producing their flower stems and young leaves are appearing freely, water may be given more liberally, especially if the pots are well filled with roots. It is a mistake to think Strawberries cannot be over-watered; this is easily done early in the year, but an experienced person can tell by the appearance of the plants when they require water, and then, without wetting the crowns, liberal supplies should be given. A camel-hair brush or rabbit's tail should be lightly passed over the flowers each day, when the temperature has reached its maximum. When well set, complete the thinning of the fruits to six or nine. Syringe the plants well and remove them to shelves near the glass in the warmest house at command, feed them well until the fruits show signs of changing, when clear water should be given, the supply being gradually reduced when the berries are well-coloured. Later plants of the leading kinds, in somewhat larger pots, should now be placed in light pits, as close to the glass as possible, and with the aid of a bed of fermenting leaves, the pit can be kept at a temperature of 45° to 50° on mild nights and a few degrees higher by day. On no account should they be hurried into growth, therefore give them plenty of air whenever conditions are favourable. As the early batches are moved forward the most promising of these later plants may be used to fill up the shelves, and in this way a succession may be maintained until the plants in cold pits begin to ripen their fruits. Once the warm weather arrives, Strawberries in pots will require plenty of water and liberal feeding with liquid and other stimulants to bring out their best qualities.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Dahlias.—Where these deservedly popular plants are grown in large quantities, it is now time to place the tubers in heat to provide a supply of cuttings for propagation. Some growers place the tubers on benches, others in boxes; at Wisley, where a large number of varieties is grown, we find it most convenient to place each kind separately in pots of sufficient size to accommodate two or three roots of each. By doing so, there is less chance of the stocks becoming mixed when cuttings are being taken. The multitude of varieties in each section is bewildering and is constantly being added to. A good guide to those who desire varieties suitable for garden decoration will be found in the lists published annually in the R.H.S. *Journal* of those that have received an Award of Merit or been highly commended in the yearly trials at Wisley. These plants are grown without any disbudding, and the awards are made after they have been carefully examined by the Dahlia Committee from the point of view of their value for garden decoration. This does not imply that others which have not received an award are of less value, as many good varieties are put into commerce that are not sent for trial.

Planting.—Every opportunity, from now onwards, should be taken to finish the planting of herbaceous borders and shrubberies as the ground becomes friable and in workable condition.

Michaelmas Daisies.—The strongest-growing varieties of Michaelmas Daisies give the best results if they are lifted and divided every year. When planting, only use the vigorous young growths around the edges of the clumps. Many kinds are best if only single shoots are planted. This principle may with advantage be carried out in the nursery or reserve garden if the plants are required for filling beds in the flower garden for autumn, as the majority transplant easily just before flowering; this is a useful method to adopt where a continuous display is required in the flower garden. A selection of useful varieties will be found in the following. In the Amellus group, plants of which should not be divided until spring, will be found many useful varieties for grouping near the front of the border, best among them being Frikartii, a remarkably free-flowering variety of looser habit than most members of the group; King George, Ruby, superbus, Robinsonii and Sonia. In the Novae-angliae group, Barr's Pink, with semi-double, rose-pink flowers, is the best, while Margaret Ballard, Royal Blue, Maid of Athens, Queen Mary, October Dawn, Little Pink Lady, Aldenham Pink, Nora Rogers, Wedgwood and Delicata, will be found useful representatives of the Novi-belgii section. Of the small-flowered Ericoides group, Doris, Twilight, Milky Way, Rosy and Progress should provide a useful selection. Silver Spray, of recent introduction, ought to prove of great merit.

Salvia virgata nemorosa.—This hardy herbaceous plant, frequently met with in herbaceous borders, is equally valuable for furnishing large beds or banks in the flower garden. The reddish-violet flowers are borne with great profusion over a long period, while the plants are of a sturdy, erect habit, only requiring the support of a few light twigs to keep them in position. This Salvia makes an effective ground work for Lilium auratum. It may be increased readily by cuttings or divisions.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hatfield, Hertfordshire.

Cinerarias.—The earliest Cineraria plants in the greenhouse are now showing their flower buds. They have filled their receptacles with roots and now need watering more frequently. Stimulants should also be applied in weak form, alternately with the waterings. The later plants may be kept growing steadily in a cool greenhouse or pit in which only sufficient heat is maintained to exclude frost. Cinerarias are very subject to attacks of aphis, but light fumigation with a nicotine compound, or spraying with Quassia extract once a fortnight, should keep the plants free from this pest.

Hyacinths, Freesias, Narcissi, etc.—Specimens of these which are developing their flower stems should be stood on shelves near the roof-glass to encourage sturdy growth. They should be introduced to the forcing house in small batches, so as to prolong the supply of flowers.

Richardias.—Plants of Richardia africana, the Arum Lily, that have been grown under cool conditions during the last few months with a view to their producing blooms in succession to the late Chrysanthemums, should now be commencing to flower freely, and to obtain the best results they should be given liberal applications of liquid manure and soot-water, which will keep them in a healthy condition. When producing their flower spikes, the plants require applications of these stimulants at least twice a week. If space is available for them to be planted out under glass, they should thrive and produce flowers in quantity, but even under these conditions they require some assistance from fertilisers to ensure the production of good spathes. A batch of Richardia Elliottiana may now be potted, using receptacles according to the size of the tubers; it will be wise to place them in receptacles rather on the small side, than to overpot them. Only fill the pots to half their depth with compost, so that ample room is left for top-dressing when the plants have started to grow freely. A temperature of 55° will be suitable to start them into growth. Care should be taken not to overwater them, but when they are in active growth and the pots are well filled with roots, they will require liberal supplies of water and liquid manure. R. Pentlandii requires similar treatment to that advised for R. Elliottiana.

Cyclamens.—Cyclamens raised from seeds sown last August, and which are now in shallow boxes or pans, should, if all has gone well with them, be ready for placing singly in small pots. The compost for this potting may consist of equal parts good open loam and leaf-mould, with a liberal sprinkling of silver sand added to keep the soil porous; old red bricks, broken very finely, and charcoal, should also be mixed with the compost. Do not pot the plants too firmly. A night temperature of 55°, with a rise of 10° during the day, should suit the young plants at this stage, while the house should be fumigated lightly on frequent occasions to keep aphis and mite in check.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

Peach Leaf-curl (Exoascus deformans).—This fungus disease rarely attacks trees grown under glass, but is only too common on Peach and Nectarine trees when grown against walls in the open, especially during a cold and dull spring. Its attack is chiefly confined to the leaves, causing them to become fleshy and distorted; but it also attacks the young growing shoots, causing considerable malformation. Any deformed or dead shoots should be cut back now to healthy wood, and while the branches are free from the wall they should be sprayed with Burgundy mixture, which may now be obtained in powder form; it requires no preparation, except the adding of the requisite quantity of water, and after being well stirred it is ready for use. Every endeavour should be made to wet every portion of the tree, particularly the young twigs and buds, as re-infection, as a rule, is caused by spores which have lain dormant during the winter in the angles formed between the leaf-buds and the twig, and under the bud scales. A second application is advisable just prior to the bursting of the buds.

Apple Blossom Wilt and Apple Brown Rot.—These two diseases, although distinct, are closely allied. The same measures of control should be applied for both, viz., cutting all diseased spurs and shoots back to sound wood, and spraying, just prior to the bursting of the buds, with soft soap and ammonium polysulphide. The buds should be just on the point of bursting into leaf for this wash to have the best effect, and as it may be mixed with soft soap and nicotine, it serves the dual purpose of being a fungicide and an insecticide. At this period, aphis of all sorts, Apple sucker, caterpillars and capsid bug, will be on the move, and this combined wash will do an immense amount of useful work. The ammonium polysulphide is employed at one per cent., with the addition of 8 lbs. to 10 lbs. of soft soap to soften the water and improve its wetting and spreading qualities, and five ounces of nicotine of 95 per cent. to 98 per cent. purity, to every one hundred gallons of water.

Big Bud Mite of Black Currants.—Whether this pest is present or not, all Black Currant bushes should be sprayed now with one or other of the tar-distillate washes at five per cent., to destroy the eggs of aphis wintering on the bushes, for aphides are responsible for the spread of mite and "virus" diseases, such as "reversion." Having once got rid of aphis, we have, to some extent, limited the spread of big bud mite. This measure, however, must be followed up a little later by the application of a strong lime-sulphur wash, *i.e.*, one in twelve, and the most effective period for this is when, on healthy growths, the flower trusses appear outside the buds but the flowers have not actually opened. Mr. Lees, of Long Ashton, describes the right time for spraying as "when the leaves are about the size of a sixpence." These leaves may, after being sprayed, show a certain amount of scorching, but the loss caused by this spraying is infinitesimal compared to the amount of good resulting.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunstar, Somerset.

Tomatos.—A sowing of Tomato seeds may be made now, to have plants ready for planting out early. Autumn-raised plants should be ready for shifting into six-inch pots, using a good, rich and well-mixed compost of loam, sand and leaf-soil, with some wood-ash added. Excessive heat in the Tomato house should be avoided, and the plants should be kept as near the glass as possible to ensure sturdy growth. Plenty of air should be admitted during fine weather, but have plenty of covering material at hand with which to protect the plants during frosty weather, as Tomatos are naturally very tender.

Asparagus.—If new Asparagus beds are to be made, they should be prepared now, marking off the beds five feet to six feet wide; this width should be sufficient for three or four lines to each bed. To make the bed, remove the soil to a depth of about eighteen inches, then deeply fork the bottom and put in any vegetable refuse that may be available, covering it with a good layer of well-decayed manure. When the top soil is replaced, the bed will be found to be much higher than it was before, but if left undisturbed it will gradually settle and sink considerably before planting time, the end of March or early April, arrives. Very little is gained by growing Asparagus plants for two or three years from seeds to supply plants for forming new beds, as crowns may be procured at reasonable prices and in splendid condition, from a nurseryman. However, if it is desired to raise Asparagus plants, seeds may be sown now in boxes, and the seedlings, when large enough to handle, pricked out into boxes or, better still, frames, in which they may be grown on steadily for one season, planting them out the following spring. For the sowing of Asparagus seeds out-of-doors, April will be early enough. They should be sown in drills twelve inches or more apart and two inches deep, in ground in which they may remain for two years, after which they should be separated and replanted.

Onions.—The seedling Onions that were sown under glass should now be ready for pricking out into boxes. These should be of suitable size, and each, after having a layer of decayed manure placed at the bottom, should be filled with a compost consisting of half-a-part loam, a quarter-part leaf-mould, and a similar quantity of sand, which should be pressed fairly firm. Care is needed when handling the young plants, as they are very easily broken and damaged. Place the boxes of seedlings in an early vinery, and spray the plants once a day with tepid water.

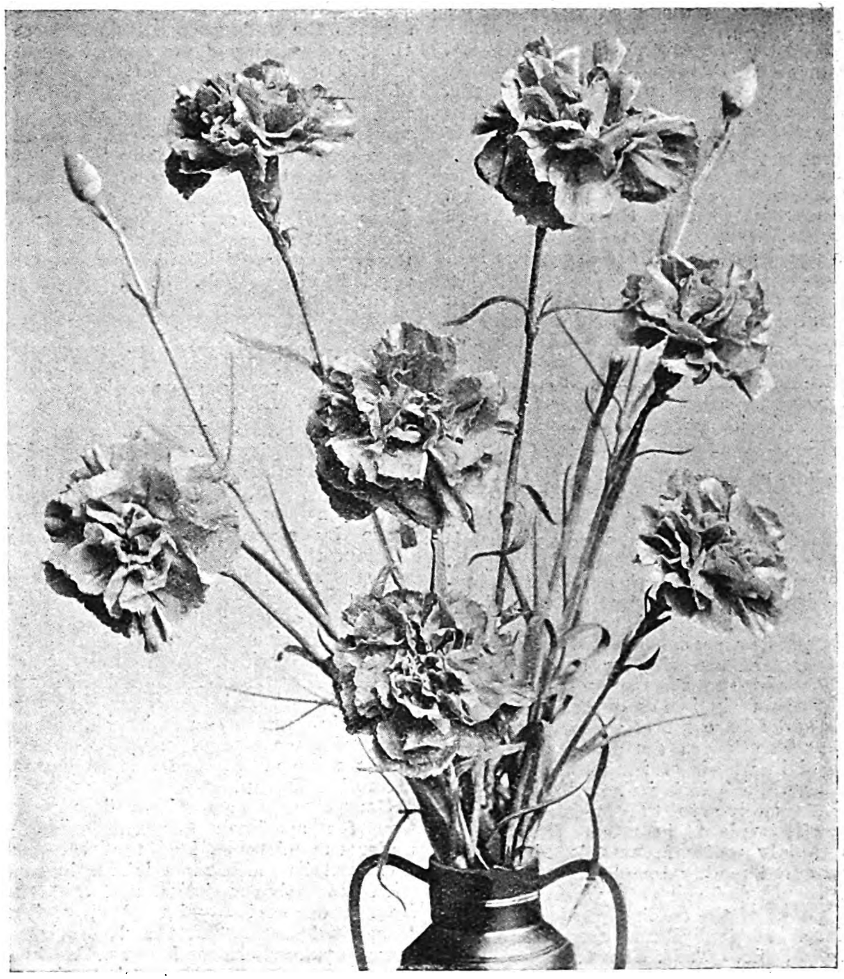

FIG. 51.—CARNATION KATHLEEN.
R.H.S. Award of Merit, January 29. Flowers light rose-pink, sweetly scented.
Shown by Messrs. Stuart Low and Co. (see p. 89.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Potatos.—As seed-sets of Potatos are obtained, they should be set out in boxes in single layers, standing each tuber on end with the eyes exposed; they may be kept for a week or two in a glasshouse, but must not be forced too much, and should be placed in a cool shed for a fortnight previous to planting. The advantages gained by sprouting the tubers is obvious, and if many eyes burst, remove all but one or two of the shoots at planting time.

Parsnips.—To produce a good crop of Parsnips seeds should be sown whenever the ground is in suitable condition, as they require a long season of growth to produce good roots. A plot which was heavily manured for the previous crop—Celery or Onions—is most suitable, provided it is worked deeply some time previous to sowing the seeds. A good tilth is necessary, and the seeds should be sown thinly in rows two feet apart, covering them, especially if the soil is heavy, with some sifted, old potting soil. Firm the soil with the feet and do not obliterate the rows with a rake, so that the progress of the seedlings may be watched.

Spraying.—As the fruit trees will soon be commencing growth, all winter spraying should be completed at the earliest possible date. Where mildew, Peach-leaf curl, big bud on Black Currants, or moss on the trunks of trees, have to be dealt with, there is no better spray for dealing with them than lime-sulphur. For all insect pests on fruit trees and bushes, one of the tar distillate washes, or any of the caustic alkali washes should be used, care being taken to wet every part of the tree. If a spraying machine, or a hand sprayer for small quantities, is used, spraying should not be an expensive operation, and the results amply justify it. Roses of all kinds should be sprayed once or twice during the early spring to destroy the resting spores of black spot and mildew, any of the sulphate of copper mixtures being suitable for this purpose.

Half-hardy Annuals.—Many half-hardy annuals may now be sown in pots or boxes of fine sandy soil, either in a warm house or in a frame. Sow the seeds thinly and remove the seedlings, so soon as they are well up, to a cool house, placing them near the roof-glass, to encourage short, sturdy growth.

Cyclamens.—These are now making a brave show and must not be allowed to become dry at the roots; applications of very weak liquid manure will assist them to continue in flower, but this should only be given when the compost is damp.

INDOOR PLANTS.

BEGONIA ULMIFOLIA.

This Columbian species should be included in every collection of fibrous-rooted Begonias, for its distinct habit and handsome foliage combine to make it a plant of decided value for growing in conjunction with other species and varieties, while the white flowers, although by no means so beautiful or showy as those of many other Begonias, make a pleasing relief to the more prevalent pinks and reds.

The plant under notice is of erect, branched growth, having stout, green, semi-succulent stems, marked with small, white specks, and with a reddish tomentum. The leaves are shining green above and greyish-green beneath. They are rather distantly spaced along the stems, and have short petioles and prominent, scarious stipules. As the specific name suggests, they resemble those of the common Elm, being from three to eight inches in length, ovate-oblong, unequal at the base, and abruptly short-jointed; the margins are doubly serrate, and the venation is very strongly marked, the veins running in pinnate fashion from the mid-rib. Both the upper and lower surfaces are covered with soft, scattered hairs. The flowers are borne freely in peduncled clusters. They are greenish-white in the bud, but open a clear white. The staminate blooms usually have two equal petals, and are about one inch in diameter.

An intermediate house temperature and a humid atmosphere suit Begonia ulmifolia, while it should be provided with a rich compost, as it is a gross feeder. Starved plants quickly turn yellow and drop their leaves; it is therefore essential to feed pot-bound specimens liberally with dilute liquid manure, soot-water and approved proprietary fertilisers.

MYRIOPHYLLUM PROSERPINACOIDES.

The plant upon which botanists have bestowed this somewhat unwieldy name is known more commonly as the Parrot's Feather. It is included in the Natural Family Haloragaceae, and is a beautiful subject for cultivating in greenhouse tanks and in aquaria. When planted in pots or pans beneath two or three inches of water, the slender stems spread themselves along the surface and raise their extremities about six inches out of the water. The stems and foliage are of a most attractive green hue. The leaves are feather-like, and are arranged in whorls of from four to seven. They are about one inch in length and finely divided into twelve to twenty-five hair-like segments. The plant branches freely and increases rapidly under favourable conditions. It is propagated readily by means of cuttings dibbled into pans of soil and placed in water so that the tops of the cuttings protrude above the surface. Myriophyllum proserpinacoides is a native of Chile. *T. H. Everett.*

FREESIAS FROM SEEDS.

The flowering season of the deliciously perfumed Freesias might be prolonged if seeds were sown to provide plants to follow those grown from corms.

Seeds of F. refracta alba may be obtained from any reliable seedsman, and it is a surprising fact that blooms obtained from seed-raised plants are much better than those from bulbs. The seeds may be sown towards the end of February or early in March. As seedlings of this subject will not withstand transplanting very well, it is advisable to sow the seeds in their flowering pots, which may be either five or six inches in size. The Freesia delights in a compost consisting of one part leaf-mould, one part sand, and a little well-decayed manure, mixed well and passed through a fine sieve.

A quantity of coarse mould should be placed in the seed pots and then covered with about an inch or more of the compost. Sow about four seeds in a five-inch pot, and seven in a six-inch one, and cover them to a depth of half-an-inch with fine compost. The seeds will germinate best in a cool house, and no harm will be done should the temperature rise to 70° or 75° through sun-heat in the early stages, but later, the plants should be kept cooler. In about three or four weeks from sowing, tiny blades of "grass" will commence to appear through the surface of the soil, and at this stage plenty of air, without draughts, should be admitted whenever possible.

By the middle of May the seedlings should be ready for removing to a cold frame, where they will make plenty of headway provided they are protected from frost; when all danger of frost is over, the pots may be placed in the open on an ash base.

Freesias, in a natural state, are great lovers of water, and are often found growing on the banks of a running brook or stream. This being so, they should be grown under as nearly natural conditions as possible. They require watering frequently, but beyond this and the removal of weeds, they need no further attention.

As a rule, it is safe to estimate that the plants will flower in six months after the seeds were sown, although some may bloom earlier. So soon as the buds appear it is time to remove the plants under glass.

Thus, it will be seen that, where a succession of sowings is made, at intervals of three weeks, one may have a continuous supply of Freesia blooms from August onwards, until the plants from seeds are succeeded by those grown from corms potted up in summer or autumn.

The later-sown batches may be left out-of-doors until the end of September, while, to develop the growths and increase the size of the flowers, weak liquid manure should be applied twice a week. *G. B.*

JAPANESE CHRYSANTHEMUMS FOR LARGE BLOOMS.

The popularity of the large-flowered Japanese Chrysanthemums was evident at the N.C.S. Exhibition, held at Westminster on November 1 and 2 last, when many enquiries were made by amateurs who were anxious to attempt the cultivation of exhibition blooms. Those exhibited by the President of the Society were models of perfection, and proved that the exhibiting of large blooms in vases is a much more attractive way to display their charms than the more widely practised method of staging the blooms on boards. To display the full beauty of the flowers, it is necessary that the staging be no higher than twelve inches. The arrangement of three blooms in a large vase is ideal, and a table of selected colours makes a very attractive display.

Garden owners sometimes discourage cultivation for specimen Chrysanthemum blooms, under the mistaken idea that the growing of these entails much more labour in comparison with decorative varieties, and that the effect, from a decorative point of view, is fleeting. Most gardeners realise the decorative value of large Japanese blooms for grouping in the conservatory and appreciate their lasting qualities. They are full of interest, and attractive from the time the buds show colour until long after they have reached their best.

Although many excellent new varieties are being sent out by raisers, a few old favourites are difficult to dispense with, notably, Mrs. Gilbert Drabble, W. Rigby, Lady Talbot, Mrs. Algernon Davis and Mrs. R. C. Pulling. One of the finest varieties in commerce, T. W. Pockett, was not shown extensively at the show mentioned above. Probably this was due to the early date on which it was held. This is a reliable variety in the eastern and midland counties, but not always a success in the west of England. Its tendency to coarseness may be overcome by stopping the plants during the last week of March and securing second crown buds. Grown in this way, the flowers have lasting qualities, in a cut state, second to none; it is therefore a desirable variety to grow where large flowers are in demand for cutting.

Majestic and its two sports are, perhaps, the three most popular varieties in cultivation, and appear in practically all exhibits, wherever a show is held. In order to obtain buds which will develop in time for the November shows, these varieties require stopping about mid-April. This also applies to Mrs. G. Drabble, W. Rigby and Princess Mary. Good yellow Japanese Chrysanthemums are plentiful. In addition to those already mentioned, we have the newer varieties Charles Davis (1928), and Lady Miller, both first-class and quite distinct. Really good crimson sorts are not so plentiful; for colour, Mrs. G. Monro, jun., is an easy first, but it lacks size. Thalia, a recent introduction, will be grown largely on account of its vigour, increased size and reliability. Birmingham is of good form and is a solid, well-built flower, while a good, reliable white variety to grow is Mrs. Arthur Brown, which may be allowed to break naturally, securing the first crown buds. Mrs. B. Carpenter is rather like its parent, Mrs. Algernon Davis, but is very popular. These varieties, together with Julia, are best propagated somewhat later than the majority of Japanese Chrysanthemums. The first crown buds may be secured if cuttings are inserted late in December and allowed to break naturally. For decorative purposes these varieties may be propagated early in March and the first bud secured. Seven-inch pots should be large enough for the final accommodation of these late-rooted plants.

Marjory Woolman, Mrs. Peter Murray and Mrs. M. Sargent are dwarf growers and, like the three Majestics, are capable of being satisfactorily housed on side stages or in other positions where head-room is limited.

Most varieties require a long season of growth, a few exceptions being mentioned above, and propagation should be effected during the second week of December. Good, sturdy root-cuttings, about three inches in length, should be inserted about four in a three-inch pot, in a mixture of loam, leaf-soil and sand. The cuttings should be watered in with a fine-rose can and placed in a propagating frame, in a house with a temperature of 48° or 50°. The frame light should be turned each night and morning to dispel moisture, admitting a little air during the night period. Treated in this manner, cuttings should root in about three weeks, when they may be removed from the frame. When a few weeks have elapsed they should be ready for potting singly into three-inch pots. From February onwards the plants should thrive in a light, airy pit, where a little heat is available to guard against frost and damping-off. Air should be admitted whenever the weather conditions permit. By early April the plants will require a shift, the larger into six-inch and the weaker into five-inch pots.

The soil used for the April potting should consist of three parts good fibrous loam, one part leaf-soil, a quarter-of-a-part manure from an old Mushroom-bed, and a quarter-of-a-part sand and lime rubble. A four-inch potfull of bone-meal may be added to each bushel of compost and rather more than this quantity of wood-ash. Mixing the soil should always be done some days before it is required for use. The plants require fairly firm potting at this stage, and may be returned to the pit or a cold frame, and kept rather close for a day or two. As they are potted, a small stake should be supplied to each plant. Water need not be applied for a day or two, when all the plants should be watered thoroughly. As the roots develop, air may be admitted more freely, and gradually the lights should be removed during the day-time whenever the weather is mild. By the second week in May it is safe, in most districts, to stand the plants out-of-doors, but some provision should be made for overhead protection in case of frosts or hail.

By early June the plants should be potted into the receptacles in which they are to flower. Strong plants will need a pot having a diameter of ten inches, or possibly eleven inches. The soil for this final potting may be left in a rougher state than that used in April. A smaller proportion of leaf-soil may be added, but otherwise the mixture should remain unchanged. A good open space, with an ash base, is the most suitable for the growing quarters. Wires should be strained along each row, to support the plants against winds.

Crown buds will begin to show early in August and these should be secured, removing all side growths in their young stage. From this time onwards, constant attention should be given to feeding. The aim should be to build up strong buds before the time for housing arrives. It is better to apply light feeding regularly than to give strong doses of liquid or other manure at irregular intervals. Clear soot-water, poultry manure in solution and drainings from the farm buildings, are all good; and may be diluted and applied in turn, a week at a time. The diluted liquid manure should be similar to brandy in colour. A top-dressing of an inch of compost similar to the potting mixture, omitting bone-meal in favour of a special Chrysanthemum fertiliser or Clay's manure, should be applied late in August, and made firm with a rammer. For about ten days after applying the top-dressing clear water only should be used for watering, but later the applications of liquid manures may be renewed and continued up to the time of housing the plants. Buds showing colour need protection from frosts or heavy dew, or they will eventually show signs of damping. For the midlands, September 20 is a good time to commence housing the forward plants, and those with buds not quite so well developed may be brought under cover by October 1.

When first housed, conditions should be maintained similar to those out-of-doors; all doors and ventilators should be left open day and night. If dry, the path may be sprinkled with water. Later, the damping should be discontinued and ventilation adjusted to suit the weather conditions. A night temperature of 45° to 48° should be aimed at.

As the blooms proceed to develop, a little warmth in the pipes is desirable and will counteract the tendency to damp, but air may be admitted always through the leeward top ventilators, no matter what the weather is like, except in the case of dense fog. As a preventive against mildew, the plants should be sprayed with sulphide of potassium, one-third-of-an-ounce to a gallon of soft water being the necessary strength; as this discolours paint, it should not be used on plants after they are housed. Flowers of sulphur may be used to check any signs of outbreak while the plants are under glass. October sunshine sometimes scorches the petals, and a thin layer of some shading material is needed, especially on the east side of a span structure. The shading should not be so dense as that usually applied for the protection of greenhouse plants in summer. *Charles Hodgson.*

HARDY CYCLAMENS.

The Cyclamens are very popular in gardens, and we may easily understand why. Some of them have been cultivated since the sixteenth century. Mr. Baker published a description of them in *The Gardeners' Chronicle* of March 1883, and Professor Hildebrandt published, in 1898, a good monograph of them; then Pax, in *Engler's Pflanzenreich*, published a monograph in 1905. Therefore we are well informed about this fine genus, but to know the plants well one must cultivate them.

Cyclamen tubers are generally hardy, and sometimes they become very big and very old. In *Gard. Chron.* (March 6, 1920) a correspondent from Glarus, Switzerland, contributed a photograph of a pot Cyclamen europaeum he had grown about sixty years, and Mr. Purpus of Darmstadt wrote in the *Deutsche Gaertner Zeitung* that he knew some tubers more than a century old. In the *Garden Magazine* (January 21, 1893), Mr. Stapely, of Staplehurst, Kent, stated that he had some bulbs of C. persicum older than forty years, each bearing more than five hundred flowers in a year.

All, or almost all, Cyclamens prefer calcareous to acid soil and sometimes they are very deep in the soil. All like a well-drained position, as the tubers rot easily. The seeds are covered with a kind of honey, and the ants are their distributing agents. We may find that some seeds, and these are rather heavy, have been transported seven, or even more than eight metres away from the plant.

At the end of January we have an underwood bright with the carmine flowers of Cyclamen coum and C. ibericum, all mixed together by cross fertilisation, which is a plague for the seed-grower. Some of our C. ibericum, from Tiflis, have to be isolated under glass in order to retain their character; it is also the same with C. coum. Out-of-doors they cross and multiply with the greatest ease. Those belonging to the small group of winter-flowering, oriental kinds are, C. alpinum, C. coum and C. ibericum; C. Atkinsii is a cross between the two last. All are dwarf, with roundish, kidney-shaped leaves contemporary with the flowers; the blooms are bright carmine with a dark spot, but they vary considerably.

C. coum is the Grecian type, reaching Turkey and Armenia. It appears to be near C. ibericum, but its leaves are dark green on the upper side and deep reddish-brown below; their form is the same, but they are entirely smooth on their periphery, while those of C. ibericum are maculated on the top side and have small teeth, or are irregularly broken into minute, acute angles at the end of the nervures. The flower divisions are elongated, longer and narrower than in C. ibericum, and the sepals are not so contracted at their base as they are in C. ibericum.

C. ibericum flowers here earlier in January than C. coum, and both are inodorus and have bright carmine flowers with a dark spot at the base of the division.

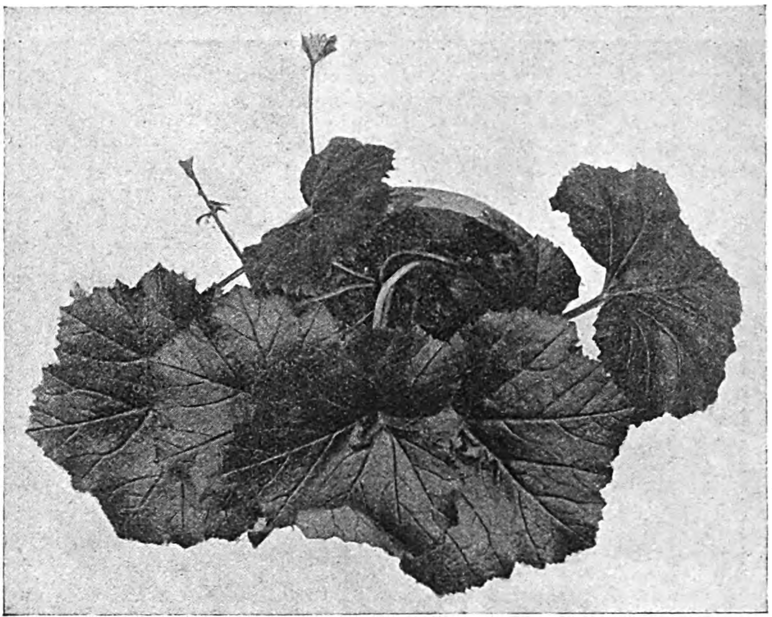

FIG. 52.—CYCLAMEN ROHLFSIANUM.
(Showing form of foliage.)

C. alpinum is the mountain form of C. coum (see *Gartenflora*, 1892, p. 526), and has the smallest leaves of the group. These leaves have the periphery still more irregular than in C. ibericum and strongly maculated (see Hildebrandt's *Monograph*, plate 3), and the petals broadly ovate, acute and shorter. The flowers have a red pistil and are of a rather reddish-carmine. It grows on the high mountains of Anatolia, near the snowfields, just at the melting edge of the snow.

C. Atkinsii has the intermediate characters of the parents and its flowers vary from white to deep rose, with dark marks at the base of the petals.

In March, we begin to enjoy the sweetly-smelling C. repandum (vernum), with light rose-carmine flowers. The leaves come up with the flowers and are ovate-deltoid, cordate at their base, dentate, and slightly whitish-zoned. It is a Mediterranean species, growing in woods in the south of France, Italy and Greece. Its brother, C. balearicum, from the south-west part of France, Spain and the Balearic Islands, is much smaller; its tuber is not bigger than a large Pea and buried very deeply in the gritty and mossy soil. The leaves are strongly maculated with white; they are small and strongly dentate, appearing and disappearing from March to the end of May. The flowers are small, pure white and very fragrant.

C. libanoticum is a rare plant, found some forty years ago by Hartmann on the Lebanon. The leaves are autumnal, obcordate, dentate and crenate, with a white zone; flowers vernal, pale rose, with a deep carmine spot, and very fragrant. These are, with C. latifolium (persicum), which is not hardy with us, the vernal Cyclamens.

In the month of July, C. europaeum begins to bloom. This is the oldest known of our garden Cyclamens. It is one of the glories of the limestone mountains surrounding Geneva, but is not found everywhere, remaining confined to hot, dry and shady, stony slopes. In the north-east of Italy, and especially in the Garda region, and in the Trentino, it grows everywhere. At the very base of the Tombea, near Storo, it grows in the full sun along the road, on limestone pierriers, while in the Carinthian Alps, above Klagenfurth, I found it last year adorning the fresh meadows like a Colchicum. It flowers there with such abundance that, viewing it from far away, I really believod I saw a Colchicum meadow! The leaves of C. europaeum are evergreen, more or less maculated, deep red below (in the white-flowering variety the underside is green), and the very sweetly-fragrant flowers appear in autumn. We have, however, at Floraire, some in flower from July until the end of November; their best position is between rocks in a shady or half-shady place.

C. neapolitanum is well-known and widely grown in England, and also its white variety. The tubers are very large, and the leaves come after the flowers. These leaves are very variable; hence the numerous names under which it is known. Mr. E. A. Bowles has some forms with very hastate, elongated, Arum-like leaves, and, naturally, as all those who know Mr. Bowles will understand, some tubers went into my pocket when I visited him. This is C. neapolitanum var. araefolium.

It is a pity that the flowers of C. neapolitanum have no fragrance, but, as it is, one may consider it as one of the good flowers for underwood in the autumn. The leaves come immediately after the flowers; it is a south European species growing always in shade.

I had obtained from Corsica a form with strongly maculated leaves, but it cannot be recognised as a type; I call it C. neapolitanum var. corsicum. C. graecum has big, red, and very irregular tubers and obovate leaves, strongly dentate, velvet green and maculate on the upperside, but very red below. The flowers are like those of C. neapolitanum, but rather larger. I obtained it from the mountains of Greece.

C. Jovis, named and sent out by Siehe, of Mersina, is an Oriental form of C. neapolitanum, with very elongated sepals and petals, narrowly lanceolate, and with filaments 1 mm. long (almost absent in C. neapolitanum); the leaves also are broader.

C. africanum is the Algerian form of C. neapolitanum, with very large tubers; the leaves appear in December, and are large, beautifully marbled with white, and strongly dentate; the flowers are produced in winter and are pale rose, with a carmine spot at the base; this form must be protected here.

C. cyprium is a very distinct species from Cyprus, with small, heart-shaped, marbled leaves (with an interrupted white zone), reddish-violet underneath, strongly serrate, and appearing just before the flowers in September. The blooms are inodorus, white or pale lilac, with acutely dentate, almost laminate petals.

C. cilicium, from the Orient, develops its leaves with the flowers; they are sub-orbicular, entire, with basal lobes; the flowers are pure white, and fragrant. It belongs to the European group.

In 1898 the Russian botanist Alboff brought me from Abchasia two big tubers of C. europaeum, which he labelled Colchicum (C. ponticum). This has very thick, dark-green leaves, hastate and acute, and bigger flowers than our common type. It seems to be the same thing as C. pseudo-ibericum. Alas, I have lost it for twenty years!

The strangest of all the Cyclamens is C. Rohlfsianum (Figs. 52 and 53), from the Cyrenean desert. It has very large leaves, not only dentate and crenate, but even lobate, beautifully marbled on the very bright upper surface and dark red underneath; these appear in late autumn, just before the flowers. C. Rohlfsianum was found in 1893, and brought into the Boissier's Garden by Mr. Barbey-Boissier, where it flowered, but it has since been lost. In the year 1917, I tried to get a lot of tubers from Bengasi, but they were held up on the way (it was war time), and they took four months to reach Floraire. Alas, they had rotted and were of no use. Then I wrote for seeds, which came to hand and germinated; but we, unfortunately, left the seedlings exposed, and they were all frozen. New seeds have been obtained and a few plants raised. Then my friend, Dr. Raggioneri, sent me from Florence some very big tubers he had secured (one measured 12 cm. broad and 9 cm. thick, and weighed 250 grammes). These rooted successfully and flowered well with us, but gave no seeds, despite artificial fertilisation.

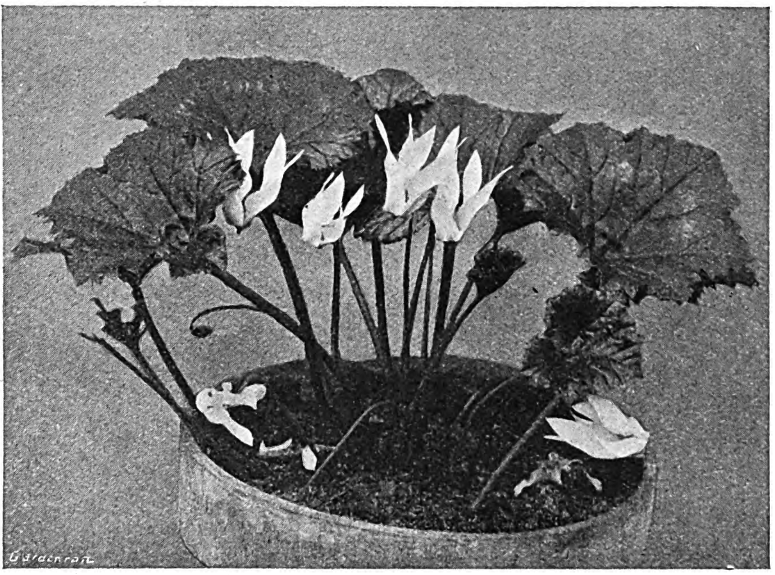

FIG. 53.—CYCLAMEN ROHLFSIANUM.
(Showing flowers and foliage.)

The flowers of C. Rohlfsianum are said to be fragrant in the wild state, but here they are almost inodorous; they are of medium size, light rose, with a carmine spot at the base; their special character is the long, acute anthers which extend beyond the petals like those of a Dodecatheon. This very rare plant grows between the large blocks of stones which form the walls which protect the oases against the encroachment of the desert. It must be protected here in winter. *H. Correvon, Geneva.*

BEGONIAS FOR SUMMER BEDDING.

BEGONIAS, as represented by the tuberous-rooted and fibrous-rooted varieties, are indispensable for summer bedding, and are being used increasingly for this purpose, either alone or in conjunction with light and elegant foliage plants; they have, in many instances, taken the place of the bedding Pelargonium. The reason for this popularity is not far to seek. Tuberous-rooted Begonias may now be had in a wide range of colours; they take up no valuable space in greenhouses during the winter months; they are cheap, and if it is necessary to purchase dry tubers, they may be obtained true to colour; while they may also be raised easily from seeds, which should be procured from a reliable source.

When dealing with dry tubers, those from seeds sown the previous year are the best, although good results may be obtained from tubers several years old; in fact, it may be, and often is, necessary to cut up the old tubers, or secure cuttings from them, to increase choice, named sorts. The usual practice is to start the dry tubers into growth in heat, afterwards placing them in pots; this method, especially if large quantities are required, entails a lot of labour, and in my experience is unnecessary, in fact, better results are obtained by planting them out in cold frames, in a compost of good loam and plenty of well-decayed stable manure or leaf-soil, with enough sand added to keep it open and porous; it is important to plant them in a fairly loose, free-rooting medium.

If it is desired to grow them by this latter method, the dry tubers may be planted from the middle of March to the beginning of April; if the frames are kept close and moist the tubers should start quickly into growth, the plants, when hardened-off, being ready to plant out so soon as weather conditions permit, *i.e.*, about the beginning of June.

If so desired, these Begonias may be raised from seeds and the resulting plants bedded-out the same season. For this purpose, seeds should be sown about the middle of February, in a temperature of 60°. The seed-pans should be prepared and the compost watered with a fine-rosed can some hours before it is desired to sow the fine, dust-like seeds. These should be distributed evenly over the surface, after which the receptacles should be covered with a piece of glass, and kept shaded until germination takes place. Subsequent cultural treatment consists of transferring the seedlings to pans or boxes of light compost and, as they increase in size, giving them frequent shifts into other boxes until they are large enough to be planted out in cold frames as advised for dry tubers; it is important that they be kept growing steadily, without any check.

For bedding purposes the single-flowered varieties may be regarded as the most suitable. There are, however, other tuberous-rooted Begonias which are suitable for bedding purposes, the most important, perhaps, being the Worthiana group, in which the best-known are B. Bertinii, B. Bertinii nana, and the newer salmon-pink variety, Madame Mandrot.

There is also a group known as multiflora, which includes a number of dwarf, free-flowering varieties, with double or semi-double flowers; these are generally very free-flowering, and are charming for growing in association with light, elegant foliage plants. A few of the best in this section are Count Zeppelin, Lafayette, Burgomaster Max, Phosphorescent, Flamboyant, and Mrs. Helen Harms, the last-named being the best yellow-flowered variety; Evelyn Tavenet, Alice Crosse and Commander Felix are three new pink varieties of promise. All the above-named varieties must be propagated by cuttings, which should be secured when they are three or four inches in length.

There is, however, a group of Begonia Lafayette hybrids, the members of which may be raised from seeds; they have fine, dark-coloured foliage and brilliant, scarlet flowers.

Begonia fulgens and B. gracilis are both excellent bedding plants, but they are not obtainable in quantity. The former may be raised from seeds, while the latter produces numerous bulbils in the axils of the leaves and stipules, and these afford a ready means of increase, Begonia gracilis is more generally known as B. Martiana, and should not be confused with the B. semperflorens varieties, which form a section referred to by continental growers under the name Martiana.

The fibrous-rooted semperflorens Begonias, of which there are many varieties, are ideal for summer bedding, as they appear to be indifferent to the vagaries of the weather, remaining effective throughout hot bright spells or dull, wet and sunless weather. It is surprising they are not used more generally for summer bedding arrangements. They are raised easily from seeds, the different varieties coming true to character; they should be sown and treated in exactly the same way as advised for the tuberous-rooted varieties. When transferred to the frames, care should be taken to prevent the young, tender foliage from being scorched by the sun, therefore they should be shaded after being watered overhead. If it is not desired to raise these varieties from seeds every year, stock plants may be kept over the winter and propagated by means of cuttings early in the year. For this purpose it is important to secure basal cuttings, for although flowering shoots root readily, they seldom break into growth. Some good semperflorens varieties which may be depended upon to come true from seeds, are Pink Profusion, Prima Donna, Glory of Erfurt, Luminosa, Broadcast and Bonfire; the last-named has dark foliage and brilliant red flowers, which are really dazzling in bright sunshine.

All Begonias enjoy a rich, free root-run, and the beds for them should be enriched with plenty of well-decayed farmyard manure or leaf-soil. When used for bedding purposes, they are seldom troubled by diseases or insect pests. They flourish under cool and moist conditions, and are therefore to be recommended for planting in the northern parts of the country. *J. Coutts, Kew.*

WATER GARDEN.

BUTOMUS UMBELLATUS.

ONE is often inclined to overlook the members of our native flora, in the quest for plants from overseas. A good example is to be found in the above subject. Although common in many shallow pools or on canal banks, we do not often see it used in water gardens. Yet, with its mass of lax, green leaves, between two and three feet high, above which tower the tall flowering stems bearing umbels of pale pinkish, star-shaped flowers, it is a desirable subject to plant on the margins of large sheets of water. It grows equally well in the bog garden, but, like all aquatics, is so vigorous that it must be kept within bounds. *F. W. G.*

PROPAGATION OF RHODODENDRONS BY CUTTINGS.

(*Concluded from p.* 79.)

An excellent plan, where the right type of wood for cuttings is difficult to obtain, is that of potting up a good stock plant and placing it in gentle heat under glass, when a supply of good cuttings will become available readily.

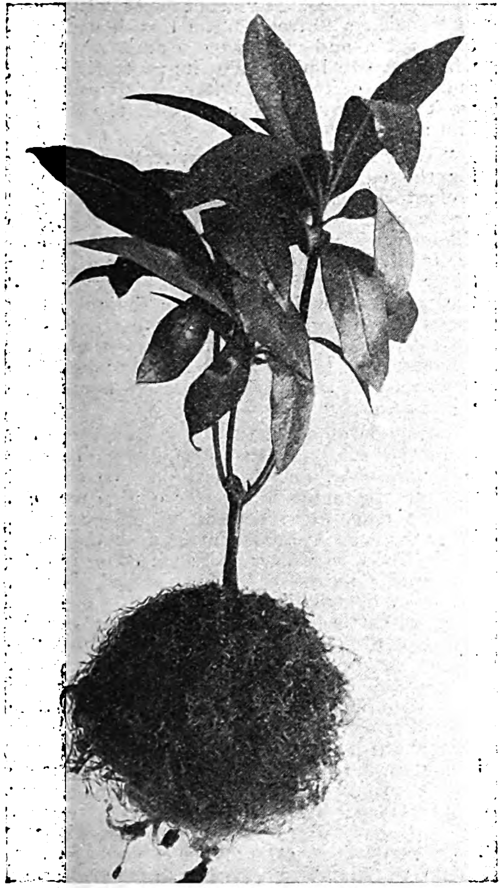

FIG. 54.—RHODODENDRON OCCIDENTALE HYB. Inserted June, 1928; photographed January, 1929.

The next group consists of plants which are more vigorous in habit, possessing larger leaves, belonging botanically to various series and embracing many of our finest early-flowering Rhododendrons, viz., R. praecox, R. emascalum, R. Rosy Bell, R. racemosum and R. spinuliferum, besides many of the free-flowering members of the Triflorum group, such as R. yunnanense and R. chartophyllum forma praecox. Of these, it is essential that the hybrids, such as R. praecox and R. Rosy Bell, be raised vegetatively, and it is a curious fact that any Rhododendrons possessing, as these two do, R. ciliatum blood, are particularly easy to raise from cuttings.

The cuttings should be about three inches in length and of the current year's wood, with a slight heel, and inserted in a warm frame in a mixture of peat-moss litter and sand, in late June or July, where they will produce sufficient roots to be ready for potting up in from four to six weeks. Although not so necessary with the evergreen plants in this group, it is essential that the deciduous kinds, such as R. emascalum, R. mucronulatum and R. praecox, should be ready for potting sufficiently early to enable them to make new growth before the ensuing winter approaches; I always endeavour to keep them growing until December.

It is, however, the large-leaved evergreen Rhododendrons that are most difficult to raise from cuttings, and it is with particular reference to these that I write these notes. A few years ago, I rooted, with great success, a large batch of cuttings of R. Cunningham's White (Fig. 41, p. 79), a very useful old hybrid dating from 1830, which possesses R. caucasicum blood.

On October 1, 1928, I made up a warm frame of peat-moss litter and sand, which was kept at a temperature of about 65°. to 70°, and decided to fill it with a representative set of hybrids and varieties possessing R. caucasicum blood. Batches of the following were inserted: R. caucasicum var. pictum, R. Cunningham's White, R. Cunningham's Sulphur, R. Nobleanum (Fig. 55), R. Nobleanum var. venustum, and R. Rosa-Mundi. The wood selected for cuttings was that of the current year's shoots, about three to six inches long, and made at the junction of the current and previous years' growth. Early October was selected as the best time for insertion, with the idea that the cuttings would produce roots during the winter, and therefore have a very long growing season ahead in 1929.

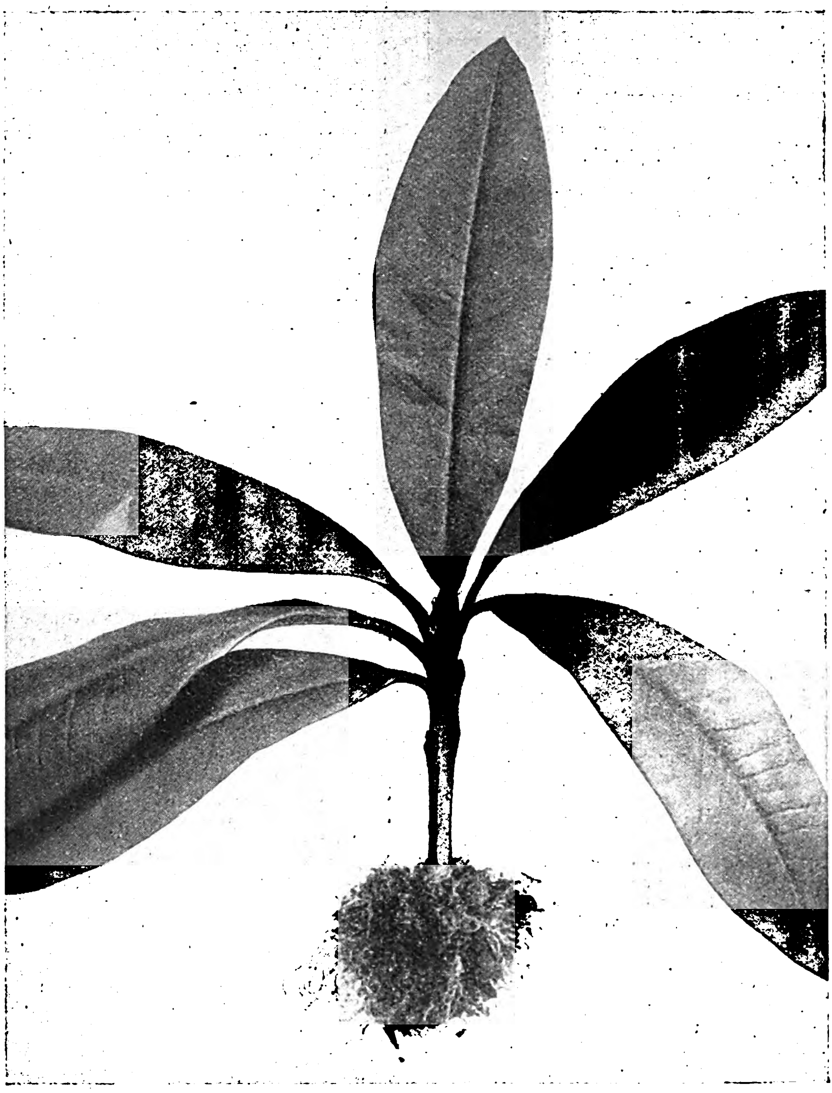

FIG. 55.—RHODODENDRON NOBLEANUM. Inserted October 1, 1928; photographed January 14, 1929.

On January 14, 1929, these cuttings were examined, with the following results:—There were ready for potting-up, over ninety per cent. of R. Cunningham's White; about eighty per cent. of R. caucasicum var. pictum; fifty per cent. of R. Rosa-Mundi; and a smaller percentage of the others, with the exception of R. Cunningham's Sulphur, where a few of the cuttings had rooted but not sufficiently to pot up.

Inserted at the same time was a batch of a typical hybrid Rhododendron, viz., R. Isabella Mangles, but up to the time of writing none has produced roots.

The conclusions arrived at are that Rhododendrons possessing R. caucasicum blood may be raised from cuttings; and the further behaviour of the plants already raised will be watched with interest. R. Cunningham's White, I may add, has already proved itself and grows away quite freely, producing flowers at a very early age. The propagation of the Azalea division of the genus by cuttings should be tried more frequently as, too often, one sees Azalea gardens ruined by the suckers of the stocks outgrowing the varieties grafted upon them.

Cuttings of Azaleas inserted in June, so soon as the wood becomes firm enough to handle easily, will root quite successfully. They should be made about three inches long, with a slight heel of older wood, and inserted in a mixture of peat-moss litter and sand, with a temperature of about 75°.

The great point in successfully raising Azaleas from cuttings is to get the young plants into growth the same summer as the cuttings are inserted; if they are inserted in June, they may be potted up in July, and will continue growing until December, and, after a short rest, should start into growth again early in the New Year. (See Fig. 54: R. occidentale hybrid, inserted June, 1928, photographed January, 1929). For the first few years, Azaleas raised from cuttings are inclined to grow slowly, but they eventually form shapely, free-flowering bushes.

The Kurume Azaleas and obtusum varieties are very easily raised in the same way as the above, and will produce very good flowering plants in from three to four years.

Among Rhododendrons, in addition to those already mentioned, which have been successfully raised from cuttings, are R. Augustinii, R. Broughtonii var. aureum, R. Chapmanii, R. hypolepidotum, R. moupinense, R. repens, R. virgatum, R. Williamsianum, and, of course the race of warm greenhouse plants commonly called the Javanese hybrids. A clerical error occurred in my previous notes; the title under Fig. 39 belongs to Fig. 40, and *vice versa*. *F. P. Knight, Royal Botanic Gardens, Kew.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar.* 7818.

AN ATTRACTIVE EVERGREEN.

I AM prepared, in spite of the discredit of the archaeologist, to speak a good word for the Ivy. True, it has been charged with the habits and vices of a vampire, and accused of battening on the blood of aged and decrepit buildings. But it is equally true that it has kept off the death-sweat from another, and absorbed the damp which threatened to make it crumble and decay. It is said to force its rootlets into the joints and marrow, and loosen the members, but has it not also bonded the skeleton together, and prevented the bones of an old castle, or the stones of an ancient abbey, from falling apart? It is accused of garrotting the very tree by whose friendly aid it has climbed to eminence, but has it not beautified the unsightly, and thrown the green mantle of its polished foliage over many an uncomely thing, and made it an object of delight? Concerning the Ivy, it may be said that a good quality may be set over against every doubtful character, and a tribute may be paid to its virtues whenever its vices are held up to scorn.

I find its leading and most conspicuous virtue in its flowers. These are so little-known to many people that my choice may be regarded as a freak. The flowers which are most sought after are showy; they come in spring and summer, flourish in the sunshine, lend themselves to arrangement and display, and win us by their familiarity. The Ivy, on the other hand, is coy. It blooms in winter when other blossoms are rare, often continuing in perfection from October or November through the festive season of Christmas, and well into the New Year. The flowers yield much welcome nectar, and by spreading over the warm side of some neglected wall, as Knapp long ago remarked, or overtopping some sturdy hedgerow, the sunny bark of the broad Ash or the rugged cortex of the Oak, provide a universal banquet for the insect race: "The great black fly and its numerous tribe, with multitudes of small-winged creatures, resort to them; and there we see those beautiful insects, the latest birth of the year, the Admiral and the Peacock butterflies, hanging with expanded wings like open flowers themselves, enjoying the sunny gleam, and feeding on the sweet liquor that distils from the nectary of this plant." And this at a time when fare is hard to find, and starvation looks the insects in the face.

Another peculiarity of the Ivy is that it refuses to spend thought on its reproduction so long as it has work to do for others. Has it never struck the reader that the plant begins to blossom only when it can no longer climb? Plant it by an unsightly wall or cause it to grow near an ugly stump or ancient ruin, and it will work assiduously to cover them over with beauty; but the years may come and go, and the seasons for flowering and fruiting may pass, without ever turning it from its task, or causing it to turn aside from the path of duty to serve its own ends. Is it any wonder that our modest evergreen has from time immemorial stood as the symbol of a generous friendship and an unwavering fidelity? "Thus does it attach itself even to the destitute; and when death has smitten its protector, it again restores him to the honour of the forest; when he no longer lives it causes him to revive, by decorating his pallid branches with garlands of flowers and festoons of perennial verdure."

In the next place, I may remark on the happy way in which the plant introduces variety, which is another term for beauty and charm, into its effects, by modifying the contour of its leaves. Let anyone pluck a series of these and trace their outlines. The variation is marked in many ways. Those leaves which are near the ground will probably prove dissimilar from those which are on the rambling shoots, and those again which surround the clusters of flowers and fruits will differ from the rest. The shapes are rarely duplicated, and the venation resembles the streams which meander at their own sweet will through meads which they render green and fertile.

Or shall I dwell on the appeal which the Ivy makes to us by reason of its bearing rich clusters of purple-black fruits at a season when all other dessert for the birds is at a premium, and when many would have to go without a dinner but for the timely provision which this forethought secures for them? It is not the friend who offers us aid in days of plenty, so much as the one who succours us in the hour of need that wins our deepest affection. A brother is born for adversity, and a friend loveth us even in the winter of our discontent. And the Ivy is like these.

It has often been remarked that there are at least two sides to every question. One side is expressed by a now forgotten poet—Langhorn—who wrote somewhat malevolently that—

> "No flower can bear the Ivy's shade,
> No tree support its cold embrace."

It may readily be conceded that it is injurious to young growing timber by reason of the check which its clasp imposes on its expansion, and by sapping the soil of nutriment, but it will also be agreed that if the Ivy were subjected to less general persecution great benefit might ensue to the agriculturist and sportsman.

The Ivy is not a parasite as many suppose; parasites are those which live on pabulum prepared by others for their own nutriment. Parasites cannot produce green leaves or manufacture chlorophyll. Closely as the Ivy may embrace the Oak, its rootlets do not sap the energies of the tree, or its claspers suck its blood. It flourishes on a wall which can afford it no nourishment, and if the plant which climbs about a tree is cut or injured it dies, which it would not necessarily do if it were able to gain a livelihood either in whole or part from its supporter. It may be stated of the Ivy, it recompenses the strength it borrows with the grace it lends, and recalls the spouse in the Canticles leaning on the arm of her beloved.

The Ivy was known to the Roman Pliny, who tells us that at his seat in Tuscany the trunks of his Plane trees were entwined with it in such a way that they were often roped together. This beautiful habit of throwing out trailing shoots has led to the plant being used in some places for hedges, after the manner of the Smilax or Sarsaparilla. It is specially useful for covering trellis work in spots where other plants refuse to grow. Plots of ground in the neighbourhood of buildings and factories which would otherwise be unsightly may be rendered beautiful by adopting the hint first given, I believe, by Curtis. "Few people," he remarked many years ago, "are acquainted with the beauty of Ivy when suffered to run up a stake, and at length to form itself into a standard; the singular complication of its branches, and the vivid hue of its leaves, give it one of the first places among evergreens." I have seen it so employed in the Black Country, and in the neighbourhood of manufacturing cities, with splendid effect, and wonder that the custom of growing it thus is not adopted more widely.

A further plea for the Ivy may be based on the fact that it is much favoured by the birds. The habit of its leaves enables them so to droop and arrange themselves that a nest may be completely hidden from view, and I have often had the joy of seeing a young brood safely brought up in such a nursery. The thrush and blackbird, robin and sparrow are among the birds which love to build under its protecting shade, and the editor of Withering's well-known work on botany supplies us with the following hint:

"We would suggest (he writes) as a motive for the cultivation of the Ivy to those who prefer to a cheerless, death-like silence the vocal grotto animated with life and enjoyment that the shelter it affords from wintry storms, the berries as food during the most inclement seasons (since they remain uninjured by frosts), and the covert in which to secrete their nests and rear their young, prove most attractive to the feathered race, and will often reverberate the soft cooing of the dove, the mellow notes of the thrush, and the varied trill of innumerable minor songsters."

It may be objected to the cultivation of this attractive evergreen that its foliage is nauseous and poisonous, and therefore to be eschewed where cattle, ovine, bovine or equine are kept. This is true, more or less, of all evergreens. Were they usually toothsome morsels they would be devoured in winter and soon cease to exist. Hence this means of self-preservation. It is, however, a striking fact that while one often hears of cattle being poisoned by the Yew and other plants, it is a rare thing to learn that injury has been sustained through eating Ivy. Some very interesting facts have been placed on record in this connection, and from these the following may be particularly noted. Horses and sheep eat the foliage without suffering injury, although cows and goats usually refuse it. It has been stated that sheep seem to prefer Ivy to grass in the winter, devouring it eagerly, while deer will also feed upon it. Some farmers have been wont to strip off the leaves as food for cattle when fodder is scarce, and even cows may then be induced to eat it. I think I have said enough to justify my title, and prove the Ivy an attractive evergreen. *Hilderic Friend.*

THE ALPINE LAWN.

THE article of Mr. T. Hay, in the issue of *The Gardeners' Chronicle* for December 22, 1928 (p. 491), on the "Camomile Lawn," followed by notes on the same subject by Mr. J. Comber and Mr. J. Fraser, in the issue for January 5 (p. 15), provide interesting suggestions and open up great possibilities for the variation of the composition and function of the lawn as it is known to-day. Doubtless, the grass lawn for the purposes of games cannot be improved upon, other than, perhaps, by the introduction of Camomile; but scent is ever a pleasing and intriguing character, and the list of plants given by Mr. Comber suggests a means whereby the ornamental grass lawn may be made to possess the added charm of fragrance, and the list may be extended to include many other sweetly-scented, low-growing herbs.

And this leads us to the consideration of what, for lack of a better name, may be termed the alpine lawn, the formation of which embraces untold possibilities. I think it was Mr. Clarence Elliott who first advocated this form of alpine garden, and it is, in my opinion, a distinct improvement on the alpine meadow for, whereas the grass on the latter has to be cut by midsummer, and the meadow is thereby shorn of most of its beauty, the alpine lawn, being composed of judiciously selected, prostrate, or low-growing plants—many of them scented—does not call for such harsh treatment, and may be so formed as to continue attractive throughout the year.

If the site selected for it, whether large or limited in dimensions, is undulating, or, better still, sloping gently down to ground kept moist by a small stream or pool, planted with low-growing, moisture-loving plants, such as the richly-coloured Oxycoccus macrocarpus, and the lovely Saxifraga granulata, together with its double form, also the double-flowered Cardamine pratensis fl. pl., the possibilities of producing a charming effect are enhanced considerably.

Then again, the alpine lawn need not be flat-surfaced, for, naturally, boulders should jut out here and there, and occasionally there may be clumps of taller-growing subjects, together with a few appropriate shrubs. The soil beneath the latter may be carpeted with such subjects as the dainty foliaged Cotulas—notably C. squalida,—Helichrysum trinervatum, and possibly the humble Linnaea borealis, which are partial to shade.

Among the subjects most suitable for forming the alpine lawn, the various forms of Thymus Serpyllum take pride of place, for they naturally form close carpets, are rapid in growth, and attractive both in flower and foliage, and have the added charm of fragrance, which is released when the plants are trodden under foot. The Camomile might well be employed, and another native plant which suggests itself is the Milk-weed, Polygala calcarea, abundant on the chalk hills of Surrey, which forms a close mat of deep green foliage, and produces small inflorescences in varying shades of colour, from almost pure white to deep bluish-purple. Associated with this subject in its natural habitat is the dainty little annual Linum catharticum, with tiny white blooms, and once this has been established it will appear with unfailing regularity each year. The Antennarias immediately suggest themselves for furnishing the alpine lawn, as do the low-growing Achilleas, especially the oft-praised A. × Lewisii, for the production of flowers late into the summer. There are several Acaenas, notably A. Sanquisorbae, which might be used to produce a variety of colour effects, while many of the Campanulas lend themselves admirably to this form of culture, and such alpine Pinks as Dianthus deltoides, in its several varieties, may also be included. The low-growing Potentillas, Dryas octopetala, several of the Androsaces, Globularias, Douglasia Vitaliana and Silene acaulis, are but a few of the subjects worthy of consideration when a selection of plants for the alpine lawn is being made.

The general arrangement of the plants requires careful consideration, for, naturally, many of the plants enumerated above are much stronger-growing than the others, and while the former may be allowed to merge together, they should be so arranged as not to smother the less vigorous sorts.

So the original conception of the alpine lawn, as it is termed, may be greatly improved upon. Gentians may be introduced, for many of them, especially G. verna, we are informed, are naturally found growing in conjunction with other prostrate subjects, while it is also suggested that some of the difficult Primulas might be grown with better prospects of success under the conditions embodied in the alpine lawn, provided, of course, their associates are specially selected and not likely to prove overpowering.

Again, there is the question of introducing bulbous subjects, of which there are many which might be employed. At the summit of the slope, where it is warm and dry, the bright crimson Anomatheca cruenta might be planted beneath subjects of not too matted growth, while the Hyacinths, Chionodoxas, Muscaris, Crocuses, both spring- and autumn-flowering, bulbous Irises, notably Iris reticulata; miniature Narcissi; Scillas and, possibly, Tulipa species, are a host in themselves, all suitable for associating with carpet plants, which will form mattresses for the blooms when they are beaten to the ground by rain, and so prevent their beauty being marred.

So it may be seen, from the meagre suggestions given above, that the alpine lawn embraces great possibilities as a charming feature of the garden, while the labour required for its upkeep, once it has been established, is inconsiderable, as it will need very little attention for a number of years, if cleaned over annually and occasionally top-dressed with good compost, care being taken not to allow strong-growing weeds to establish themselves. *M. W.*

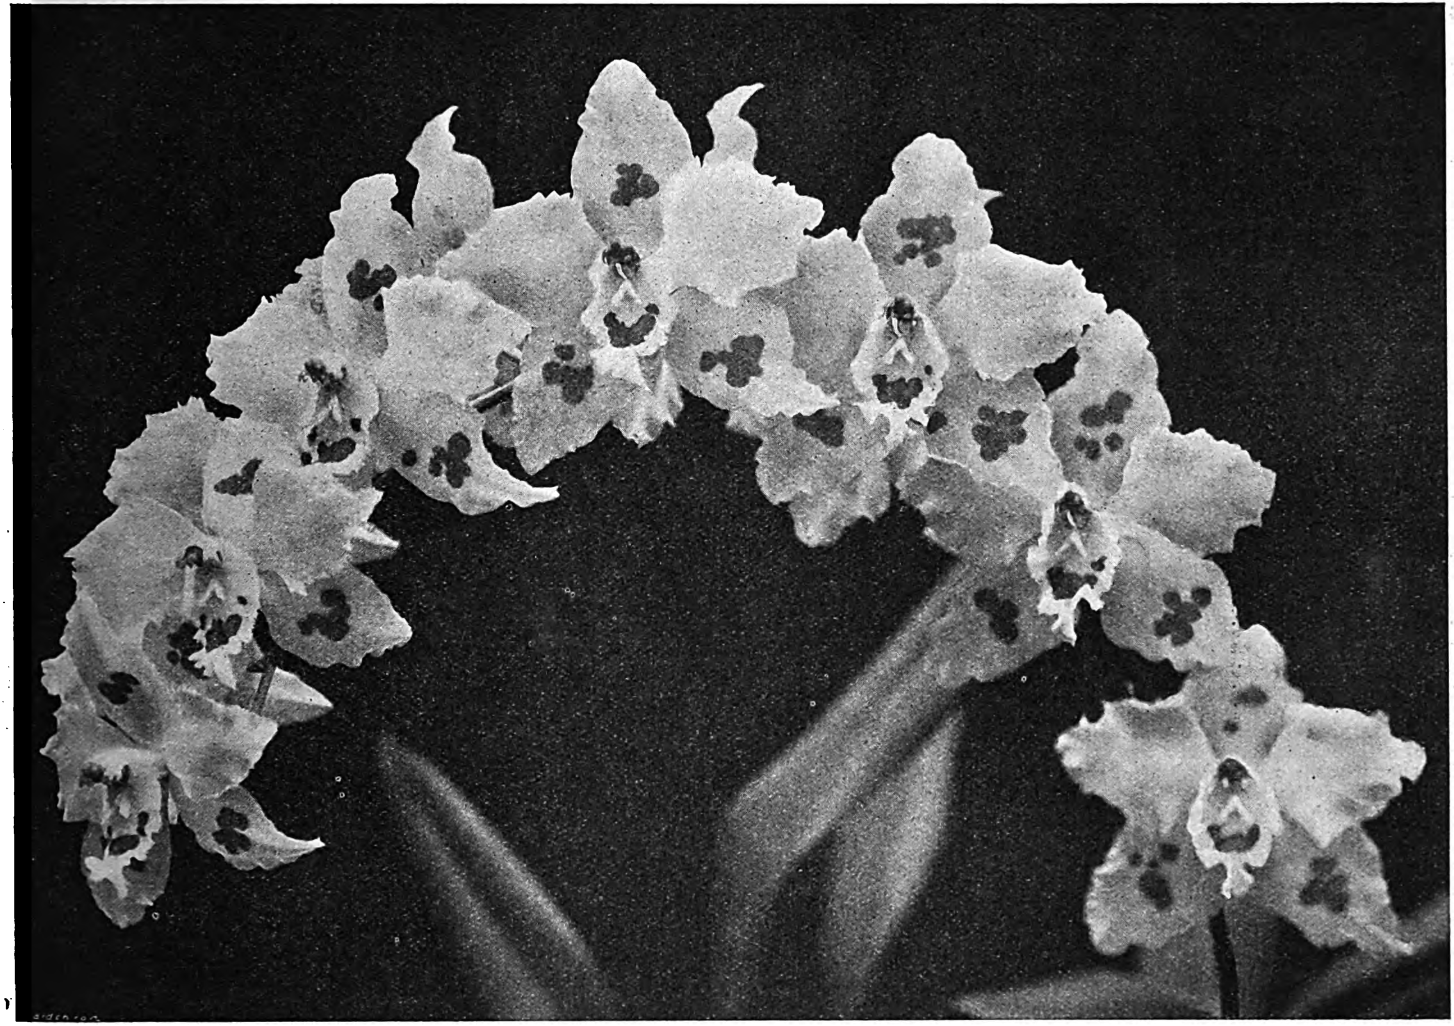

FIG. 56—ODONTOGLOSSUM MIRUM VAR. AUREUM.

R.H.S. Award of Merit, January 29. Flowers pale yellow and brown. Shown by Messrs. J. and A. McBean.

(see p. 89.)

FLORISTS' FLOWERS.

BORDER CARNATIONS.

Now that the border Carnation is definitely coming into its own again, as evidenced by the increased number of firms specialising in these flowers, many interesting points about their cultivation, and the manner and treatment in regard to setting up blooms for exhibition, are being discussed. Although there is practically little new to learn from a cultivator's point of view, as compared with what was practised by the past generation of Carnationists who made possible the wonderful varieties of to-day, the rules which govern the show-board have been materially altered and modified, chiefly because open border cultivation is more general, so that classes for such flowers and also for seedlings, are now included in all schedules; but it is only during the past half-dozen seasons or so that amateurs have been able to compete in this manner at the big London show, all exhibits having previously been grown entirely in pots, and flowered under glass.

Now, while we undoubtedly get the perfect bloom from pot culture, as it is sheltered from all adverse conditions, in setting up we are allowed wire and, although not allowed—perceptibly—we also get that bane of all Carnation lovers, the dressed flower, which all who have the best interests of the Carnation at heart are endeavouring to abolish.

This, however, presents many difficulties, for even if an authorised person were told off to disqualify any exhibitor seen dressing his or her blooms, it would not necessarily stop the evil, as the operation could be performed previously, and certainly would be by anyone who follows the practice, regardless of the fact that it is forbidden. In such case, even if it were pointed out that the blooms looked perceptibly dressed and the exhibitor denied the "use of artful aids," what then? No one could prove it, and his word must be taken, although there be ocular evidence to the contrary.

It is a most unsatisfactory state of affairs, as the exhibitor who has set up his flowers in a bona fide way—everyone being allowed to straighten petals, or remove a small, deformed or superfluous petal, which will sometimes occur in the centre of an otherwise perfect bloom—has no chance whatever against one who is an adept at dressing, and whose blooms in their true form are inferior to those from which he now wrests the prize under conditions which he knows to be wrong.

Anyone who has watched the process of dressing knows that a flower can be made so totally unlike its original shape as to be almost unbelievable, and where the advantage comes in the long run it is hard to see, and, indeed, it is obviously a drawback to growers and raisers alike, for even if a variety has good form in its true shape, it may not be the form which is admired by the amateur who sees it for the first time at a show, in its dressed fashion, which makes all the petals (so many as have been allowed to remain) lie perfectly flat; and although some lovely varieties now in commerce do grow naturally in this manner, they are the exception and not the rule, the majority having smaller petals which make a centre, or crown. Anyone purchasing a variety on its form as a dressed bloom may be quite out of conceit with it when, on flowering, it is found to be of a totally different shape, however admirable. It is not the form expected, and is very often discarded as being not true to type. It is therefore certainly to the advantage of all Carnation specialists that setting-up should be done without that pernicious use of the tweezers, which, after having almost pulled the petals out of the sheath to effect the desired end, leaves the flower an absolute wreck at the end of the day.

I am quite aware that the old florists considered dressing not only permissible, but that it added to the beauty of the flower, and many of them derided the amateur who, even then, objected to it, saying that it was his want of skill in the art that made him wish to abolish it. This, however, does not alter the fact that if a bloom has run, curled or deformed petals, which have to be removed, besides an indifferent shape which has to be adjusted to render it fit to meet the judge's eye, it is certainly not a flower which should ever have been set up as representing the form of that variety.

It is here that open border classes prove so desirable and necessary, as displaying true form without wires or other manipulation; although the blooms may not be quite so unblemished as those from under glass, even if protected to a certain extent by caps just before show time—which is allowable.

It would be much better to resort to the dressed blooms on cards—now discarded as a separate class—if it is desired to show how much more admirable is the artificial, hand-made bloom than the natural, and beautiful flower which, when well grown, cannot be improved, only altered.

As regards varieties, there have been very few Yellow-ground Fancies of outstanding merit in the past few seasons, probably due to the fact that this beautiful class greatly predominated for some time, and raisers simultaneously seemed to turn their attention to the White Grounds and Fancies proper, while some have set themselves a standard of excellence in this respect, and until that is reached all flowers are discarded, without any appeal to the show-board.

One well-known amateur raiser, whose seedlings are marvels as to colour combinations, is not satisfied because he cannot get the strength as well as the colouring in the "exotic" varieties which he favours, and, indeed, considers the only ones worth raising. From his point of view this is understandable, as the fine varieties sent out must necessarily be strong, and unique beauty does not always possess this quality, although with time and patience, he hopes to achieve his end. He has a wonderful flower which I hope to see this season, the description of the colouring being totally unlike any other, but one can only trust it will have all the other qualities which go to make a perfect border variety.

While it is the aim of every raiser to cultivate and send out only varieties which have the strong and rigid stem that would enormously add to the popularity of the border Carnation, one could not, on that account, discard all the varieties at present in commerce which decidedly do not possess this attribute, or even a strong habit of growth, for it is very doubtful, to my mind, if the Yellow-ground Fancy, in all its combinations of colouring, would ever be equal in all respects. Take the varieties in which orange and heliotrope predominate, or in which these colours are associated with apricot shades; these are never associated with strong habit, and almost invariably they belong to what is generally called the exotic class, and give their best only when grown under glass, for exhibition. The same may be stated of most Selfs in these colours: Brindle, heliotrope, and Purple Emperor being the only two consistently good with me in the border, while Dr. R. Crawford and Effie Deans, apricot, have usually given good blooms and layered well—not always a satisfactory operation in varieties ranging from orange downwards, except a clear yellow, which likes a somewhat heavier medium, in my experience.

We should all welcome a new, good yellow Self, the blooms exhibited being often restricted to one variety shown by all exhibitors, and very seldom do we see more than two, which shows how few yellow sorts sent out during the past half-dozen seasons have proved good enough to be regarded as standard varieties; this is to be deplored, as no flower is more decorative and lovely than a sulphur-coloured Self.

Now that so many amateurs grow Carnations solely in the open border, and whose number is greatly on the increase, it has been suggested that the standard of excellence necessary at present, in the border Carnation, should be modified, or that there should even be two standards of excellence, so as to include some of the varieties which, although good in regard to other points, have fimbriated petals. I fail to see what advantage this would be, for if exhibits of both smooth-edged and fimbriated varieties were shown in the same classes, it stands to reason that the former would win in every case, therefore, to benefit exhibitors with fimbriated blooms, a separate class would have to be included in the schedule—rather a remote possibility when one remembers that the glory of the border Carnation is its smooth edge, and also the aim and end of every raiser, past and present.

I am quite certain also that every amateur, as he grows in knowledge of the flower, would discard fimbriated blooms from an exhibitor's point of view, in favour of the perfectly-formed varieties; but surely it is not necessary to only have the show-board in mind when cultivating these lovely subjects. For garden decoration and cutting there are many beautiful varieties which, although, perhaps, not quite perfect in form, have stiff stems, strong habit, and are usually more floriferous than those regarded as exhibition sorts; these make large plants, if left unlayered, and these are the only points that need count where display is the first consideration. Vesuvius, the scarlet Self, is an excellent example in these respects, but I must leave any further mention of varieties for a future article. *J. B. Wells.*

EARLY-FLOWERING CHRYSANTHEMUMS.

Further trials of early-flowering Chrysanthemums were carried out in the Horticultural Department of the Cheshire School of Agriculture in 1928, under conditions typical of north-western England.

All new varieties which could be obtained were included in the trial conducted this year in the North Garden, and all were grown under similar conditions.

In every case a certain number of plants were grown disbudded, and the remainder naturally, as sprays. Beds were prepared twelve feet by four feet six inches, and the plants were set eighteen inches apart. Planting was carried out during the first week in May. During the season, notable for its dry weather conditions, all varieties made very good progress except Peerless, which failed altogether. The flowering period this year was normal.

Unusually early and severe frosts were experienced on September 30 and October 1 (10° and 13° respectively of frost being registered). All varieties were severely injured, and although some recovered and ultimately flowered well, others made very imperfect recovery. Many varieties in last year's trials are now grown in our commercial section; some have been discarded as useless, and others have been included again this year in order to determine finally their value. Raisers of new varieties desirous of participating in future trials are invited to communicate with the writer.

Observations on the varieties included in the trial are as follows:—

Afterglow.—Terra-cotta, does not disbud well; not a particularly robust grower.

A. E. Cooper.—Bright bronze, tipped with gold; one of the strongest growers in the trials; large early blooms; disbuds well. A variety with a commercial future.

Border Beauty.—Amber-buff, dark centre; grown for a second year in the trial, it again failed to respond well to disbudding. It is, however, a beautiful September variety in Cheshire, and is upright and firm in its growth. A garden flower rather than of commercial value.

Claret Gold.—A fairly strong grower, but of indefinite colour. It produces a number of blooms with open centres. Not recommended.

Chestnut.—This variety was too late this year owing to the frost. It is, however, a suitable type for bunching as sprays; rather tall.

Daffodil.—Of Goldfinder type; as its name implies, it is yellow in colour, and judging from one year's trial, will prove to be a good market variety. A very strong grower, disbuds very well.

Edna Foulkes.—A yellow, September-flowering variety; its appearance suggests a sport from September White, of which there are several already in cultivation.

Frederick Smith.—Pink, with gold points; early-flowering, of robust growth. Disbuds well, and is worthy of further trial. Probably a good commercial variety.

Godfrey's Early.—A very free-growing yellow variety with incurved petals; disbuds well; withstands wet weather particularly well and appears likely to become a great favourite.

Glow.—Bright reddish-bronze; a free-growing, sturdy variety; disbuds well and gives a fair-sized bloom. It is a variety that certainly deserves to be better known.

Hesperus.—Resembles in every respect Chestnut, with which it is probably synonymous.

Jacky.—A very pleasing pink; an excellent selling colour; disbuds well; flowers of moderate size; a good variety for spray work; it has stiff stems.

Jack Robbins.—Golden-yellow; not so early in the trial as Bronze Early Buttercup; petals slightly incurved and of good substance.

Mrs. James Scalley.—Rose-pink; a strong grower and of compact habit. An October variety in Cheshire, and cut down this year by frost. Will certainly be tried again.

Janet Wyper.—A good creamy-white variety; excellent as a spray; very long stems. To be recommended as a cut flower.

Mayford Bronze.—Bright orange-bronze; early, of good habit and disbuds well; leaves small. Certainly worthy of extended trial.

Madeline.—Pale yellow; on our soil it failed to make strong growth. An early flowering sort, but the blooms are small, on weak, spindly, brittle stems that are easily broken by wind.

Mrs. E. Cartwright.—Crushed-strawberry colour, two-and-a-half feet in height. A very useful spray variety, but not so popular on the market as expected last year. May be disbudded.

Mrs. J. Whitehouse.—Crimson, with gold reverse; incurved petals. Of Hotspur type. Grows very well in our soil and disbuds well, producing incurved flowers in September.

Periscope.—A Single, upright, yellow variety. Rather disappointing this year, as the flowers were affected by rain; three feet in height.

Peerless.—A poor type of Single, yellow, that came to us badly affected with eelworm, and failed to make any progress.

Pinkest.—Soft pink, free-growing; rather late in flowering; cut by frost before fully opening.

Pink Dame.—Very beautiful soft pink. A very early-flowering variety. Good for spray work.

Purple Robe.—A distinct shade of purple (not popular with local florists); weak in growth; two-and-a-half feet in height.

Radio.—A distinct shade of orange-yellow; strong grower and of compact habit. Disbuds well; blooms rather late in September, and was damaged by frost in these trials.

Ronnie.—Deep golden-yellow; very compact, sturdy grower, suitable for border decoration, flowering in early September; of moderate size when disbudded.

Richard Holding.—Very bright bronze-red. An early September Single that continues until cut by frost; of good habit and growth; bunches well.

Shirley Fawn.—Not a success; growth very weakly; colour too undecided for either border decoration or commercial work.

Shirley Bronze.—A weak grower, not recommended for the north. (We gave this variety a similar report last year.)

Tango.—Terra-cotta; a strong-growing variety. Disbuds well and bears a good-sized bloom; rather late and damaged by frost.

Miss B. Brookfield.—A local variety not yet in commerce. (Sent in for trial by Mr. F. Harding, of Poole, near Nantwich.) A golden-yellow Single; two-and-a-half to three feet in height; has strong, healthy foliage which is not too large and does not overcrowd. Sprays of six to ten blooms nicely placed on two-feet stems. A very good packer and "keeper."

All remarks regarding colour and growth apply equally to the requirements of the private gardener and the commercial grower. This yearly report always brings me letters of thanks, advice and help, and to those who have written, giving me helpful suggestions, I am grateful.

I must again thank the County Council Head Gardener, Mr. P. Shaw, M.M., on whom the great burden of the work in connection with these trials has fallen, for his constant care and attention, and for his continued interest. *W. E. Shewell-Cooper, C.D.H., Horticultural Superintendent, Cheshire School of Agriculture, Reaseheath.*

NOTES FROM WISLEY.

That there is much of interest to be seen in the gardens of the Royal Horticultural Society even in the winter months is amply evident to the visitor, for at the entrance itself several pleasing features are at once noticeable; in particular some seedlings of Berberis Wilsonae, which hang over the wall, and whose coral fruits, having so far escaped lightly from injuries by birds and the weather, harmonise well with the red brick-work. Flowers are also provided by Iris unguicularis which, although planted quite recently, is flowering freely against the wall of the laboratory. In addition to features of botanical interest to be seen at the entrance, a great improvement has been effected by the removal of the temporary arrangements for the signing of the visitors' book, and by the substitution of a new and permanent shelter in keeping with the style of building.

Throughout the gardens, everything is very behindhand, and little is to be seen in flower in the wild garden or the rock garden. The severity of the weathor has, however, intensified the colour of many of those subjects whose leaves are conspicuously coloured during the winter, and many good effects are to be seen. Among the most decorative are the crimson leaves of Saxifraga Beesiana. The leaves of Saxifraga Geum are also noticeable for their purple reverse, while those of Galax aphylla are conspicuous on account of their red colour. Another plant which stands out at this time of year is Polygonum affine, the dead leaves of which are persistent and remain bright brown throughout the winter. Similarly, few plants are in bloom in the alpine house, and much of the colour is provided by the Stonecrops with bright-hued foliage, such as Sedum spathulifolium var. William Pascoe, which has mauve leaves; Sedum Stahlii, with red and brown leaves; and a form of Sedum dasyphyllum, in the foliage of which delicate shades of pink, mauve and green are visible.

A few Saxifrage hybrids, mostly of the Kabschia group, are beginning to show bud, notably Saxifraga Kellereri, the early-flowering S. Burseriana tridentina, S. × Elysium, and S. × Brenda, both with rose-pink flowers. One of the few plants which, as yet, appears to be flowering with any degree of zest is the cheerful little Mediterranean Cress, Morisia hypogaea, with its bright yellow flowers and rosette of deep green leaves. A large pan in the alpine house which seems to present what one may almost term a comic appearance, contains one of the Cobweb Houseleeks which is covered with hundreds of extremely small rosettes.

A new Cistus bed is being formed in close proximity to the existing collection of Helianthemums and should afford a good means for a comparison of the different varieties and of their hardiness. The collection of Paeonies at Wisley has been replanted, and now occupies an extremely imposing area which will be interesting when the plants are in flower, and again in the autumn on account of the tinted foliage, but which seems likely to be devoid of attraction for a considerable portion of the year, unless supplementary flowers are planted with them.

In the wild garden, Hamamelis mollis is, as usual, flowering well and diffusing its pleasant fragrance, while the buds on the Azaleas are swelling and promise, with favourable weather conditions, a very good show of bloom this spring.

Among the Heaths, Erica lusitanica is now in full bloom, and many others, such as E. carnea, E. darleyensis and forms of E. mediterranea, such as Brightness, are fast coming into flower. Although any tendency towards variegation would seem out of place in the natural effect sought in a Heath garden, the golden form of the common Ling is undoubtedly a handsome plant, and particularly so at the present time, at which its golden foliage is tinged with red. A golden tinge is also perceptible in the new growth of Bruckenthalia spiculifolia and also in that of Erica arborea alpina, plants of which, although planted not so long ago, have already reached a height of about six feet.

Around the field-garden pond the bright-stemmed Willows and Dogwoods do much to relieve the wintry appearance of this part of the gardens, but they are by no means the only plants which are ornamental in this way. Certain Barberries, such as Berberis Jamesiana and B. yunnanensis, possess long, scarlet stems, while red shoots are also a feature of Coriaria myrtifolia and of the pigmy Viburnum Opulus nanum. The deep crimson, brush-like fruits of Rhus typhina are still to be seen on the pond bank, and Myrica carolinensis still retains a few of its fragrant leaves. *J. E. Grant White.*

TREES AND SHRUBS.

ESCALLONIA PTEROCLADON.

This is a shrub which seems to remain in comparative obscurity, no doubt owing to the popularity of its relatives, notably E. langleyensis, E. Donard Seedling, etc. Nevertheless, it well merits a place in the shrub border, not only for the thickly-clustered white flowers, but also for the pleasant contrast during the winter months between its reddish-brown bark and dark, evergreen leaves.

It attains a height of from six to eight feet, growing strongly erect, with no tendency to droop, as have the above-mentioned kinds; the bark on the younger branches is winged, from whence arises the specific name; in maturing, the bark peels off in strips or flakes to produce the reddish effect. The leaves, varying from one-half- to one inch in length, are oblong-oval in shape, tapering sharply towards the base, while the margin is serrate. The flowers, which appear about the end of July, droop evenly along one side of the short branchlets, which they clothe from end to end, so that although the individual blooms are small, a bush in full flower is extremely effective.

I was surprised to see a young plant of this species, which had not previously flowered, producing many sprays of blossom in November and December last, in a position which was in no way sheltered. It is a good example of the hardiness and precocity of this shrub. Propagation may be effected without difficulty by means of cuttings taken during late autumn; these may be rooted in a cold frame, and the young plants grow quickly when planted out in their permanent position.

E. pterocladon was introduced by Messrs. Veitch in 1854, through their collector, William Lobb, who sent it home from western Patagonia. It is figured in the *Bot. Mag.*, t. 4827. *B. O. M.*

VITEX AGNUS-CASTUS.

In many parts of southern and eastern Europe this curious shrub is seen very frequently, and a distinctly pleasing object it is with its masses of reddish-violet blossoms. In this country it seldom does really well, but I see no reason why it should not succeed in the south, especially as a wall plant. It is not particularly tender, but needs more sun than we generally get.

V. Agnus-castus, familiarly known as the Chaste Tree, is a deciduous shrub of ten feet or so in height, and a member of the Verbenaceae. The opposite leaves are palmate, with five to seven narrow, pointed leaflets; they are rich green, with paler, greyish undersides, and in common with all other parts of the shrub, they possess a refreshing aromatic fragrance. The flowers appear in late summer or early autumn in whorled racemes, and as these are sometimes so much as six inches long, and are borne at the leaf-axils as well as the extremities of the current season's growths, a specimen of this species in full bloom is decidedly attractive and well worth trying to attain. There is also a white variety.

This interesting shrub was introduced from the Mediterranean region so long ago as 1570. There, it generally inhabits the rocky banks of hillside streams, or sea cliffs, and in a natural state shows some variability in the colour of its flowers, which may be almost blue or nearly rose. A broad-leaved form, V. Agnus-castus var. latifolia, found in Sicily, seems to have been in cultivation years ago, but one does not hear anything of it now. It is described as having both bluish-purple and white flowers. *J.*

AKEBIA QUINATA.

This twining plant is worth the consideration of planters of climbing shrubs, for besides having bright, attractive foliage which remains evergreen in mild seasons, its somewhat quaint flowers are deliciously fragrant. This plant is monoecious, the male flowers being of a reddish-purple colour and the female blooms of a chocolate hue, and they are borne profusely on axillary racemes in early spring.

Introduced nearly a century ago from Chusan, A. quinata is not very widely grown, probably because its hardiness is questioned, but although it does not succeed in exposed positions and cold soils, it is much hardier than is usually supposed. When planted in a sheltered position in a sandy loam, with perfect drainage, it is very free-growing, and will soon cover a considerable area and hide unsightly structures with its dainty, palmately divided foliage. The slender stems are produced freely from the base and intertwine immediately on any branches or structure near. If these stems are kept apart and layered, they emit roots freely and thus form a ready means of propagation. *W. A.*

ALPINE GARDEN.

PRATIA ANGULATA.

Among the numerous low-growing subjects which are ideal for carpeting purposes, on the rock garden or in the wild garden, in cool positions, either sunny or partially shaded, is Pratia angulata, a perennial plant of natural creeping habit, from New Zealand, where it is found in the south Island at an altitude of between 2,500 feet and 4,500 feet.

It forms a close mat of prostrate growths, which root as they spread and are clothed with short-petioled, oval, ovate-oblong or orbicular, waved and coarsely-toothed, rather fleshy leaves, which are up to about half-an-inch long, rich green and glabrous above, and often tinged with purple beneath. During the summer the broad mat is studded with small, white, star-like flowers, like miniature Lobelia blooms, borne on short, erect peduncles arising from the axils of the leaves.

P. angulata is hardy in this country, and is easy to accommodate, preferring, possibly, soil inclined to be peaty, although in this respect it is not particular. When once established, it grows rapidly, soon forming a wide carpet. This species is sometimes referred to as Lobelia littoralis, and, like the Lobelia, it belongs to the Natural Order Campanulaceae. *W.*

THREE GOOD MERTENSIAS.

Having given a good many Mertensias a trial, three species have proved much more reliable than most. These are M. virginica (syn. M. pulmonarioides), M. echioides and M. primuloides. The first-named is the Virginia Cowslip, a lovely plant whose only trouble here is slugs. Its broad leaves appear early in spring, and are a cool, emerald green, lightly tinted with a sheen of bronze and blue. Soon after these, the branching, flowering stems rise to a foot or eighteen inches high and terminate in drooping flowers which, from purple buds, develop into a beautiful china-blue, pure and bright. This is a sound perennial and by no means difficult to grow in a deep, well-drained, rich vegetable loam, which does not get too dry. It seems to enjoy partial shade, and the neighbourly companions which afford this will also be useful in warding off spring frosts, from which it is liable to suffer. Once established, this fine plant should be left undisturbed. Since it is herbaceous, entirely disappearing from sight in early autumn, a permanent stake will prevent accidental loss or injury.

Quite as beautiful in its own way is M. primuloides, which comes from the Himalayas. This little three-inch plant has the close, compact habit of a Forget-me-not, to which it bears some resemblance in its oval-pointed, grey-green, hairy leaves, and the shape and size of its blooms. In summer a number of slender flowering growths rise to a few inches above the foliage and unfurl their croziers of blossom over a long period. Like those of most of the Borageworts, these flowers undergo a process of colour-changing as they mature. Commencing in a rosy-purple, they pass into a charming turquoise and azure, and finally deepen into a full-toned violet. A velvety texture affords these generous hues an added richness, which is accentuated by an orange eye. If the effect of a plant in full bloom is somewhat dappled, there is no doubt as to the harmony of the colour blending, and its striking, unusual beauty. Moraine treatment is recommended by many for this choice species, but it will do well in a mixture of sandy peat and gritty loam, with ample depth to ensure uniform moisture. In some rock gardens it thrives surprisingly in the ordinary conditions accorded to alpines in general, and I should not like to be too emphatic as to its requirements. Given sufficient moisture in summer it will enjoy full sun, otherwise some mid-day shade is desirable. Propagation is effected by division or cuttings. One or two very distinct and handsome forms of M. primuloides have been discovered within recent times, but I have not yet seen them in any of the lists.

The other species, M. echioides, is also a Himalayan, and it is easier to grow, in my experience, than the preceding. It makes a similarly low, tufty mat of pale green, downy leaves. In the later summer, branching flower-stems rise above these to a height of about eight inches, and for many weeks maintain a succession of flowers of an intense sapphire-blue. Any good vegetable soil that is cool and moist and well-drained will suit this delightful species, and in such a medium it may have full sun. To increase M. echioides, the means suggested for the preceding may be employed. With both of these, as with the American species, slugs and soil pests must be guarded against. *A. T. J.*

THE GENUS PRIMULA.

(Continued from p. 86).

KAUFMANNIANA (Regel.). Kaufmann's P.
(Cortusoides.)

A downy, perennial species with a tuft of rounded, blunt leaves one to two inches across, deeply or shallowly heart-shaped at the base, borne on slender, downy, or more or less smooth stalks two to three inches long; margins divided into numerous oval, sparsely-toothed lobes. Flower stem six to eight inches tall, moderately downy below, smooth upwards, bearing a many-flowered umbel of rosy-violet blossoms. Corolla about three-quarters-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, about three-quarters-of-an-inch long. Introduced in 1883.

Grows in shady places on the Alexander Mountains in Turkestan, central Asia, at an elevation of 3,000 to 9,000 feet above sea-level.

Culture: Provide it with good loam, leaf-soil and sand, in a cool, shady spot, and protection from damp in winter.

KHASIANA (Balf. f.). Khasia Hills P.
(Candelabra.)

This Indian Primula, which is closely allied to P. prolifera (Wall.), produces several rosettes from the same root-stock, of smooth, non-mealy, lance-shaped, pointed leaves about nine inches long and one-and-a-half inch wide, gradually tapering to an obscure stalk dilated and sheathing at the base; margins slightly toothed; both surfaces covered with pitted glands. Flower stem stout, twelve to eighteen inches tall, bearing one or two umbels of numerous purple flowers. Corolla about three-quarters-of-an-inch across, with egg-shaped, broadly bilobed segments; tube somewhat inflated, constricted at the mouth where there is a ten-lobed ring.

This species is found in the Khasia Hills, in north-eastern India.

Culture: As for P. imperialis.

KIALENSIS (Franch.). Kia P.
(Farinosae.).

A dwarf species, with a tuft or rosette of leaves with egg-shaped or oblong-egg-shaped, blunt blades tapering to a short stalk, in all from three-quarters- to one-and-a-quarter inch long; upper surface more or less smooth, underside coated with yellow meal. Flower stem smooth, one inch to two inches tall, bearing an umbel of two to six blossoms on stalks a quarter- to three-quarters-of-an-inch long. Corolla about three-quarters-of-an-inch across, widely cup-shaped; lobes broadly egg-shaped, bifid; tube about half-an-inch long. The colour of the blossoms of this species has not been recorded.

Grows on the mountains of Kia-Kdzan, near Tatsienlu, in Szechuan, western China.

Culture: Good friable loam and grit, in a damp, open spot, should suit it.

KINGII (Watt.). King's P.
(Amethystina.)

A smooth, non-mealy, tufted perennial species with numerous, somewhat thick, elliptic-lance-shaped, pointed leaves two to three inches long, broad and sheathing at the base; margins quite entire or furnished with obscure, blunt, rounded teeth. Flower stem six to ten inches tall, slender, bearing an umbel of four to six reddish-purple or claret-coloured blossoms half-an-inch to three-quarters-of-an-inch across. Corolla broadly funnel-shaped, divided into five oval, retuse, scarcely notched lobes; tube cylindrical below, dilated upwards, longer than the calyx, smooth inside, downy without.

Grows in damp spots near Na-tong, in the Chumbi Valley, Sikkim Himalayas, at about 15,000 feet above sea-level.

Culture; Grow it in good loam and grit, in a well-drained, open spot, with plenty of underground moisture when the plant is in growth, and a pane of glass overhead in winter.

KISOANA (Mig.) Kiso P.
(Cortusoides-Geranioides.)

A tufted, perennial species with the whole of its foliage and stems more or less clothed with silky down. Leaves rounded, heart-shaped, about two-and-a-half inches long and the same across, borne on hairy stalks; margins furnished with rounded teeth or lobes. Flower stem four to six inches tall, bearing from two to five deep rose-coloured blossoms on stalks about three-quarters-of-an-inch long. Corolla about three-quarters-of-an-inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical below, dilated upwards, twice as long as the calyx. Illustrated in *Notes from the Royal Botanic Garden, Edinburgh*, 1913.

Grows in cool, shady places in the alpine regions of Kiso, south-western Japan.

Culture: As for P. cortusoides.

KITAIBELIANA (Schott.). Kitaibel's P.
(Auricula-Rhopsidium.)

This dwarf, perennial species is somewhat rare in cultivation. It has a tuft or rosette of elliptic or oblong lance-shaped, pointed or blunt leaves narrowing gradually to a winged stalk, in all one inch to three inches long; margins entire, furnished with recurved teeth towards the tip; both surfaces rather glaucous and dotted with viscid, glandular pits. Flower stem two to three inches tall, glandular, bearing one or two rosy-mauve or lilac, white-throated blossoms, which rarely rise above the foliage. Corolla flat, three-quarters-of-an-inch to one inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical, about three-eighths-of-an-inch long.

Grows in clefts in rocks and stony places in moist, somewhat shady spots, in the Alps of Servia, Croatia, Bosnia and Hezegovina.

Culture: Grow it in good fibrous, calcareous loam in a damp spot in half-shade, or plant in a cleft in a limestone rock packed with the above compost.

KIUCHIANGENSIS (Balf. f.). Kiuchiang P. (Nivales).

A handsome microform or sub-species of P. calliantha, with a tuft of oval or oblong leaves, one-and-a-half inch to two-and-a-half inches long, blunt or rounded at the tip, gradually tapering to a scarcely distinct, broadly winged stalk; margins furnished with regular, rounded teeth; underside coated with meal. Flower stem three to four inches tall, bearing an umbel of about half-a-dozen pale purplish-blue blossoms on stalks about a quarter-of-an-inch long. Corolla about one inch long, with broadly heart-shaped lobes; tube much longer than the calyx. Flowers in June and July. Illustrated in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. In cultivation in 1913.

Grows in damp, alpine pastures near Tsarong, on the Salween-Kiuchiang divide, in south-eastern Tibet.

Culture: As for P. calliantha.

KLAVERIANA (Forrest). Klaver's P. (Petiolaris-Davidii).

A beautiful perennial species with a thick, woody rootstock clothed with oblong, deciduous scales about half-an-inch long. The oblong or oblong-egg-shaped, somewhat membranous leaves have rounded or blunt tips and are nearly stalkless, or taper at the base into a wedge-shaped stalk, in all from six to seven inches long; margins furnished with regular, rounded teeth; upper surface brownish-green and covered with minute, meal producing, glandular hairs, underside paler. Flower stem six to nine inches tall, downy, bearing from two to three blue flowers on somewhat stout, downy stalks about half-an-inch long. Corolla about one inch across, smooth, with egg-shaped, entire lobes; tube cylindrical below, slightly dilated upwards, white at the base, half-an-inch long. Flowers in March and April.

Grows in damp, shady places, such as the margins of thickets, shady banks of streams and moist, rocky places in ravines, in north-eastern Upper Burma and south-eastern Yunnan, at 8,000 to 11,000 feet above sea-level.

Culture: Good friable loam and Oak or Beech leaf-soil, in a cool, damp, shady spot, with protection from damp in winter, should suit it. *A. W. Darnell.*

(*To be continued*).

PLANT PESTS IN EAST SUSSEX DURING 1928.

With us, the year 1928 does not stand out conspicuously as a bad pest year; with but few exceptions, extensive damage has been rare. The principal exceptions were aphides on fruit trees and the Currant capsid, Lygus pabulinus, doing damage to several kinds of small fruits. Observations on some of the pests noted are appended.

Coleoptera.—Apple-blossom weevil (Anthonomus pomorum, L.), was seen in several places, but little damage was done. The clay-coloured weevil (Otiorrhynchus picipes, Fab.) was common, and damage to growing nursery stock by the adult weevils was considerable. This pest is always a serious one and control measures are extremely difficult. Grease bands fail to trap the creatures, and poison wash or bait fails to account for many. It appears that the only method of keeping these weevils under control is to put down traps and collect them by hand. Loose hay-bands placed near the feeding positions are the most successful traps used by the writer, but such methods are slow, and one would like to employ some quicker method. The black vine weevil (O. sulcatus, Fab.) caused a good deal of damage in the larval stage to the roots of pot plants; this pest is also difficult to control, and a method that is both economical and practical is urgently needed. Trapping the adults gives fair results, but this does not help when the grubs are actually at the roots of the plants. If we had an insecticide with which to soak infested soil, to kill the pest and leave the plants uninjured, it would be a step in the right direction. Raspberry beetle (Byturus tomentosus, Fab.) was present in most gardens, but the damage was, perhaps, less than normal. Turnip flea beetles (Phyllotreta nemorum, L.) and other species were not a serious pest in the spring, but seemed to increase in numbers later in the year. This increase was probably due to the long, dry spell which was experienced in this district. Pea and Bean weevil (Sitones lineatus, L.) gave much trouble to market gardeners around the seaside towns. The pest appeared early; the spring was cold and the growth of Peas and Beans was slow, hence the weevil was able to do its maximum amount of injury. Control measures with this pest are very unsatisfactory, and it appears that at present we must rely upon cultivation and its effect upon the host plant to enable us to fight this pest. Nearly one hundred years ago, horticultural writers advocated the dusting of Peas and Beans with soot and lime as a remedy against weevil, and the advice is repeated parrot-like when Sitones is under discussion, even down to 1929, but if those who so write actually made a few observations for themselves instead of relying upon others, the remedy would not be advertised so freely. The soot and lime are not applied to kill the creatures, but to render the food plant unpalatable. The writer has coated Pea and Bean foliage with soot, lime and fine, dry garden soil, and fed the treated foliage to Sitones in large glass cylinders, but has not succeeded in starving the creatures; they eat treated foliage if nothing else is available. Much better results in the garden may be obtained by keeping the soil with a fine tilth, so that there are no lumps to shelter the weevils when not feeding, and by keeping the host plants growing fast. Sitones, of course, does not confine its attacks to Peas and Beans; almost every Clover plant in the country is attacked more or less, and this fact alone renders control measures difficult.

Hemiptera.—Aphis attacks on all cultivated fruits were above the average, except on trees winter-sprayed with good tar distillates, and one wonders how long it will be before gardeners in general will realise that tar distillate washes form the most effective means of controlling aphides, and that crippled foliage on any fruit tree only reflects bad management. Tar distillates are expensive, but, if applied well, they do their job. The Apple capsid (Plesiocoris rugicollis, Fall.) was not seen by the writer in any part of the county, but its ally, the Currant capsid (Lygus pabulinus, L.), was only too apparent. Black, Red and White Currants, together with Gooseberries, were attacked in most gardens; the effect of this attack on the crop of 1929 will require some attention. The capsid attacks the foliage of the selected host and because the fruits are not damaged, growers take little or no notice of the pest. To allow the Currant capsid to go on increasing at its present rate would seem to be dangerous, because it cripples so much of the leaf-surface and deforms the young growths to such an extent that future crops are bound to be affected, although it may take more than a year to do so. The control of the Currant capsid is difficult because it feeds on such a wide range of host plants. Nicotine applied in spring seems to be the generally accepted control, but the pest drops to the ground so soon as the spray fluid is applied to the bush, and it is necessary to spray the ground as well as the tree to effect any measure of control; this makes the cost of spraying rather high. Professor Theobald has obtained fair control over the Apple capsid, under west Sussex conditions, by using tar distillates in winter, but reports that no control was obtained over the Currant capsid by this means. Carrot aphis (A. carrotae, Koch.) was common in all districts, but no outstanding damage was noticed. The grey Cabbage aphis (A. brassicae, L.) was present throughout the season, and some damage was noticed, especially on Savoys.

Lepidoptera.—The various winter moths did not cause any serious damage, and tortrix larvae were not abundant on cultivated fruits. Raspberry stem bud moth (Lampronia rubiella, Bjerk.) was noticed in a few gardens when in the larval stage, but little damage was done. The larvae of the gold-tail moth (Porthesia similis), was very common on Hawthorn hedges, but was not seen on cultivated fruits. Many larvae were collected, and most of them were found to be attacked by a Braconid, which is probably their natural control. Codling moth (Cydia pomonella, L.), was, as usual, very local, and in the main little damage was noticed. Cabbages and Brassicas generally suffered much damage from Cabbage white butterflies and Cabbage moth, and some damage was noticed by the garden pebble moth (Pionea forficalis, L.). The pebble moth larvae are very common and a lot of the damage done by this pest is normally put down to the Cabbage white butterflies. Cutworms (Agrotis spp.) have been present in large numbers, and much damage was done to market garden crops; the scattering of bran, poisoned with Paris green, was employed with some success, but not until much of the damage had already been done. The diamond-backed moth (Plutella maculipennis, Curt.) did extensive damage in all districts.

Diptera.—Carrot fly (Psila rosae, Fab.) was common in all the smaller gardens, but the damage was not serious where Carrots were grown on a larger scale. Onion fly (Hylemyia antiqua, Meig.) and Cabbage root fly (Chortophila Brassicae, Bouche.) were present in all districts, but the damage was less than average, which was strange considering the dry period experienced. Celery fly (Acidia heraclei, L.) caused much damage, especially the last brood. The incidence of Diptera attack seems to require a lot of explanation. It is easy to say that flies are not so prevalent during a wet year compared with a dry year. The writer's experience in Yorkshire in 1927 was that few fly pests could be recorded because of the wet season, but last year in the south, after a very dry season, it was the same story. Perhaps it is just as well not to enquire into the incidence, rather let us be pleased that the flies did not do much damage.

Hymenoptera.—Gooseberry sawfly (Nematus ribesii, Scop.) was common in most gardens; where insecticides were used early in the season, the pest was controlled easily, but where neglected, much defoliation resulted. Pear sawfly (Eriocampa limacina, Cameron) was seen in a few gardens but chiefly on wall Pears. Apple sawfly (Hoplocampa tesudinea, Klug.) was common everywhere and caused many Apples to drop; the damage was, perhaps, more apparent than real, because most of the Apple trees which set any fruits at all were overloaded with small fruits, so that some thinning was desirable, and the sawfly probably did good.

Nematoda.—The presence of the Potato race of Beet eelworm (Hetrodera Schachtii, Schmidt.) was discovered in one allotment garden. This pest is rarely found in gardens where a good rotation is practised, but is liable to be troublesome in places, such as an allotment, where good rotations are not so easy.

Collembola.—Springtails caused some damage to cultivated Mushrooms in one district; they were present in huge numbers. The writer was present in one yard early in the summer and a strong wind was blowing, the springtails being blown out of the straw covering the Mushroom beds and collected under the wall; in this position they could be taken up by the shovel-full! *G. C. Johnson.*

WHITE TIP DISEASE OF LEEKS.

A disease of Leeks, at present called white tip, was found in the Midlothian districts near Edinburgh, in the autumn of 1928. It was at first accepted as the downy mildew of Leeks, caused by Peronospora Schleideni, although the symptoms, described below, were not of the usual type. In England, Dr. Pethybridge has noted on several occasions the white tip symptoms, and other observers have noted similar appearances. In the present instance, a species of Phytophthora has been found to be responsible for the disease. It is not supposed that the disease is new, but that it has not been recognised as a disease separate from that caused by the downy mildew fungus. Neither is it supposed to be confined to the districts already examined, since, as already stated, a similar appearance has been seen in England. When attention has been drawn to the fact that this is not the Peronospora disease, it will probably be found to be fairly generally distributed.

The growers around Edinburgh have noted white tip for some time, but have treated it as for downy mildew. It appears to be of some considerable economic importance, as several fields have been examined where hardly a single plant has escaped infection. Some resisted the attack more or less successfully, but the majority succumbed badly. The yield and market value was thereby greatly reduced.

The symptoms are as follow:—The tips of the leaves die back for a distance of one to four inches, and this area then becomes white. Most tips so affected become limp, while others become stiff and crisp. Some leaves are attacked at the margins, some distance from the tip, and again the area becomes white. Leaves affected in the latter manner become twisted in consequence. Later, water-logged areas develop towards the middle or base of the leaf. In these areas the fungus can be found. (See Fig. 57). The plants attacked rot away if they are large and mature, but remain stunted if young. Fields attacked can be recognised some distance away, as the purplish-green colour of healthy crops is replaced by a much lighter green colour.

The fungus responsible was discovered when leaves supposed to be attacked by Peronospora Schleideni were examined. It was noticed that the oospores taken to be those of the above fungus were fertilised in an amphigynous manner. So far as is known, Peronospora has only the paragynous method of fertilisation, and this fact immediately suggested that the fungus was a Phytophthora. Further examination showed a few paragynous antheridia and sporangia. The measurements of the fungus are as follows:—Oogonia: a range of 27 to 39 microns; oospores: a mean of 27 and a range of 20 to 31 microns; sporangia: very variable, ranging 37-75×31-48 microns (a mean of 58 ×42 microns). This fungus is proving difficult to obtain in culture, but work of this nature is proceeding. Until the fungus is obtained in pure culture, the exact diagnosis and life-history cannot be known.

Dr. Ashby, of the Imperial Bureau of Mycology, one of the best authorities on the Phytophthoras, very kindly examined the fungus and definitely diagnosed it as a Phytophthora, for which very grateful thanks are recorded. *C. E. Foister, Department of Agriculture's Plant Pathological Laboratory, Royal Botanic Garden, Edinburgh.*

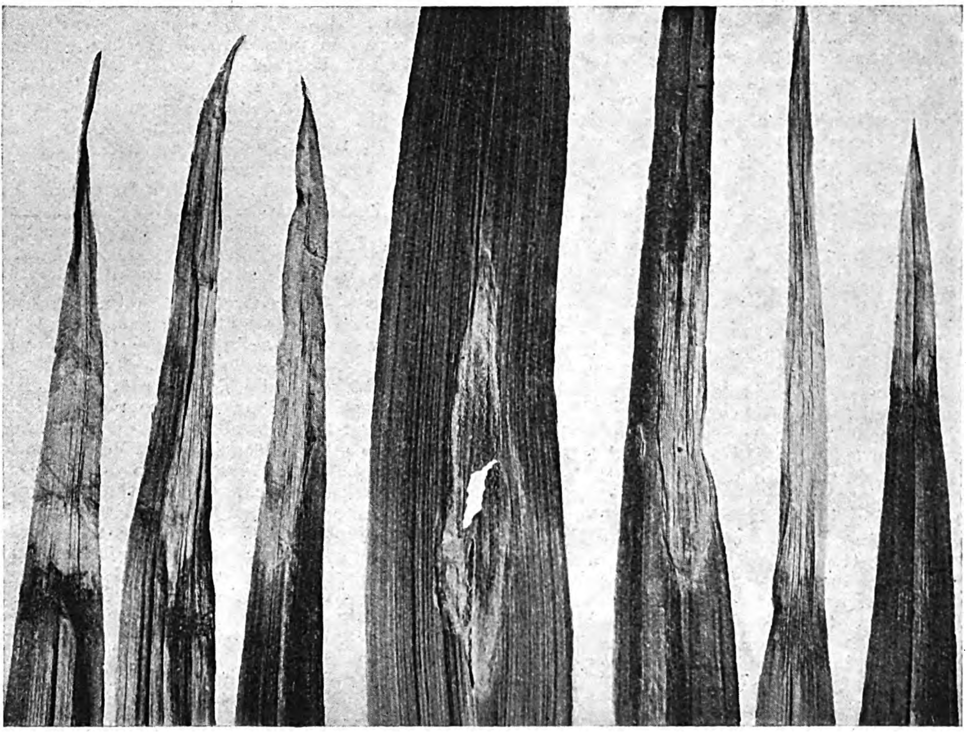

FIG. 57.—WHITE TIP DISEASE OF LEEKS.

THE BULB MITE.

For very many years the bulb mite, Rhyzoglyphus echinopus, has been known as an unwelcome creature to horticulturists throughout the greater part of the world. It was in this country originally known as the Eucharis mite, owing to its predeliction for that plant, and has since been recorded on a vast number of cultivated plants of widely diverse types.

It has been a matter of keen controversy as to whether this mite can attack healthy plants, or is merely a scavenger and follower of decay originally caused by some other organism.

The writer has studied the mite for a number of years, with a view to determining its real economic significance, more particularly with reference to its occurrence on Narcissi, but also on Tulip, Onion, Iris and other bulbs. As a result of this study, there is no doubt that, while, for a number of reasons, the mite is a most undesirable creature, it is nevertheless unable, by itself, to damage the above-named plants, unless they have become unhealthy, for some other reason. A brief survey of the life-history of the mite will be followed by a discussion as to methods of reducing its numbers.

The mite is a small sluggish animal, yellowish-white to pinkish in colour, and has a highly polished, translucent appearance. When fully grown, it is slightly smaller than a pin's head. The nymphs, or young mites, are very similar in appearance to the adults, only smaller, with the exception of the stage known as the hypopus. This latter is a highly specialised nymph of which more will be written later. It is small, shining and of a brownish colour, and is considerably harder than is the more usual form.

The mites occur in colonies of considerable size on suitable breeding grounds, such as beneath the outer scales, and around the basal plates, of Narcissus and Hyacinth bulbs. The female mites lay eggs freely and, in the positions previously mentioned, large colonies rapidly spring into being during the warmer months of the year. At all seasons, small numbers of the hypopal nymphs, referred to above, may be found in the colonies, but during the summer months enormous numbers of them occur. They are in reality the travelling stage of the mite. They do not feed, but wander about, in and around the colonies, until an insect, for example, a bulb fly, settles within reach. Then numbers of them seize hold of the insect and cling tightly to it. Owing to their small size, the insect hardly notices them and carries them around for some time. Eventually the hypopi drop off and, if alighting at a spot where suitable food is present, soon transform to normal mite nymphs and commence to feed and, in a very short space of time, a vigorous colony springs up.

As mentioned at the beginning of the article, it has long been debated as to whether or no the mites can damage healthy plant tissue. While there is no need to detail the experiments, which show clearly that they are unable to do so, a resumé of the results obtained is of interest. Under normal conditions of cultivation and storage, the mites cannot damage healthy Narcissus, Tulip or Onion bulbs. In fact, Narcissus bulbs kept out of the soil for thirteen months, and all the time covered with mites, were, at the end of that period, entirely undamaged.

As opposed to this, bulbs damaged by mechanical means, such as by being cut at the time of lifting, were frequently entirely destroyed by mites later. Similarly damaged bulbs, kept free from mites, eventually recovered. Bulbs attacked by bulb eelworm or bulb fly were destroyed more quickly when mites were also present on them than they were by the other pests working alone.

The results obtained with bulbs first subjected to the hot-water-treatment were of particular interest. Healthy bulbs so treated were in no case subsequently damaged by mites. Nor were bulbs which had previously been lightly infested with bulb eelworm. But, bulbs originally heavily attacked by eelworm or damaged by bulb fly larvae were often entirely destroyed by mites after treating. Similar bulbs kept free from mites eventually made a complete recovery.

A further point must be borne in mind. Narcissus and other bulbs are prone to a number of fungus diseases. Bulb mites are ubiquitous and wander freely from bulb to bulb while these are in store and are, in addition, carried among the bulbs during the growing season by bulb flies. The mites have numerous, long hairs on their bodies, and are thus able to carry spores of injurious fungi from one bulb to another in the course of their wanderings.

It is clear from the above that, while the mites are unable themselves directly to destroy healthy bulbs, they are, nevertheless, indirectly responsible for considerable losses. The desirability of reducing their numbers is therefore plainly indicated.

Before proceeding to a discussion of the control measures which may with success be adopted against the mites, mention may be made of a natural enemy, which serves in some measure to check their activities.

This natural enemy is another mite, a species of the genus Hypoaspis. It is an active, quick-moving creature, which wanders about over the colonies of bulb mites, on which it is predatory. At frequent intervals it seizes a bulb mite, which it carries about while sucking out the contents of the body, and finally discards. Half-grown larvae and nymphs are the stages of the mite most frequently attacked, for the adults are rather large to carry, and the hypopal stage too hard to pierce. Large numbers of these predators are often found in the colonies of bulb mites, and as they are very voracious, they undoubtedly dispose of large numbers. They are therefore of considerable value as a check on their activities.

CONTROL MEASURES.

Careful attention to the following points will do much towards maintaining a check on the activities of the mites, with a consequent reduction in the amount of damage attributable to them :—

(1) LIFTING.—Bulbs should invariably be lifted with care. Badly cut bulbs provide suitable breeding-grounds for the mites, and will, in all probability, not recover from the attack. Such bulbs should be discarded and destroyed.

(2) DESTRUCTION OF ROTTED BULBS.—Every cut or rotted portion of bulb will harbour mites, if left in the ground ; "hot-water-treated" bulbs, if planted over such material, will be liable to mass infection by mites. This may result in extensive losses and, therefore, all damaged bulbs should be collected and destroyed.

(3) STORAGE.—Bulbs should be stored under hygienic conditions and looked over periodically. Fungus storage rots may easily be spread by wandering mites, so, all soft bulbs should be picked out and destroyed.

(4) HOT-WATER TREATMENT OF BULBS.—The hot-water treatment, for the control of bulb eelworm and bulb fly larvae is well-known, and descriptions of the process are easily obtainable. The treatment also kills mites. Care must be taken that the bulbs are not subjected to re-infection by mites until they have had good time in which to recover from their previous injuries.

(5) EARLY TREATMENT OF EELWORM INFESTED BULBS.—The early diagnosis and treatment of eelworm-infested bulbs is essential in order to avoid serious subsequent losses from mite attack.

(6) FUMIGATION.—It is possible successfully to fumigate small quantities of bulbs in order to free them from mites. Paradichlorbenzene is the substance employed for this purpose, and full details as to the process will be given to any person wishing to use the method, which is cheap and effective. *W. E. H. Hodson, Seale-Hayne Agricultural College, Newton Abbot.*

HOME CORRESPONDENCE.

Cordon Pears.—I read with much interest *A. P.'s* article in your issue for January 26, p. 68. I have made a special study of Pears grown on the cordon system in the same garden for the past twenty years, and I am still at a loss to account for their strange behaviour with regard to flavour. I am convinced that weather conditions alone do not account for it. I have found the following sorts to be most consistent, and give them in order of ripening :—Beacon, Jargonelle, Louise Bonne of Jersey, Conference, Jersey Gratioli, Doyenné du Comice and Beurré d'Avalon, otherwise known as the Glastonbury Pear. I consider the last-named to be the best October Pear in cultivation ; it is better than Doyenné du Comice, but does not appear to be well known, except in the neighbourhood of Glastonbury. Few nurserymen catalogue Beurré d'Avalon, and I had some difficulty, some years ago, in procuring a dozen cordon trees of it. The fruits have a russet skin, dark red on the sunny side, and I advise all those who have not given this excellent Pear a trial to do so. Jersey Gratioli is a good September Pear, its fruits being of medium size and always well flavoured. The same remarks apply to Louise Bonne of Jersey, which has fruits of inferior appearance but very richly flavoured. I have been obliged to discard many of the leading varieties of Pears on account of their lack of flavour as grown here. I have, at times, come across excellent fruits of Clapp's Favourite, Gansel's Bergamot, Thompson's and Marie Louise, in Somerset and Derbyshire, but these sorts are quite useless here. Passe Colmar has quite a distinct flavour, suggestive of Almonds ; this flavour is quite pleasant at times, but is often so pronounced that the fruits are rendered uneatable. Like *A. P.*, I find the behaviour of Pears a most interesting subject ; their capriciousness gives a zest to their cultivation. *R. Carter, Miskin Manor.*

Number of Florets in an Exhibition Chrysanthemum.—I have often wondered how many florets—often called petals—constitute one of the modern full-sized exhibition Japanese Chrysanthemums. Therefore, to satisfy my curiosity, I set myself the task of dissecting a specimen of Louisa Pockett, measuring eleven inches in diameter. I laid the florets in heaps of one hundred, and when the operation was completed, I had before me the grand total of 975. The bloom was far past its best when I set myself the task of counting, therefore there were probably more florets when the flower was in perfect condition. I do not remember having seen in print, or hearing of, the totality of florets in a gigantic Chrysanthemum. *A. W. Warner, Gardener to the Countess of Hardwicke, Hamble Cliff, Netley.*

Partial Soil Sterilisation.—As one who, for the past five years, has been interested in soil sterilisation, using the baking method, my experience is that the baking process leaves much to be desired. My reasons for stating this are (1) cost of fuel ; (2) the amount of wasted heat outside the walls ; (3) length of time necessary to bring it to the required temperature ; and (4) the gases or fumes given off by the baking of the bottom six inches of soil permeate the whole, thereby destroying the beneficent bacteria or rendering them inactive for some time to come. This is most noticeable after potting Chrysanthemums in freshly sterilised soil. My experience, so far as our special soil is concerned is, that it is much better to wait a day or two, rather than to sow seeds in warm soil which is liable to cake after being pressed down lightly. Those who are fortunate in having plenty of shed room cannot do better than to start sterilising their soil two or three weeks prior to its use. No doubt the baking process is the most convenient in small gardens for the raising of seedlings, but where large quantities of soil have to be dealt with, some process similar to Mr. Falconer's (Vol. LXXXIV, p. 494) is the cheapest and simplest. *G. W. M., Dunham Massey.*

——As a gardener, I have been greatly interested by the letters in your pages on soil sterilisation, and now that the professionals have had their authoritative say in the matter, may I, an amateur, call attention to a few elementary points which there seems a danger of forgetting in all this discussion about ways and means ? The first thing to consider is the effect of sterilisation on the population of the soil, for it is upon numerous bacteria and possibly fungi that the soil's productivity depends. Completely annihilate these, and we render the compost unfit for any of the higher plants. To be beneficial, sterilisation must be only partial. Fortunately, however, our methods of sterilisation, while killing off weed-seeds and insects, indirectly benefit the soil-flora by killing protozoa as well. These organisms, which feed upon bacteria, are more susceptible than their prey, and cannot recover so quickly from such a severe check as that administered by volatile chemicals, baking or steaming. As protozoa increase, bacteria decrease—and the converse holds. As a result of partial sterilisation, the bacteria eventually become more numerous than they previously were, "fix" more nitrogen, and in other ways increase the soil's fertility. Both they and their enemies suffer greatly from sterilisation, of course ; the beneficial effect arises from the greater resistance and fecundity of the bacteria. This being so, the most useful method is that which affects least adversely the physical proporties of the soil, and which at the same time is most convenient and cheap in practice. Gardening only in a small way, I have never tried disinfectants ; as for the other two ways—steaming and baking—I find the latter much easier and quite as satisfactory as the former, and thus agree with Mr. Shewell-Cooper, whose leaflet, however, I have not yet perused. *W. T. S., Cambridge.*

Gardening Careers.—Your correspondent, *B. C.*, on p. 51, asks an important question concerning young men's prospects in the gardening profession. Having served for over fifty years in private and public gardens, I venture a suggestion which may be useful to him and other young men who may be contemplating a gardening career. Owing to the post war conditions, there is undoubtedly a depression in many private gardens at the present time. Notwithstanding this depression, there are still good prospects for enterprising young men in another sphere of gardening, namely, public service, where there is an increasing demand for gardeners as park officials, with a higher rate of remuneration than is usually given in private gardens. Hence, there is, in this field, a good opportunity for ambitious young men. Of course, they could not expect to obtain good positions without qualifying for them. *W. B. G.*

Pyracantha Rogersiana.—One has to think occasionally to remember the spelling of this name (see Vol. LXXXIV, p. 510, and p. 67). The introduction of new trees, shrubs and other plants proceeds at a greater pace than the books which record them in this country. I have now an American book which records the above shrub under the name of Pyracantha crenulata var. Rogersiana. A few weeks ago I had a scrap sent me to name, and had to rely upon memory, and called it Pyracantha Rogersiana var. flava, being the yellow-berried one, for which I have a great liking because of its distinctness from the general run of the species and varieties of Pyracantha, except some forms of P. angustifolia, which have pale fruits that are practically yellow. The intimation by Mr. Charles Coltman-Rogers that it makes "the best of garden hedges" should be welcome news to many, as it should succeed better than Lonicera nitida in town gardens, where I learn it sometimes loses its leaves ; and come in line with Berberis Darwinii. I have seen all sorts of plants used for the making of hedges, from Ligustrum vulgare (Common Privet) to Populus canescens, which grows very thinly. *F.*

Salix lanata.—On p. 60, *J.* states he has not been able to distinguish between Salix lanata and the variety Stewartii. In April, 1926, I had flowering specimens sent me from the gardens of the Royal Horticultural Society, Wisley, asking for a distinction. The specimens were labelled S. lanata var. Stuartii, and it would be well if the spelling were authenticated, as I have not yet seen it in any book. The specimens had the usual densely silky catkins, but the hairs were at first white, changing to grey as the catkins become more nearly full size. The year-old twigs were greenish, now they are dull dark brown. My specimens, collected in Mid Perth in 1906 and 1907, had pale canary-yellow hairs on the catkins, and that colour has been largely retained after twenty-one years. The twigs were brownish-yellow and more or less polished, the two-year-old twigs particularly so. The leaves are orbicular and rounded or subcordate at the base. The variety Stuartii has smaller, broadly oval leaves, narrowed to the base. The actual shape of the leaves, I think depends a good deal on the age or vigour of the bush, as I have obovate leaves from a small bush in the same colony. The plants at Wisley are too young to judge about the size the leaves may attain. Meantime, the leaves and catkins look distinct. *J. Fraser.*

Embothrium coccineum in Sussex.—This shrub, hardy in the south of England, is often known as the Fire Tree, which name well describes it, for when in flower it is a gorgeous mass of red, due to its numerous tubular blossoms.

E. coccineum has, I believe, a future before it, the only drawback being that it cannot be grown in the open garden in many parts of this country, as these are too cold for this Chilian shrub's happiness. The specimen with which I am acquainted, in a Sussex garden, is growing in a position which is protected from all winds, but at the same time, a moderate amount of sunshine can reach it. The shrub has flourished and attained a height of twenty-five feet, and promises to become a very striking and characteristic specimen. *W. Moseley.*

Cotoneaster Simonsii as a Hedge Plant.—A writer in the *Quarterly Journal of Forestry* for October, 1928, comments on the use of Cotoneaster Simonsii as a hedge plant in the neighbourhood of Inverness and other parts of Scotland. In such places as, for example, in the nursery of Messrs. Benjamin Reid and Co., of Aberdeen, it makes a hedge four to five feet high and fifteen to eighteen inches through, well furnished down to the ground. An evergreen—sturdy, clipping well and easy of propagation—this Cotoneaster deserves to have its name added to the none-too-long list of useful hedge plants. *K.*

VEGETABLE GARDEN.

PARSNIPS.

The Parsnip (Pastinaca sativa) cannot be stated to rank among our most popular vegetables, and its peculiar flavour does not appeal to every palate, nevertheless, it is a very useful winter vegetable which is in season throughout the winter months, and, if careful attention is paid to the cooking of the roots, they make a palatable and nourishing dish when other vegetables are less plentiful.

The Parsnip is one of the easiest vegetables to grow, and few roots give such a high return for the care bestowed upon them, for under favourable conditions the yield is enormous. It is not fastidious as regards soil, but a sandy loam, which enables the root to penetrate a considerable depth in the early stages of growth, is productive of the best results. While the use of fresh manure is not advisable in the preparation of the Parsnip bed, a moderately rich soil is essential for the production of good roots, for those which become stunted under starved conditions are lacking in both texture and flavour. A good plan is to grow them on ground heavily manured for a previous crop, such as autumn Cauliflowers; if the ground is deeply dug after the gathering of this crop, and left in a rough state during the winter, it will be in excellent condition for Parsnips without further additions of manure.

While the time of sowing must be governed largely by the state of the land, early sowing of the Parsnip crop is to be recommended, and so soon as the ground is in good friable condition, the seeds should be sown. They are somewhat slow in germination, and if they can be sown early enough for the young plants to become established before the drying winds of March rob the soil surface of moisture, it is a great advantage to the crop; on the other hand, it is better to wait than to sow them on wet ground, as the soil becomes caked and never works so freely afterwards. The seeds should be sown thinly in drills fifteen inches apart, covering them to a depth of about one inch. The hoe should be plied so soon as the seedlings appear, and, if the plants are thinned to ten or twelve inches apart, little further attention will be required beyond frequent hoeings throughout the season.

The Parsnip crop is in season from November until April and is much better left in the ground than lifted and stored. When spells of frost are expected, a few rows may be covered or some may be lifted to carry on supplies, but Parsnips retain their flavour much better in the ground than if lifted and stored. There are several excellent varieties of the Hollow-crown type, of good form and superior flavour, which have all the qualities desirable in a table vegetable. *W. A.*

SOCIETIES.

SALISBURY GARDENERS'.

The Lecture Room at the White Hart Hotel, Salisbury, was filled to overflowing on Wednesday, January 23, by members and friends of the Salisbury Gardeners' Society, on the occasion of a lantern lecture, "The Making of the Plant World of To-day," by Miss Barbara Gullick, B.Sc., daughter of the popular Secretary of the Society.

The Chairman, Mr. S. W. Tucker, in introducing the lecturer, said how very pleased they were to welcome her. They still had in mind her lecture on wild flowers, from which evolved the Wild Flower Scheme taken up by the City Corporation, which occasioned a considerable amount of interest throughout the district. The lecture that evening was in response to the unanimous invitation of the members of the Society.

Starting from the red-hot earth, the lecturer outlined the progress made by plants, from a time previous to the formation of coal, through the age of the giant reptiles, to the earliest flower which was already evolved before the chalk was laid down. (Attention was called to the present-day survivors of types once dominant over the whole earth, as well as to certain links in the chain of progress, which have now become extinct). After an outline of the opinions held through the ages on the mechanism of evolution, the lecturer showed slides suggesting the more recently advanced theories accounting for the rise of new forms in plants, leading to the conclusion that a great future for gardening lies in close observation, and intelligent plant-breeding.

Animated discussion followed, particularly on the remarkable acceleration of the rise of new forms created by the help of man, in comparison with nature unassisted, which has eternity in which to experiment. Mr. J. Pinder, in proposing a vote of thanks to the lecturer, mentioned how very much the Society was indebted to her for such an intellectual discourse. He was of the opinion that if the younger generation of gardeners would interest themselves more in the scientific side of horticulture, it would in due time benefit mankind in general. Mrs. Towner, seconded the proposal, and it was enthusiastically carried. The lecturer suitably responded.

On the proposal of Mr. W. F. Gullick, a hearty vote of thanks was accorded Mr. C. Craske for the loan of lantern, and manipulating the same. Some fine examples of Cypripedium Sanderianum were exhibited by Mr. W. Asher, and giant Parsnips by Mr. A. J. Hooper.

BRITISH DELPHINIUM.

This Society, which was only formed four months ago, held its first General Meeting at the Royal Horticultural Society's Hall, Vincent Square, on January 29.

There was a moderate attendance of members, presided over by Mr. C. F. Langdon, who opened the proceedings with a short speech, in which he spoke of the aims of the Society and of the interest already displayed by its members. He stated that the Delphinium had now risen to such a position as a border and a florist's flower that he considered it essential that there be a Society to further its interests. He appealed to amateurs especially to exhibit at the annual show, and expressed the hope that the interest of the amateur in the Delphinium would always be pre-eminent. Finally, he spoke of the splendid foundation that had been laid for the Society, through the activities of its officers.

The proposal that the Marchioness of Londonderry be elected President of the Society was made by Mr. Brandon, who, in making the proposal, spoke enthusiastically of the future of the Society, and appealed to all the present members to use every endeavour to enrol others, while he also emphasised the value and power of advertisement in promoting the growth of the Society. His motion was seconded by Mr. G. A. Phillips, and passed unanimously by the meeting.

The Hon. Secretary, Mr. S. Halford Roberts, then described the work done in connection with the Society since its inception, and also outlined the channels in which the Committee considered the future activities of the Society should be directed. He stated that there were now one-hundred-and-three members, including some in Canada, the United States of America, and Holland. The Society had become affiliated to the Royal Horticultural Society, and by so doing had been enabled to secure the latter's hall, free of charge, for the annual Delphinium Show, to be held on July 5. Mr. Roberts stated that several offers of medals and cups had already been received, and that the schedule for the show would be ready in a few weeks, when copies would be sent to each member. He stated that the Committee proposed to include in the schedule several articles dealing with the culture of the Delphinium, and also that a register of recognised named varieties of Delphiniums was also in course of preparation.

The Hon. Treasurer, Mr. G. D. Gold, being absent, a statement of the financial position of the Society, which appeared to be very satisfactory considering the short time it has been in existence, was placed before the meeting by the Hon. Secretary. The meeting then proceeded with the formal re-election of officers: Mr. G. D. Gold was re-elected Hon. Treasurer; Mr. S. Halford Roberts, Hon. Secretary; and Mr. A. J. Moir, Hon. Assistant Secretary. The Committee, Messrs. G. F. Langdon, G. W. Leak, C. A. Phillips, T. Carlisle, T. Bones, R. C. Pulling, A. J. Macself, Thomas Want, G. F. Barney, C. Reynolds, Mrs. Jenkins and Mrs. Roberts, was re-elected *en bloc*, its number being added to by the election of Mr. J. Kelway.

Mr. W. Hitch and Mr. G. S. Sandercombe were elected Hon. Auditors of the Society, and the meeting was brought to a close with a hearty vote of thanks to the Chairman.

BRITISH CARNATION.

The Annual Meeting of this Society was held in the Lecture Room of the Royal Horticultural Society's old hall, Vincent Square, on January 29, the number of members present being rather larger than usual. Mr. C. Engelmann, the retiring President, presided.

The notice convening the meeting was read, followed by the minutes of the last Annual Meeting, which were passed by the meeting. The Annual Report of the Council, copies of which were given out to the members present, was then discussed and severely criticised. The Chairman proposed that the Report be passed by the meeting, whereupon Mr. J. S Brunton objected, stating that the report, from a grammatical point of view, was a disgrace to the Society and not fit for publication. This lead to a very heated argument as the report had been drafted by a sub-committee, and had been passed by the Council after careful consideration. Mr. J. S. Brunton gave several instances to back up his statement, and formally moved an amendment, that the report be referred back to the Council to be re-edited. The amendment was seconded and put to the meeting, but was defeated, after which the vote was taken for the adoption of the report, which was carried. The report was a very lengthy one, dealing chiefly with the Society's annual show; *The Year Book*, which was issued for the first time last year; the visit of members of the Society to the nursery of Messrs. C. Engelmann, Ltd., and obituary notices.

Mr. L. J. Cook then read the statement of accounts, which showed that receipts for the year amounted to £487 12s. 1d., and expenditure, £377 3s. 5d., the balance in hand being £110 8s. 8d. The Treasurer pointed out that the expenditure was considerably higher than for the preceding year, and suggested that the curtailment of expenses during the coming year was advisable. The statement of accounts was then passed by the meeting, which next proceeded with the election of a President to succeed Mr. C. Engelmann. Mr. M. C. Allwood proposed that Lady Hudson be elected President of the Society, and stated that he had received a notification from her to the effect that she would be pleased to act as such if elected; the motion was seconded by Mr. T. Stevenson, and passed unanimously by the meeting. Mr. A. Metcalfe was proposed as Chairman of the Council, but the Secretary read a telegram from him stating that he did not wish to stand, whereupon Mr. G. T. Miller, seconded by Mr. M. C. Allwood, proposed that Mr. E. T. Willis be elected, a proposal which received the full approval of the members present and resulted in Mr. Willis being elected by a unanimous vote. Mr. F. Jordan was elected Vice-Chairman of the Council.

Mr. P. F. Bunyard was re-elected Hon. Secretary; Mr. L. J. Cook, Hon. Treasurer, a post he has held for twenty-one years; and Mr. E. F. Hawes, Show Superintendent. Mr. T. Pincher, with Messrs. W. J. Calder and Sons, were elected Hon. Auditors.

The next business before the meeting was the re-election of the retiring members of the Council, with a few exceptions, and the filling of the vacancies that had occurred. The retiring members re-elected were Messrs. F. W. Alesworth, A. Bedford, R. Campbell, M. Harris, and P. M. Patterson; while the new members elected were Messrs. M. C. Allwood, R. H. Hall, C. Engelmann, J. D. Simpson, E. S. Mason, M. Stather and J. W. Scott.

The question of trophies and cups was referred to the Council, after which Mr. Brunton expressed the thanks of the Society to Mr. C. Engelmann, for his services as President during the past year; to Mr. M. C. Allwood, who held the post of Chairman of Council, and to the other officers who had served the Society during the past year.

With a vote of thanks to the Chairman, and after another futile appeal by Mr. Brunton that the annual report be revised, the meeting was declared closed.

BRITISH FLORISTS' FEDERATION.

The annual meeting of the members of this Federation was held during the afternoon of Thursday, January 31, at the Connaught Rooms, Great Queen Street, London, W.C. Mr. J. Artindale presided over a rather small attendance. After the initial formalities had been disposed of, the Secretary, Mr. C. H. Curtis, read the Report of the Committee and Accounts for 1928. The former set forth the work done in connection with efforts to bring the flower-growing industry under the Safeguarding of Industries Act; the clearing of street traders from the vicinity of Covent Garden Flower Market; the handling of flowers and return of empties by railway companies; and the organisation of the British section at the great Ghent Show, which was attended with great success, thanks largely to the efforts of Mr. Jolis and Mr. George Monro, and the generous financial assistance from the Royal Horticultural Society and many friends.

The Accounts showed a balance of £110 17s. 2d. in favour of the Federation. The Ghent Show expenses came to £357 18s. 10d., while donations towards the cost amounted to £274 19s. 8d., leaving £82 19s. 2d. to be found by the Federation.

In moving the adoption of the Report, Mr. J. Artindale said that the membership of the Federation was far too small considering its importance. It was really the only Association which was solely connected with the flower trade, and each member should endeavour to induce other people to join. One suggestion he would make was that they should alter the date of the meetings, and hold them, say, once a month, or once in two months at Westminster, so as to give provincial members a better chance to attend. The Federation's part in the Ghent exhibition was really great, and everybody pulled their weight. He then referred to the loss sustained by the deaths of Mr. H. T. Mason and Mr. W. H. Page, who were very keen on the welfare of the Federation, and never missed a meeting. He hoped their positions would be taken by some younger members of their respective firms.

Mr. W. E. Wallace, in seconding, referred to the very good report, but regretted that the Federation was not getting the recruits it deserved. He referred to the loss of "two of nature's gentlemen," and the meeting stood in silence as a token of respect.

In moving a vote of thanks to the officers and Committee, Mr. Mills said that if the Committee could be given more work to do, they would be only too pleased to do it.

Mr. G. Monro, when moving the election of Mr. C. Engelmann as President, said that while the Federation did not increase in numbers, he thought that the standing and the weight of its members was increasing each year. The railway authorities and the French Transitaires, and the Covent Garden authorities, looked upon it as a much more united body than they did a few years ago; Mr. C. Engelmann was interested in the commercial side of horticulture, and his varied experience fitted him to act as President. Mr. D. Ingamells, in seconding, referred to Mr. Engelmann as a worthy successor to those who had preceded him.

Mr. Engelmann said he was very reluctant to accept the position, and to follow the series of excellent Presidents. One reason he did accept was because he appreciated the honour, and found it very difficult to say no. "Our B.F.F. has a big name, and we should represent the whole of the florist industry—and when I look at our membership list and balance sheet I am disappointed. I do hope we shall get more members, because in other countries we are looked upon as a 'very big thing.'"

Messrs. George Cobley and Co., Southampton Street, were heartily thanked for services rendered and re-appointed Hon. Auditors.

Mr. Ingamells then moved that the *Bulletin* be restarted. He said that it would be a very important link between the Committee and the provincial members. In seconding this, Mr. Monro said that the Federation had few other means of advertising itself. The motion was adopted, and the Secretary stated that he was more than delighted that the meeting had passed this resolution. When the Committee decided to drop the *Bulletin* on account of the expense he felt that they were losing touch with members.

Mr. White then moved "That the Committee take an early opportunity of discussing how the membership of the Federation can be improved." In seconding this resolution, Mr. Artindale urged the holding of at least six meetings a year. Mr. Fincham said his mind went back to a meeting held in the Strand, and he wondered whether the Committee could not do something more in the winter to gather members of the Federation together, and discuss subjects of interest to the trade. He moved, "That as time allows, a subject of interest to the Federation be brought up and discussed." This, like the previous motion, was carried.

Mr. J. W. Cross, Wisbech, and Messrs. J. H. Lalham and Co., Norwich, were elected members.

This concluded the general business, and tea was served prior to the address promised by Mr. H. Jolis.

A Buyer's View of the Marketing of Flowers and Plants.

Mr. Jolis stated that in Covent Garden Flower Market he always felt as though he were in Paddington Station, with a few flowers thrown in and about, and he was thoroughly ashamed to take his friends who were not in the trade. Members had the privilege of working in the most beautiful trade in the whole world, and yet could find no better way to dispose of the flowers! And if he, as a buyer, was ashamed, what must the grower feel like, who had spent months in bringing his flowers to perfection? It is exactly the same place as it was thirty years ago, in spite of the growth of the trade, but he was looking forward to the future, and believed that the future of the Federation was bound up with the future of Covent Garden. Indeed, he hoped the time would come when Covent Garden Market would belong to the trade, and be used by the trade for its best advantage. There was a time when it was possible for the trade to buy Covent Garden Market; that opportunity was allowed to slip. Much might be done to improve the market for the display of flowers; outside firms displayed their flowers and made things convenient for buyers. There was a lot of rubbish in the market, and that had the effect of making good quality blooms look third rate.

One of Mr. Jolis's grievances was the variation in prices; no one seemed to really know what the stuff was worth; it was one price early, and an hour or so later there might be a drop of 2s. In regard to cash buying, he considered business was done in a loose way; if some firms could give sale slips, why not others? The reception of the flowers at the market was bad, and should be improved.

He had been fortunate enough to visit some of the most wonderful cut-flower nurseries in this country, and had seen Carnations that were marvellous, but generally, the grower cut too late. A bloom cut when it is perfect is not perfect when bought, and still less perfect when it reaches the ultimate purchaser. It has, say, six hours in water and twelve hours in a box; it is then bought and taken away by the florist, and is probably on show another six hours before being sold. The grower looks at his perfect blooms, and forgets that directly they are perfect they begin to deteriorate.

Mr. Jolis offered many other criticisms regarding bunched flowers, length of stem, and packing paper; the lack of variety in flowering plants, and the apparent absence of the regulation of supplies of flowers.

In Mr. Jolis's opinion, one of the first things to be done was to hold the market for the benefit of the trade, and make the market a place for the display of the finest flowers the world produces.

In opening the discussion, Mr. Monro said that every one of the members ought to thank Mr. Jolis for the way in which he had laid before them some of the points which they knew were wrong; some of the points which were wrong which they did not know; and some points which, perhaps, they did not agree with; but without doubt, nothing but good could come out of a discussion of that kind between the different sections of the trade. Almost every single sentence expressed by Mr. Jolis made a point that they could appreciate, and in some cases alter. One or two points he wished to refer to. Variation in prices was a sore point with retailers. To a great extent that was absolutely unavoidable; they had a perishable article which had to be sold during the best period of its life, and the demand varied so much that it was quite impossible to avoid a variation of price and quality during the market hours. Sometimes prices fell, sometimes they rose, but he could assure Mr. Jolis that the variation was not so great now as it was in the past, and the salesmen did what they could to avoid an undue variation. He agreed with Mr. Jolis about the damage done to flowers if put on show; but this counsel was the counsel of perfection. Mr. Jolis's point of view was not necessarily that of all other buyers. In regard to bunching, the large bunches have evolved themselves according to the demand of the buyer. There was a time when Chrysanthemums were received in handle baskets, each containing about twenty-four bunches. And he could go back to the time when every single bloom came loose. Then came a request that growers should bunch everything, except specimen blooms, and the growers acted accordingly. As to paper, he agreed they often saw most awful colours, and the most fearful combinations of paper flower and colours. He thought the trouble started when the growers of Chrysanthemums were also growers of Tomatos, and they used the same kind of paper for flowers as they used for packing their Tomatos. They had to remember, however, that all types of packing were evolved at the request of, or in an endeavour to please the buyer, who had the last word.

Mr. A. W. White said that although he did not agree with all that had been said, some of it was very sensible. He was firmly convinced that if every bunch of forced Tulips was wrapped up nicely in a sheet of paper, the right way out, it would be of benefit to the trade, yet not only salesmen in London, but in the provinces also, think there is something wrong with flowers when so packed. Even when one was left open for show they thought it was a special sample. Growers knew very well that a bunch of Tulips thus wrapped would carry better to the other end, but they could not persuade the buyers that this was so. Mr. Jolis wanted a young flower with a long stem; that was not possible in many cases, but if a Daffodil were cut a day later it would have another inch of stem, and still be a good bloom. "We do want records," said Mr. White. If a man sells at various prices, how can he know what to pay us. All he can do is to pay us as much as he thinks we will be satisfied with! The retail buying that went on in Covent Garden was a nuisance, people who come round and buy eighteen-penny-worth of flowers should be prohibited by the market authorities. From his point of view, as a grower living one hundred miles away, he had often wondered at the little variation in the prices, not only in Covent Garden, but throughout all the markets in Britain. The value received for Daffodils and Tulips he was sending to eight markets would not vary more than five per cent.

Mr. Ingamells stated there was not a salesman in Covent Garden who did not keep a record of every sale he made. In regard to bunching, the smaller blooms were bunched in sixes or twelves because they travelled better. He was glad the meeting had decided to re-issue the *Bulletin*, and he hoped Mr. Jolis's paper would be printed therein, for the benefit of salesmen and growers.

Mr. Fincham spoke from the point of view of one who was both grower and salesman. Mr. Jolis denounced Covent Garden, but he (Mr. Fincham) had never yet seen good stuff remain unsold. As one who loved Covent Garden, he considered flowers wanted nothing to adorn them. He was all in favour of improvement, but who would foot the bill? The salesman cannot pay more rent, and the cost of improvements would be passed on to the grower, not to the consumer. In regard to bunching and packing, if he offered a special line and buyers asked him to save some boxes for the following day, he did not change his method, and if the buyer came back again he regarded the packing as satisfactory.

Mr. Jolis replied to points raised, and was accorded an enthusiastic vote of thanks.

A circular letter was then read from the Dutch Flower Export Company of Haarlem, touting for private orders. Mr. Jolis and Mr. Artindale said that a matter like that justified the existence of the Federation, and they thought it provided a very strong case for the Ministry of Agriculture in regard to some form of safeguarding. Mr. Engelmann considered that to ask for a tariff on imported flowers was like crying for the moon, but they should ask for the application of the Act for marking foreign produce.

In moving a vote of thanks to the President, Mr. White said they had had Mr. Englemann on the Committee and had proved him there, and now they had found him an excellent President.

Later in the evening, members and friends, including many ladies, dined together at the Connaught Rooms under the Presidency of Mr. C. Engelmann. The tables were beautifully decorated with Tulips, Daffodils, Carnations and Roses, and an excellent musical programme was provided. The principal speakers were the President, Sir James Slade, Mr. H. Jolis, Mr. Artindale, Mr. A. A. Fincham and Lt.-Col. F. R. Durham.

LEEDS PAXTON.

The above Society held its annual Dinner on January 26, at the Victoria Hotel, Leeds; there were several representatives of other West Riding branches, and of Leeds University present.

Mr. C. F. Pragnell, the Chairman, in proposing the toast of "The Society," said he wished to acknowledge the good work done by the Committee and Secretary, Mr. F. Goodhind. The Society had never been so well served as during the past year, and so long as it had efficient and active officers, it would always remain on a sound basis.

Mr. H. J. Hall proposed the toast of "Members from Kindred Societies." Mr. L. Lodge, responding, stated that he would like to see closer relations existing between the various Paxton Societies of the West Riding. Mr. W. J. Morley (Wakefield) said he thought the Leeds Society should make much more use of the Leeds University.

Obituary.

Gerald Garnett.—By the death of Mr. Gerald Garnett, North Lancashire agriculturists, horticulturists and cricketers have lost a friend and supporter. At the home of his family, Wyreside, Dolphinholme, which estate adjoins the Abbeystead Estate of the Earl of Sefton, where His Majesty the King has on several occasions enjoyed grouse shooting, the Garnetts have a fine estate, and the gardens are noted for their Rose gardens and herbaceous borders, which have been Mr. Gerald's special interest, while Ulverston, Southport, and Lancaster have borne witness to the excellence of the cultivation at Wyreside. Mr. Garnett, in addition to being a highly successful exhibitor at these shows, was always willing to stage a non-competitive exhibit at other shows. He was the youngest son of the late Mr. H. Garnett, was educated at Cheltenham, and was afterwards prominent in agricultural and cricket circles, on several occasions a team of cricketers from the family challenging established teams, in 1874 defeating the Western C.C. at Manchester, and in 1876 the Free Foresters at Sutton Coldfield. He had a long connection with the Lancaster C.C., and for several years headed the batting average. He was prominent in all farming circles, and was the first Chairman of the Lancashire and Westmorland Farmers' Association, occupying this position for twenty years, and was connected with the Royal Lancashire Agricultural Society's Show. For many years, however, his chief interest was in the gardens at Wyreside, where he was known as a keen Rosarian and a discriminating and successful grower of herbaceous plants.

René Jadoul.—We regret to announce the death of M. René Jadoul, a prominent figure in Belgian horticulture, at the age of sixty-one years. He was a nurseryman at Gembloux, and was general secretary of the Belgian Nurserymen's Syndicate; he had obtained the distinction of Chevalier de l'Ordre de la Couronne and several other decorations. He was born at Lille, and there obtained his horticultural education, but on the death of his father he settled in Belgium and founded at Gembloux his nurseries and seed-grounds. There he quickly became the centre of horticultural life; he specialised in Dahlias, but was a successful all-round nurseryman, and had a large clientèle. Unfortunately, the trials and difficulties of the war period undermined his health, and he was obliged during the last few years to curtail his multifarious activities. He died quite suddenly, having appeared, until twenty-four hours before, to be in fair health.

James Wilson.—Late of Messrs. Brown and Wilson, Market Place, Manchester, Mr. James Wilson died at his home, 4, Duncan Road, Langsight, in that city, on Friday, January 25, aged seventy-two. The son of a well-known East Lothian farmer, he served his apprenticeship to the seed trade with Messrs. Drummond Brothers, of Edinburgh, in the 'seventies of last century. Entering the service of Messrs. W. Drummond and Sons, he spent about three years in Stirling, and was subsequently in the employment of Messrs. Thomas Perkins and Sons, Northampton. In the early 'eighties, he came to Manchester as first counter-hand with Messrs. Dickson, Brown and Tait, in whose service he remained until 1888, when he, and the late Mr. John Brown, entered into partnership, and established the business which is still carried on at the same address. On the death of Mr. Brown, in 1902, he was joined by Mr. Manby Gibson, and the partners continued the trade of agricultural and horticultural seedsmen until July, 1927, when, owing to Mr. Wilson's declining health, the business was sold to its present proprietor, who stipulated that he should retain the old name. Mr. Wilson was one of the first to recognise the sterling qualities of the wild White Clover, which early came under his notice at the Cheshire County Agricultural College at Holmes Chapel, and whose merits he proved on his brother's farm in the Lothians. In those days it was more difficult to induce farmers to buy seeds of it at half-a-crown a pound than it was when the price soared to one guinea and upwards. Mr. Wilson was of a genial disposition and much respected by all with whom he came in contact. He leaves one son who, however, is not interested in the seed trade.

ANSWERS TO CORRESPONDENTS.

Creepers for Walls, etc.—*C. N.* (1) The most effective creeper for keeping a wall dry is the Irish Ivy, which is evergreen, has broad leaves, long stalks, and the blades hang down and thus shoot off the rain as it falls. There are other broad-leaved varieties, such as Hedera Helix Roegneriana and H. H. dentata, but they are not more effective in keeping off rain, while the latter is more open in habit. There is usually a difficulty in getting clinging climbers to adhere to a lime-washed surface, but boards or a trellis would overcome the difficulty. Ivy is suitable for both the walls mentioned. (2) The Oak logs will not interfere with the drainage of the rockery, but they have two faults. They are liable to decay after a number of years and let the soil down. That may be remedied by rebuilding the portions that sink. The rockery may want replanting in any case by that time. Wooden logs also harbour voles, otherwise named field mice, which eat off the bark of the shrubs. This will not matter so much, if no shrubs are planted on the rockery. It will be necessary to add at least six inches of a compost of loam, leaf-mould and sand over the clay for alpine plants.

Cumberland Natural Grasses.—*J. B.* It would be necessary to flower the grasses on any particular piece of turf to be certain as to what it contained, but the more common and most likely species are Festuca ovina and its varieties, F. duriuscula, Agrostis vulgaris, A. alba, Poa pratensis, P. nemoralis, P. trivialis, Anthoxanthum odoratum, Cynosurus cristatus, Phleum pratense, Alopecurus pratensis, Avena pratensis, and A. pubescens. More common at lower elevations than the above are Agrostis canina, Trisetum flavescens, Triodia decumbens, Koeleria cristata, Molinia caerulea and Lolium perenne. With the exception of the last-named, this second list is never sown for the purpose of making a lawn. Some of them might be present in Cumberland turf, and some of them might be avoided when the turf is being cut. The two species of Avena in the first list are likely to be only occasional. All of the above grow in Cumberland and many more besides.

Names of Plants.—*W. S. L.* Helipterum eximium, South Africa. — *G.* Petasites fragrans; Aucuba japonica var. dentata.

Plum Trees Failing to Fruit.—*R. J. C.* Your Plum trees ought not to fail to fruit unless the compost or cultural conditions are at fault in some way or other. Few hardy fruits present less difficulties in their culture; they succeed equally well exposed to any aspect unless the flowers are damaged by late spring frosts. The soil should be of the best to compensate for the absence of sunshine to warm the soil on north and east aspects. Good drainage must be provided and where no natural chalk or lime is present in the soil, some must be added before success can be attained. If you think your trees are in soil that is not well-drained or is lacking in lime, lift them, cut back any strong roots, arrange the roots near the surface where the soil is drier and warmer, and mulch and water during the summer months. Winter spraying should not be necessary every year, as, under healthy conditions, the Plum is less subject to disease than any other stone fruit, and aphides are easily dealt with during the growing season.

Plant Breeding Problems.

The high hopes with which the new science of Genetics was launched at Cambridge in 1909 must remain vividly impressed on the memory of all who, after the establishment of the Balfour Professorship, heard William Bateson deliver his introductory lecture. The key to the mysteries of evolution seemed to be in his grasp, and he spoke in the spirit of *claviger* of the broad river of progress that lay ahead. Where are we now? As Bateson regretfully admitted at Montreal in 1922, the origins of species are, perhaps, more obscure, or, at least, as controversial as they were before the coming of Mendel. The workings of heredity are, perhaps, less mysterious and more subject to control than they were; but the practitioners of the applied science of breeding have been disappointed. The laws of Mendel, precise as they are, are not proving to be ready tools; we still await the mass production of animals and plants dowered with desirable economic qualities. In the technical terms of the geneticist, *quantitative* characters are not so amenable to discipline as *qualitative*; the aesthetic perfection of a "Ruby" Primula is not paralleled by a super-sweet Sugar Beet, or a five-hundred-egg hen. The facile successes of the cereal breeders are not likely to be repeated. Some of the obstacles to progress may be gleaned from Mr. F. L. Engledow's review of plant breeding in a volume[*] recently published by the Royal Agricultural Society. Perhaps the greatest difficulty of all arises in this manner. In relation to methods of fertilisation all plants fall into one or other of two categories: Autogamous, or self-pollenating; exogamous or out-pollenating, and—here is the breeders' difficulty—some of the latter class are definitely self-sterile; they will not set seeds when selfed. The cereals and most of the Peas are normally self-pollenated, whereas the Brassicas and Beets are normally cross-pollenated; and of the latter the Cabbage is self-sterile. Plants which are normally selfed have, from the breeder's view point, this advantage: It is easy to establish a pure line, that is, a stock starting from a single plant and breeding true. Moreover, a pure line of such plants remains free from contamination—loss of purity—when grown in the open. But an out-pollenated plant does not breed true, being always open to foreign pollen. The breeder finds it difficult (or, if there is self-sterility, impossible) to start from a single plant and to protect a mass of plants from outside pollen. As Mr. Engledow shows, recent work on the Brassicas has brought this difficulty to the front, Cabbage, Brussels Sprouts and Borecole being absolutely self-sterile, and others, such as Kohl Rabi, very nearly so, although crossing freely *inter se*. But now a further and less amenable difficulty crops up. It seems to be a fact that, for some reason of which the scientific explanation is in doubt, heterozygous, that is, non-true-breeding plants, are naturally more vigorous than homozygous or true-breeding plants. The F_1 generation of a cross generally overtops its parents. Recent American work with Maize has proved that if the plant is continuously selfed, and so made "pure," it becomes, commercially, quite worthless as "corn." It is consequently a fair inference that in the case of plants of the Cabbage tribe their economic qualities of vigour, etc., are consequent on their condition of (for want of a better term the breeder calls) heterozygosity. If this, indeed, should prove to be the case, the difficulties of the scientific breeder are greatly aggravated. As Mr. Engledow trenchantly points out, there is no problem in genetics that more urgently awaits solution than the inheritance of such quantitative characters as vigour, and particularly the precise meaning of heterosis, the term which the American school invented for the phenomenon of hybrid vigour. Speculations have not been wanting. One of the first will be found in the early literature[†] and was the suggestion that heterosis is due to the meeting of dominants; this view is now in favour in the U.S.A. The difficulty in relation to this explanation of the matter is that the vigour, so far, has not turned up again in subsequent generations as theory would require. There is much of scientific interest in this new work on the Brassicas, of which Mr. Pease, of Cambridge, is the chief exponent in this country. The chromosome numbers of the eight species of the genus differ one from another with one curious exception. The same figure—9—is found in the Cabbage and Radish groups, with the expected result that, with this exception, the species are inter-sterile. The bulb of Kohl Rabi is conditioned by three clear Mendelian factors. Of some spectacular—if not of economic—interest was a descendant of a cross between a Cabbage and a plant of Brussels Sprouts which Swift might have pictured in Brobdingnag, for it was sixty inches high and bore sprouts twelve inches across!

Our Supplement Plate.—With this issue we have pleasure in submitting, as out Supplement Plate, an illustration of the uncommon Aloe supralaevis, Haw., a native of South Africa. In common with other members of this genus, this species, in cultivation, enjoys an average temperature of 60° and dry atmospheric conditions throughout the winter months, during which period the plants should be kept fairly dry at the roots, although during the summer they enjoy ample supplies of water and moist atmospheric conditions. Under cultivation, this species may attain a height of six or more feet, and does not flower until it attains some age and size; the flowers are orange-scarlet in colour, fading to yellow with age. The general habit of the plant is well depicted in the illustration. Although it may be successfully grown to flowering size in a large pot, this Aloe, in common with many of the other species, is only seen at its best when planted out in a well-drained border in a suitable house. Aloe supralaevis, and many other species, are grown extensively at La Mortola, La Selva, and other gardens on the Riviera, finding the conditions there ideal, and attaining a large size. It is easily raised from seeds, when obtainable, or the tops of the shoots may be cut off and rooted as cuttings; quite large shoots may be used for this purpose.

Royal Horticultural Society's President and Council for 1929.—The Fellows of the R.H.S. who attend the Annual Meeting on February 26, in the New Hall, will have before them the following nominations:—President, Mr. Gerald W. E. Loder; Treasurer, Mr. C. T. Musgrave, V.M.H.; Members of Council: Mr. E. A. Bunyard, Dr. A. W. Hill and the Hon. H. D. McLaren; Vice-Presidents, the Duke of Bedford, the Duke of Portland, Viscount Ullswater, Sir James Knott, Sir Daniel Morris, V.M.H., Sir David Prain, V.M.H., the Hon. Vicary Gibbs, V.M.H., Mr. E. A. Bowles, V.M.H., and Mr. J. C. Williams; Auditor, Mr. Alfred C. Harper. The retiring members of Council are Dr. A. W. Hill, Mr. George Monro and Mr. C. G. A. Nix: in its Report for 1928, the Council records its appreciation of the services of these gentlemen, and expresses the hope that Dr. Hill will be elected to serve for another period of years, as he was recently elected under the provisions of the new Bye-laws. The Council also states that it finds a difficulty in appreciating sufficiently the keen interest, enthusiasm and generosity of Mr. George Monro during his term of office, and the long service of many years, almost without interruption, of Mr. C. G. A. Nix, both on the Council and Finance Committee, has been of the greatest value in the conduct of the Society's affairs.

The Late Lord Lambourne.—The Council of the Royal Horticultural Society record with very deep regret the death of The Right Hon. Lord Lambourne, P.C., G.C.V.O., V.M.H., the President of the Society, the loss of whom will be felt by all the Fellows, and friends of horticulture. Lord Lambourne (then Colonel Mark Lockwood) joined the Society in March, 1904, and in 1914 took his seat on the Council. Since that date he took great interest in the activities of the Society, and was elected President in 1919, after the resignation of Field-Marshal Lord Grenfell. He continued to hold this office until his death. In 1926 he resigned his positions on other institutions and devoted himself entirely to the welfare of the Society, attending almost without fail all the meetings of the Council (November 20 being the last occasion). His devotion to the Society and its work, and his geniality and kindness of heart, were all factors in the rapid growth of public interest in horticulture, and under the ten years of his administration the Fellowship of the Society grew from 14,400 to over 26,600. A full obituary will be published in the Society's *Journal*.

The Severe Weather.—The intensely cold and severe weather which has prevailed for some considerable time over a large part of Europe, spread during the early part of this week to the British Isles, and at the time of going to press we are in the throes of arctic conditions, with icy winds, severe frosts, and, in many places, gales accompanied by heavy falls of snow; the weather prophets are very pessimistic in their outlook, and state that there are no signs of an early termination of the cold spell. Great discomfort is being experienced throughout the country, for the frozen roads make travelling a very difficult task, while the heavy snowfalls have also caused considerable traffic delay. In Covent Garden Market the severe weather conditions are reflected in the shortage of salads, the crippled flowers, and in the poor demand for fruits in general, while salesmen experience great difficulty in disposing of their produce even at prices that must be far from profitable for the producers.

[*] *Agricultural Research in* 1927, John Murray, 1928.

[†] Keeble and Pellew, *Jour. Gen.* Vol. 1., p. 10, 1908.

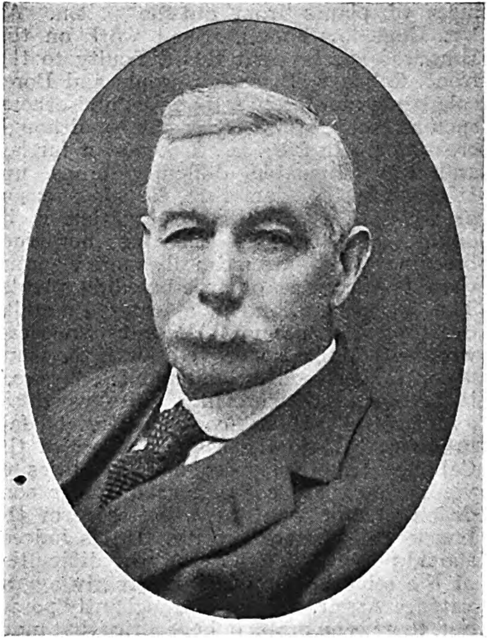
The Iris Society.—The Iris Society is holding its annual show in the New Hall of the Royal Horticultural Society on June 6 and 7. It is expected that the exhibition will contain the largest collection of Irises that has ever been exhibited at one time, and it is proposed that the exhibition should be international in character. Accordingly, deputations have been invited from Iris Societies and Committees in the United States of America, Canada, France, Germany and Holland, and growers in these countries have been asked to exhibit. The Iris show will be opened by His Excellency the French Ambassador at 12.30, and will be followed by a lunch at which the Society will entertain its distinguished guests, and for which members of the Society will be able to take tickets. During the week representatives of the Garden Clubs of America—some 125 persons in all—are visiting the country; they will be invited to the show and will be entertained at tea. In addition to the annual show, the Iris Society holds at least two dinners in the year, which are followed by a discussion; it has published two numbers of an illustrated *Bulletin*, of which Mr. Dillistone is editor. The Society is also drawing up, under the supervision of Mr. Peter Barr, a check-list of Irises, and, under the editorship of Mr. Dillistone, it is preparing for publication the writings of the late Mr. W. R. Dykes, which have appeared in *The Gardeners' Chronicle* and other periodicals. Anyone interested in Irises is invited to join the Society, and apply for particulars to the Hon. Secretary, Mr. G. L. Pilkington, Lower Lee, Woolton, Liverpool.

"Gartenschoenheit" for January.—The January issue of our German contemporary, *Gartenschoenheit*, contains a number of fine coloured plates of Orchids, some of which, being of English origin, will be of especial interest to English readers. Among others, we note Cattleya Fabia, from Dell Park, Englefield Green; and in black and white, Odontoglossum Toreador, from Messrs. Charlesworth's nurseries at Hayward's Heath; Laelio-Cattleya Profusion, from Brockhurst, East Grinstead; and Cypripedium (Paphiopedilum) Baron Opoix, also from Brockhurst. The black and white plates are excellent, and are given every advantage on good, hard-surfaced paper; the coloured plates are pleasing, but not altogether satisfactory, especially as regards the colour of the foliage. The best is, perhaps, Dendrobium thyrsiflorum, which makes a very pretty picture with its yellow and orange blossoms shown against a blue background. Camillo Schneider writes interestingly about modern Orchid-growing, and a number of other articles on various subjects make up the rest of the issue, including one on "The English Park," by Johanna Schopenhauer.

A Hybrid Cotton.—Dr. S. C. Harland, of the Cotton Research Station, Trinidad, B.W.I., writes:—"We have recently made an interesting hybrid between Gossypium Sturtii—a native Australian species, and Gossypium hirsutum, a native American species. I am under the impression that hybrids of native Australian with native American plants are very rare, and should welcome such information on the subject as may be in the possession of your readers."

Concerning Tulips.—We are glad to learn that Messrs. Martin Hopkinson, Ltd., have in preparation "The Book of the Tulip," by Sir A. Daniel Hall, Director of the John Innes Horticultural Institute. This volume, fully illustrated in colour and black and white, is an attempt to bring together the main facts that are known about the Tulip, and is intended primarily for the general gardener and lover of flowers. It is a work which all Tulip lovers will eagerly await, especially from an author who is an authority on the subject, a skilful cultivator, and has "the pen of a ready writer."

Mr. Alexander Malcolm, V.M.H.—Probably no one chosen by the Council of the Royal Horticultural Society to receive the Victoria Medal of Honour in Horticulture has been more surprised than Mr. Alex. Malcolm, of Edrom, Berwickshire, who had "almost forgotten about Sweet Peas," and had no idea his name was being put forward for the honour. When in business at Duns, Mr. Malcolm found relaxation and pleasure in gardening, and many years ago, when Henry Eckford was the leading distributor of novelties, he and a small band of horticulturists took up the cultivation of Sweet Peas with great enthusiasm and success. He exhibited at Edinburgh, and there met Mr. H. Eckford, who did not recognise the variety Miss Willmott, as shown in fine form and colour by Mr. Malcolm. When the waved Sweet Pea—Countess Spencer—arrived, about twenty-five years ago, Mr. Malcolm commenced to raise new varieties and, working on Mendelian lines, obtained many fine results, or, as he puts it, "Time and again, I got almost exactly what I wanted." Like many other people, he tried crossing Sweet Peas with species of Lathyrus, but without success, but on one occasion, using the utmost care, he crossed Cherub (under glass) with the pollen of the common Broom. Two pods formed and showed some resemblance to those of the Broom, but had fourteen seeds per pod. All the seeds germinated, and although no yellow-flowered seedlings appeared, the progeny were extra vigorous, very hardy, fragrant and very wavy. The varieties Renown, George Shawyer and Dignity came from the seeds of one of the pods. Later, Mr. Malcolm raised other varieties, including Royal Sovereign and Grenadier. Undoubtedly a very successful raiser for many years, Mr. Malcolm affords another instance of the success obtainable by an amateur gardener who makes a speciality of one flower and takes a practical and scientific interest in its improvement.



MR. ALEX. MALCOLM, V.M.H.

Gardeners' Royal Benevolent Institution.—This charity will benefit to the extent of about £30 through the activities of Mr. C. H. Cook, of the Royal Gardens, Windsor, who was chiefly responsible for the successful organisation of a whist drive and dance which was held recently in the Windsor Guildhall. A party of about three hundred assembled, and it was generally agreed that the event was a great success. Mr. Cook is to be congratulated upon his active interest in this charity, and it is to be hoped that other prominent gardeners will follow his splendid example.

Bracken Disease in Scotland.—Professor K. W. Braid, of the Botany Department, West of Scotland Agricultural College, informs us that since we published an account of his investigations in the control of Bracken, in our issue for January 29, p. 56, he has had a number of letters from readers of *The Gardeners' Chronicle*, and he and his co-worker, Mrs. N. L. Alcock, are looking forward to receiving observations from some of them during the course of the year. He also informs us that the pamphlet referred to in our note is not published by the West of Scotland Agricultural College, but is a reprint from the *Scottish Forestry Journal*.

The Temperate House at Kew.—It is pleasant during the dull, cold days of early February, to leave the outdoor garden and enjoy a display of forced, early-flowering trees and shrubs, such as may now be seen in the Temperate House at Kew. They are grown in large pots and thinly dispersed among the Tree Ferns and other foliage plants, the effect thus obtained being extremely delightful. Notable subjects in flower at the present time include Magnolia Soulangeana and M. stellata; a considerable number of plants of Prunus triloba plena, with dainty, rich pink blossoms; Pyrus floribunda and P. Scheideckeri; the beautiful Forsythia spectabilis, Staphylea colchica, and Rhododendron sinense, better-known, perhaps, as Azalea mollis.

Richmond Park Golf Pavilion.—We understand that a scheme is being considered by the Office of Works in connection with the extension of the golf pavilion at Richmond Park. It is announced that the need for such extension is particularly noticeable in the summer months, the two public golf courses being so popular that players occasionally have to wait for periods of from one to three hours before their turn arrives to start. Over 100,000 rounds are now played on these courses in a year.

R.H.S. Awards of Garden Merit.—Seven plants are recorded in Vol. LIV, Part 1, of the *Journal* of the Royal Horticultural Society, as having received the R.H.S. Award of Garden Merit. They are: Crataegus × Carrierei (December 8, 1925), a Thorn which was described by M. E. A. Carrière in *Revue Horticole*, 1883, p. 103, figures of both the flowers and fruits being given in colour. It was raised from seed of C. mexicana (syn. C. stipulacea), which species it strongly resembles, and is a strong-growing small tree or large bush, producing large corymbs of white flowers during late May and June. These are succeeded by rather large, orange-red fruits which remain on the tree some considerable time and, in conjunction with the rich autumn tints of the foliage, impart to it a very striking and attractive appearance. Polygonum Aubertii and P. baldschuanicum (October 8, 1928), rank among the most beautiful of climbing flowering plants, and it is a controversial point as to which of these two subjects is the most beautiful. Their distinguishing characters are not very pronounced, both producing panicles of pink-tinted flowers, the panicles of P. Aubertii being narrower than those of P. baldschuanicum, while the flowers are often not so pink and are sometimes tinged with green. They are both ideal subjects where free-growing climbers are required for the covering of pergolas, etc. Sedum spectabile (October 3, 1927) is a well-known and popular herbaceous perennial, flowering, as it does, when the majority of herbaceous plants are past and remaining attractive well on into October. There are several varietal forms of it, notably Brilliant and atropurpureum, both of which have darker flowers than the type. Prunus Davidiana alba (January 23, 1927), belonging to the Amygdalus section of Prunus, is a deciduous tree of great beauty, and is described as hardy in the south and mild parts of the country, but requiring a sheltered position in bleak districts. There are two forms, one with rose-coloured flowers, and the other with white; the latter is considered the more decorative of the two and has therefore received the Award. Phacelia campanularia (July 4, 1927), is a desirable annual of easy culture; it bears large, widely bell-shaped flowers of deep gentian-blue, producing them, when grown well, over a long period. It is hardy and seeds may be sown during autumn or spring where it is to flower. P. campanularia is a native of California, and was described in *The Gardeners' Chronicle* so long ago as 1882 (Vol. XVIII, p. 51). The last plant described as having received the Award is Scilla siberica, already a popular bulbous subject in gardens, which, having once been planted—in autumn—will look after itself and flourish and increase. It is later-flowering than Scilla bifolia, and has larger and more open bell-shaped flowers, which are of a deeper blue; there are several forms of it, variety atrocoerulea, sent to Wisley by Messrs. van Tubergen, of Haarlem, being considered the best, although both the white and the pink forms are well worth growing.

Easier Access to Wisley Gardens.—Fellows of the Royal Horticultural Society living in and about London, who have not been able to visit Wisley Gardens very frequently owing to the difficulties attached to getting there, will be pleased to learn that a new express motor-coach service has been started between London and Guildford. The service has been organised by the Skylark Motor Coach Co., Ltd., and the coaches will leave the respective termini, North Street, Guildford, and Oxford Circus, London, at intervals of an hour from 7.30 a.m. to 10.30 p.m., from Guildford, and to 11.30 p.m. from London. The single fare is 2s. 6d., and the return fare 4s. 0d.; these charges compare very favourably with those of the railway. The journey from London is made via Marble Arch, Shepherd's Bush, Hammersmith, Esher, Cobham and Ripley, and passengers may board the coach or alight at any place *en route*. Time-tables and full particulars of the service may be obtained from Roxburgh House, 281, Regent Street, W.

English Roses in Paris.—In a letter to our French contemporary, *L'Horticulture Francaise*, M. Albert Maumené writes lamenting the extent to which foreign flowers are imported into France and sold in Paris, to the disadvantage of French growers. *Inter alia*, he states: "Already, the Paris florists are offering Roses and Lilac from Aalsmeer; Roses of a still better quality, more durable and with a better appearance, are arriving from English hothouses; although having to be bought at the unfavourable rate existing between the florin and the franc, and the pound and the franc, respectively." M. Maumené draws from all this the moral that French growers are not sufficiently alive to their own interests, and he urges them to produce sufficient flowers for their own markets, instead of letting the foreigner in to take the best of the trade; but, incidentally, it is pleasant to have his unbiassed opinion of the English Roses exported to the Paris markets.

Small Holdings in Germany.—The local authorities in Berlin are considering the purchase of a large estate known as Damsdorf, about fifty kilometres from the city, for the formation of small holdings. Several large farms and some smaller ones will be established, and also sixty market gardens for the cultivation of hardy plants and other subjects. The smaller gardens will be handed over to the cultivators with forcing houses and heating apparatus all complete, the large ones with a part of their area ready planted with Asparagus. Oberbürgermeister Böss, who is an expert in the preparation and organisation of these state holdings, is planning to have a ring of them all round the outer margin of the capital, and the success of those already established is encouraging the local authorities to proceed apace with their plans.

Legacies to Gardeners.—The late Mr. H. C. Tower, of Eton Cottage, Staines, who died on November 14, 1928, left £50 to his gardener, Mr. George Parsons.—The late Col. Charles J. Goer, of Ashby Road, Winshill, Derbyshire, who died on November 30, last, left £100 to his gardener, Mr. William Harold Coltman, V.C.—The late Mr. James Nicholson Stuart, of Broomhall, Harrow, Middlesex, who died on December 20, 1928, left £250 to his gardener Mr. Arthur John Fuller, and £5 for each year of service from January, 1923.—The late Mr. Arthur William Page, J.P., of Rockstead, Bournemouth, who died on November 28 of last year, left £500 to his gardener.

Mr. F. L. Engledow.—We learn that Mr. F. L. Engledow, of St. Johns, Cambridge University, reference to whose work in connection with plant breeding is made in our leading article of this issue, has been appointed a member of the Council of the National Institute of Agricultural Botany until February, 1931.

Kew versus Wisley.—On Saturday, January 26, a football match took place between teams representing the Royal Botanic Gardens, Kew, and the R.H.S. Gardens, Wisley. Playing on the ground of the latter, Kew started with a strong wind in their favour, and scored first, but Wisley replied, and at half-time the score was one all—Kew were unfortunate in losing a man through an injured ankle. In the second half Wisley played with the wind, and although attacking most of the time, were unable to score again, thanks, chiefly, to the excellence of the opposing goalie. Kew, however, added two more goals, and the game thus ended with three goals to one in their favour. The game was played keenly throughout, and will, it is hoped, be the first of many such encounters between the two Gardens. The match was followed by tea, at which the Kew captain expressed his appreciation of Wisley's sport and hospitality, and the desire of his team to return the compliment at Kew. Mr. J. Reid replied for the home team. Messrs. Stedman, Arnold (captain), Bate, Hildyard, Hewitson, Bond, Boyce, Bilstrom, MacGregor, Slinger and Davis played for Kew; and Messrs. Ockamore, Hardwick, Mulligan, Green, Fletcher, Wood, Lawrence, Peters, Reid (captain), Phillips and Horton formed the Wisley team.

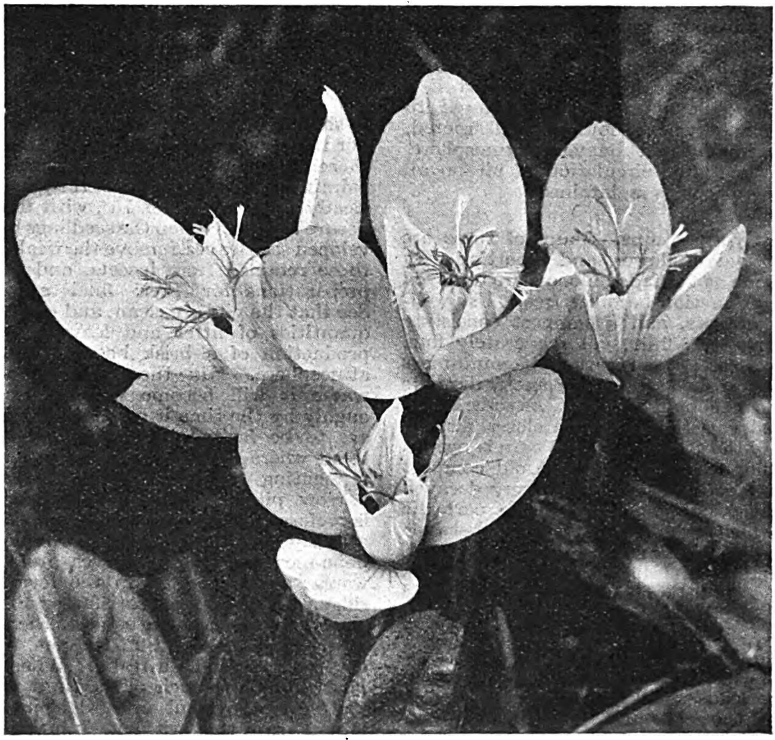


FIG. 58.—CROCUS IRIDIFLORUS.
(see p. 116).

Appointments for the Ensuing Week.—Monday, February 18: East Anglian Institute of Agriculture lecture; British Industries Fair. Tuesday, February 19: Winchester Horticultural Society's meeting. Wednesday, February 20: Wimbledon and District Gardeners' Mutual Improvement Society's meeting. Thursday, February 21: Ipswich Gardeners' Association's meeting. Friday, February 22: Sundridge and Braster Society's meeting. Saturday February 23: Leeds Paxton Society's Bulb Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Royal Botanic Garden, Dublin.*—We learn from the Curator's last annual report that there is now every prospect of this garden possessing a proper house to grow and flower the Victoria Regia and other tropical aquatic plants in, and also a museum of economic botany. An iron house, which was erected for a temporary purpose on the ground now occupied by the building of the great Industrial Exhibition, has been converted into a museum building, and now occupies a suitable position in the garden. It is certainly not the most appropriate structure for this purpose, but it will suit well as a commencement; and "I have," says Mr. Moore, "little doubt that so soon as the Government and the public see the importance of this department, sufficient means will be provided to make it as creditable as the museums attached to the Botanic Gardens at Kew and Edinburgh, which have been constituted at the public expense." Some of the glazed cases to hold the various articles are in course of construction, and a very considerable collection is already in store to furnish them, consisting of vegetable fibres, barks, gums, oils, etc., used in medicine, the arts, and manufactures, besides various preparations of vegetable products used as food, and fine sections of woods, etc., all of which have been purchased from the British Guiana Department of the Industrial Exhibition. Considerable donations have also been made from other departments in the exhibition. The proceeds of a garden fête, at which nearly 4,000 people attended, have enabled the Committee of Botany to undertake the erection of a fine stove aquarium house, which is now progressing satisfactorily, and will be ready for the reception of plants early next spring. *Gard. Chron., February* 18, 1854.

Publications Received.—*The Problems of Applied Entomology*, by Robert A. Wardle, M.Sc., pp. 587; The Manchester University Press; price 30/- net.—*Irises*, by F. F. Rockwell, pp. 84; The Macmillan Company, New York and London; price 4/6 net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Autumn- and Winter-flowering Cypripediums.—These are very popular and are being grown in large quantities for the production of cut flowers and for general decorative work, while the production of many fine and improved forms by various raisers has made them of general interest to the connoisseur. The lasting qualities of the blooms, both on the plant and when cut and placed in water, are well-known, while they are not easily damaged by fogs, a great asset when the collections are grown in smoky districts. Numerous varieties are now available at moderate prices, and these include many fine, long-stemmed and highly-coloured forms, all of which will thrive in the intermediate house in a position where moist conditions may be afforded throughout the whole year. If a minimum temperature of 55° can be maintained, only sufficient shading is necessary to prevent the sun from scorching the foliage, for flowers of fine quality are produced if a reasonable amount of sunlight is allowed to reach the plants when they are well rooted, provided a humid and buoyant atmosphere, kept sweet by a free circulation of air on all favourable occasions, is maintained.

Repotting Cypripediums.—Many of these are now passing out of flower, and repotting may be done so soon as the faded blooms are removed and before root-action becomes free. Use well-drained, clean pots, and a compost consisting of equal parts A.1. fibre, cut moderately fine, and fibrous loam; one part Sphagnum-moss and plenty of crushed crocks; in smoky districts a little less loam should be used. As some of the strong-leaved varieties are much closer growers than those of the C. insigne type, care is needed when dividing the growths. The old compost should be removed with care and any decayed roots cut away before attempting to part the rhizomes, which should be separated between the second and third growths from the lead, so as to induce the back growths to break more readily. A little powdered charcoal should be dusted on the severed parts to prevent rhizome rot. If large specimens are desired—Cypripedium flowers are seen to their best advantage when displayed in this way—some of the leads should be arranged towards the centre of the receptacle, keeping the base of the plant just below the pot rim, and working in the potting material—which should be warmed previously—carefully and firmly among the roots. In districts where the water tends to make the loam sour on the surface, a little extra fibre and moss may be used as a finishing layer, and a few crushed crocks sprinkled over the surface will help to keep it sweet. If the soil is moistened through after repotting, only small quantities of water will be required at fairly long intervals until new roots are moving freely, although sufficient is necessary to keep the old roots from shrivelling; the quantity of water required will depend on the amount of fire-heat employed to maintain the required temperature. Humid surroundings should be maintained by damping the paths and lower stages, also by occasionally syringing between the pots during favourable weather. When well established, the plants require ample supplies of water at the roots each time the compost appears dry, although constant saturation should be avoided.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Spring Cucumbers.—Where winter plants have failed, or are not grown, an early start with stout, young Cucumber plants is of great importance. Cucumbers delight in a compost of rich turfy loam, a little leaf-mould and rough lime-rubble. Good drainage is essential, as the plants will require an abundance of water, while they will need a bottom-heat of about 80°. They do well in pots plunged in a bed if room is scarce, but, other conditions being satisfactory, the best and largest returns are obtained from specimens planted out in ridges of good compost, somewhat heavier than that recommended for use through the winter. No manure should be used in the compost, as this only encourages worms, and does not maintain such steady growth as may be secured from good compost, augmented by applications of warm, diluted soot and guano water. Sow the seeds in the same way as recommended in my notes for January 5. A very important point in the management of spring-sown Cucumber plants is the placing of them in their fruiting quarters before they become pot-bound, as root-bound seedlings are of little use; they should be planted out so soon as the rough leaves appear, provided, of course, the soil is warmed through for their reception.

Melons.—Very early Melons, which are in pots, should receive a steady night temperature of 70° to 75° on mild nights at this season of the year, and it will be advisable to augment the bottom-heat with more litter and leaves, the warmth from these being more genial than that from hot-water pipes alone. More seeds should be sown if efficiently heated pits are available. For this purpose good early varieties should be chosen, and the seeds should be sown singly or in pairs in small pots or cubes of turf, and placed in a steady bottom-heat of 75°, with the fullest exposure to light. When the seedlings have fully developed seed leaves, remove the weakest; protect those retained from insects, and push forward preparations for their final accommodation. See that the pits are clean, and prepare sufficient quantities of litter and leaves for aiding the production of a brisk bottom-heat and moist atmosphere. Mix the compost and place it where it will become warmed through thoroughly by the time it is required. If the plants are to be fruited in twelve-inch pots, plunge them where they are to remain, and place the fermenting material around them. Where narrow pits are at command and planting-out is preferred, the same type of compost, consisting of fairly heavy loam, old lime-rubble and a little bone-meal, placed on turves grass-side downwards, and raised up in the form of a sharp ridge, should prove satisfactory; but unless the hot-water pipes are equal to the maintenance of a bottom-heat of 80°, the pot plants will be the first to ripen their fruits. When established, place a stick to each plant, tie it to the trellis, and train the plant upwards, pinching out all lateral growths without injuring the main leaves, but defer stopping the plants until two-thirds of the wires are covered. Keep a stock of warm compost at hand, and apply it frequently in small quantities as the roots appear on the surface of the soil; it should be rammed firm. The night temperature for these should be 66° to 70°, and the day temperature, 75° to 80°, allowing a rise of 10° from sun-heat. Maintain a moist, growing atmosphere by frequent sprinklings of water, but avoid wetting the foliage except on bright days, until the plants commence to cover the trellis.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Planting Trees and Shrubs.—As better weather conditions prevail, every endeavour should be made to complete the planting of deciduous trees and shrubs before the end of the month, if this work has not already been finished. By so doing, there will be less risk of loss from drying winds in spring. When selecting subjects for planting, consideration should be given to trees and shrubs that flower late in the summer, while those that have richly-tinted foliage in autumn, or brightly-coloured stems in winter, should also be taken into account. These points should be kept in view by those responsible for planting, so that the interest of the garden may be increased during autumn and the dull, short days of winter. Shrubs which take on brilliant colouring during the autumn include Cornus Kousa, Cercidiphyllum japonicum, Euonymus alatus, E. yedoensis, E. europaeus, Pyrus floribunda, Amelanchier canadensis, Acers in variety, and all forms of Enkianthus. Berberis vulgaris, B. Thunbergii, B. yunnanensis, B. Jamesiana, B. Wilsonae, and many of the new Berberis hybrids, if included, will brighten up the garden in the autumn. Where peaty soil is available, Vaccinium corymbosum, V. pennsylvanicum, Pieris Mariana and numerous varieties of Azaleas will be found of great value for autumn effect. Trees that have brightly-coloured foliage in autumn should be planted freely where sufficient space is available, and should include Quercus coccinea, Oxydendrum arboreum, Taxodium distichum, which should be planted near the water, and Liquidamber styraciflua, which requires a similar position. Parrotia persica, more often seen as a bush than a tree, has bright crimson and gold autumn foliage, while many of the Prunuses and Pyruses are as valuable for their autumn colouring as for their spring flowers. Crataegus Crus-gallii, C. prunifolia, and many others belonging to the Crus-gallii group of Thorns, give great satisfaction where autumn colour is appreciated.

Trees and Shrubs with Coloured Stems. Shrubs with brightly-coloured stems for winter effect have been sadly neglected by planters in the past, yet there are many suitable for producing a bright and pleasing effect if judicious grouping of the various subjects is practised. For positions near the water's edge, none are more valuable than the numerous Willows and some of the Cornuses, but to secure the best effects with these they should be cut hard back early each spring to induce them to make plenty of young, vigorous shoots, as their bark loses its bright colouring after the first year. A few of the best of the Willows include Salix vitellina, S. coccinea, S. pruinosa and S. daphnoides, while Cornus alba atrosanguinea is one of the most striking of the red-barked Dog-woods. C. stolonifera var. flaviramea is as equally effective with its yellow-coloured bark. Such varieties of Berberis as B. yunnanensis, B. Jamesiana, B. dictyophylla and B. virescens, add colour to the garden during winter with their coloured stems, as well as in summer and autumn. Among species of Rubus, many of the white-stemmed forms are effective for grouping, R. biflorus and R. b. var. quinqueflorus being two of the best. There are numerous shrubs whose young shoots are an attractive green or brown during winter, which should be planted if room permits; these include Forsythias, Lycesteria, Kerrias, etc. Of trees with coloured trunks and stems, none is more valuable than the Birch, and our native species is probably still the best. Others that are worthy of a place to provide variety are B. papyrifera, B. lutea, B. Ermanii, B. occidentalis and B. nigra.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

Cherry and Plum Blossom Wilt and "Wither Tip."—This disease is becoming a very serious danger in many private gardens and orchards. As the spores are carried over on the dead young wood of the previous year, it is imperative that every particle of these infected shoots should be cut away well below the diseased portion, and the trees sprayed with lime-sulphur at winter strength, *i.e.*, one in twenty. This disease attacks both the Sweet and the sour Cherries, and most Plums, particularly the varieties Victoria, Belle de Louvain and Pond's Seedling. Infection spreads, as with Apple blossom wilt, through the open flowers, to the leaves, and eventually to the growing shoots. The disease is considerably more virulent in dull, cold seasons when the trees are in bloom, and but a few bees are about to assist in pollenation. The foregoing treatment will also help considerably in the eradication of Cherry fruit scab (Fusicladium cerasi), which forms dark blotches on the ripening fruits. These blotches vary in size and number, rendering the fruits unfit for use.

Orchard Trees.—There are many old orchards throughout the country which were planted with mixed fruit trees many years ago as an adjunct to the garden or homestead, and are now in a more or less neglected condition. There are many inexpensive remedial measures which may be applied during the dormant season which would rectify this state of affairs. The most important is to see that the drainage is good, and, if not, to remedy it, as there is nothing so conducive to canker and other diseases of fruit trees than a badly drained soil. The next is to ascertain which of the trees are still bearing useful crops of fruits, and which may be improved by careful thinning of the branches, a good cleansing wash, and the application of suitable manures. There will be others which, although healthy, may be bearing inferior fruits, and these are best headed back to convenient points to be top-grafted later in the spring. Then there may be a number beyond all hope of recovery; these should be destroyed. Where these veterans are to be replaced by young trees, it is essential that the station for each new tree should be prepared thoroughly. The old soil should be replaced by fresh material to which lime, rubble and chalk have been added, according to the texture of the soil. The top-soil, to the depth of a foot and a surface area of six square feet, should be removed, and the subsoil broken up thoroughly to the depth of another foot to ensure drainage. There is always a grave danger, especially in retentive clay soils, that these stations may become basins in which water will collect. The only remedy in such cases is to run tile drains from these basins to the nearest ditch.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hatfield, Hertfordshire.

Asparagus.—Asparagus plumosus, A. Sprengerii, and other sorts, are invaluable for decorative purposes, either in the cut state or as specimen plants. A Sprengerii and A. decumbens are invaluable when grown in hanging baskets suspended from the roof, but under these conditions need to be soaked periodically in a tub of water. All the species may be raised from seeds, which should be sown in a warm house; if the seeds are soaked in warm water for twelve hours prior to sowing them, their germination may be hastened. The seed pots should be plunged in a warm case provided with plenty of heat; if new receptacles are used they should be soaked for a short time before sowing the seeds. So soon as the seedlings are large enough to handle they should be pricked off singly into small pots, and when of suitable size should be transferred to larger receptacles or baskets, according to requirements. Here, A. plumosus and its varieties are planted out in small borders against the back walls of a warm pit and vineries, and in such positions it grows luxuriantly and produces sprays in quantity for cutting purposes. All the species are free-rooting and delight in ample supplies of water, with liberal feeding at the roots.

Trachelium caeruleum.—This subject is very suitable for growing in pots, as it may be had in flower over a long period by raising a succession of plants from seeds. Plants from seeds which were sown last autumn should now be ready for potting on into forty-eight-sized pots. T. caeruleum requires no special compost, provided the plants receive some assistance from liquid manure when they have filled their receptacles with roots. If seeds are sown now, and the seedlings grown on into forty-eight-sized pots, they should make useful specimens for furnishing the plant stages of the conservatory during the autumn. To obtain larger specimens, plants which were cut down last year should be grown on into eight- or ten-inch pots.

Coleus thyrsoideus.—Specimens of this subject which have passed out of flower should be cut hard back with a view to obtaining good, stout cuttings for propagating purposes at a later date. C. thyrsoideus may also be raised easily from seeds. From seeds sown now in a light, sandy compost, good flowering specimens may be obtained for next winter's display; the seeds should be lightly covered with fine soil and placed in a temperature of 60° to 65°.

General Remarks.—Late-flowering Chrysanthemums may now receive attention with regard to propagating. Select basal growths about three inches in length, and insert them in an open compost. At this season of the year they should root quickly if placed in a close case in a cool house. Continue the propagation of Carnations to produce plants in succession to the earlier-rooted ones. If the early rooted plants have filled their receptacles with roots, they should be potted on.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Autumn-sown Onions.—The ground in which these have to be planted may be forked lightly and the surface raked to a fine tilth. It should be trodden firmly and levelled, after which the plants may be put out, six to eight inches apart, in lines fifteen to eighteen inches apart. Extra large and strong seedlings should be discarded, as these invariably "run to seed."

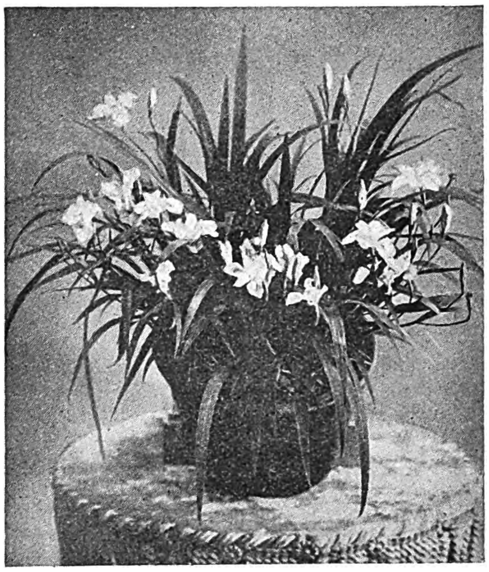

FIG. 59.—IRIS GRACILIPES.
(see p. 116).

Cabbages.—To provide a succession to the established beds, another batch of autumn-sown Cabbages may be planted now. The ground in which they are to be placed should be forked lightly, after which the lines should be marked with drills made with a draw hoe; for the stronger-growing varieties a distance of eighteen to twenty inches should be allowed between the lines, and for smaller varieties, sixteen inches. Select the best plants from the seed-beds so that they will all be a uniform size when in growth. Should slugs be troublesome, a sprinkling of slaked lime or spent carbide placed around the necks of the plants, should keep them in check.

Shallots.—These may now be planted in drills one foot apart and two-and-a-half inches deep, pressing the bulbs in the shallow furrows at intervals of eight inches to nine inches. When planted, the soil between the lines should be worked with the Dutch hoe a certain amount of soil will close around the Shallots and so keep them firm. Birds may prove troublesome when the bulbs commence growth, and a watch should be kept that none becomes displaced.

French Beans.—Dwarf Beans in pots will now require some support. For this purpose thin twigs of Birch are suitable, or four stakes may be used and connected with raffia. Never allow the plants to fall over. Syringe them overhead at least once each day, and on bright days admit plenty of fresh air, especially when the plants are coming into flower. Never allow the plants to suffer from lack of water. When the pods are about one inch long, give applications of liquid manure once each week.

Parsnips.—The ground in which Parsnips are to be grown should be dug deeply or, if possible, trenched, breaking up the subsoil with a fork. The deeper the soil is dug, the better, but, if exhibition specimens are required, they are best grown in holes bored with a crowbar as deeply as possible, and filled with finely sifted soil. The holes should be filled carefully, care being taken to leave no pockets, as these will cause the Parsnip roots to twist and so ruin them from an exhibition point of view. Provided the ground is in suitable condition, the seeds may be sown any time during February, sowing three or four seeds in each hole, the resultant seedlings being thinned to one—the strongest. Applications of liquid manure should be given occasionally to encourage the development of large roots.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemount, Monkton, Ayrshire.

Sweet Peas.—If seeds of Sweet Peas were not sown in the autumn, they should now be sown in pots or boxes. I prefer sowing Sweet Peas in ordinary seed-boxes and potting the seedlings singly, or mossing them, after the seedlings have been stopped and have broken into growth again. The seeds may, of course, be sown in the open ground where they are to flower, but few follow this method now-a-days, and it is not to be recommended.

Dahlias.—The stock tubers of these should now be placed in a good brisk heat to start them into growth if a large supply of cuttings is required, but where a large number of plants is not required, the tubers may be started slowly, divided into the required number of plants, and potted up.

Planting Bulbs, etc.—Ranunculi, Gladioli of the Colvillii type, and Anemones for late flowering, may now be planted if the soil is in a favourable condition. On heavy land the bulbs or corms, as the case may be, should have a little sharp sand placed around them, or they may rot should a protracted spell of cold, wet weather be experienced.

Malmaison Carnations.—Established specimens of these will now be showing signs of growth, and should be staked and have all dead leaves removed. A dressing of Carnation fertiliser, or a small quantity of rich soil, should be given, but on no account should the neck of a plant be buried deeply. Water them with care at all times as they prefer a moderately dry root condition, and keep them in a cool house, well exposed to light, but shaded during the hottest part of the day, in warm, sunny weather.

Potting.—Many subjects will now require attention with regard to potting. Zonal and Show Pelargoniums from cuttings rooted last autumn, will now require more root-room, and should therefore be repotted into larger receptacles. A compost of three parts good loam and one of old manure, with a little lime-rubble and sand added, should suit them well for the final shift into their flowering pots, but for earlier pottings a lighter mixture, with a little leaf-soil added, should be used.

ORCHID NOTES AND GLEANINGS.

EPIDENDRUM VITELLINUM.

Both the summer- and autumn-flowering varieties of this brightly-coloured Mexican Orchid thrive under similar conditions to those afforded Cymbidiums. When in active growth they revel in sun-heat, with plenty of fresh air and moist conditions, but after growth is complete and flowering has finished, very little water is required at the roots until growth is again active; while resting they require just sufficient moisture to keep them in a sound condition, without exciting them into growth too soon.

Specimens that have been resting under cool conditions should be examined frequently, and directly the new roots are noticed developing from the base of the last made pseudo-bulb, any plants that require fresh rooting material should receive attention, as if repotted at this stage there is less danger of injuring the fleshy roots than there is at a later date when growth is more advanced. After repotting, water should be afforded sparingly at fairly long intervals, especially if the house in which they are growing is kept moist. When roots and growth are well advanced, copious supplies of water will be needed each time the compost becomes fairly dry, which will be governed by the amount of sunshine that reaches the plants. E. vitellinum should not be shaded heavily at any time, a light blind being sufficient in the hottest weather, provided abundance of air is admitted.

When repotting specimens, well-drained receptacles should be used, while the compost should consist of Osmunda or coarse Al fibre, used in a fairly rough state, a little fresh Sphagnum-moss and broken charcoal. Firm potting is essential so that the water may drain away quickly; if the compost is left in a loose state around the roots, it will absorb water like a sponge and retain it a long time, so that the compost soon becomes sour. A small white scale often attacks plants of E. vitellinum, damaging them especially around the growing points, and they should be removed so soon as detected. *W. G.*

INDOOR PLANTS.

IRIS GRACILIPES.

Although by no means difficult to grow in the open garden, in a selected position on the rock garden, or in a warm border, Iris gracilipes is undoubtedly seen at its best when grown as a pot plant (Fig. 59) in a cold greenhouse or alpine house.

For this purpose it should be potted or placed in pans during the summer, while it is in active growth—at which period it is safe to divide the rhizomatous growths—in an open compost of loam, leaf-mould (only very little), and sand. The plants should be placed in a cold frame to become established, and grown on naturally, no attempt being made to force them into flower with the aid of artificial heat.

Iris gracilipes, from Japan, is one of the most dainty of Irises in cultivation. It forms a dense tuft of grass-like leaves, up to one foot in length and one-third-of-an-inch wide, and from among these are produced, on wiry, slender stems eight inches or more long, the delicately fringed flowers; no description fits these blooms more aptly than that employed by the late Reginald Farrer, in his *English Rock Garden*, who wrote eloquently of them as "wide-winged, delicate butterflies in the tenderest crumpled silk of pale-blue, with beard and enrichments of gold, and a pale veined eye."

I. gracilipes is now in commerce in this country, so there is no reason why all who are lovers of beautiful and daintily-flowered plants should not attempt its culture, if not as a pot plant, then in the open garden. The illustration on p. 115 represents a plant grown by Mr. A. Unger, at Heidelberg. *F.*

ALPINE GARDEN.

OXALIS TETRAPHYLLA.

One of the Oxalises, or wood Sorrels, which is classed as hardy, although it is not absolutely so in all parts of this country, is Oxalis tetraphylla, of which O. Deppei is probably only a variety. It comes from Mexico, the native land of several of the host of plants of this class. Its height is given as six inches, but it frequently exceeds this. The root-stock, called by gardeners the "bulb," is top-shaped, and the leaves, which are of fair size, are composed of four leaflets. The flowers are quite handsome, and the colour description of "lurid red," or "lilac-purple" hardly does them justice.

Like the majority of these exotic Oxalises, O. tetraphylla requires a light soil and a sunny position; in a sunny moraine it thrives well. O. tetraphylla is offered by some nurseries, and may be found in their catalogues under the name of O. tetraphylla or O. Deppei. It may be planted in spring or autumn, the former preferably, but if autumn-planting is followed, the plant should be covered with some litter or ashes during the first winter at least. *S. Arnott.*

LINARIA ORIGANIFOLIA.

Opinions are divided as to the merits of this subject as a garden plant; some affirm that it is desirable and well worth its place in the alpine garden or on the rock wall; others state that, owing chiefly to its lack of brilliance in colouring, it is not worth growing.

Personally, I am of the former group, for I consider that, if given a suitable situation, and provided the summer is at all favourable to the production of flowers, L. origanifolia is well worth its place, for although admittedly lacking in clearness and brightness of colouring, this deficiency is amply compensated by the freedom with which the blooms are produced.

In the first instance, L. origanifolia is a sun-lover; it cannot be expected to give of its best unless planted in a sunny, and comparatively dry position—the ideal is a warm crevice on a sunny cliff or rock bed. It is a perennial, but seldom long-lived, in fact, it is best treated as an annual, for it usually flowers with such abandon that its vitality is sapped and it invariably dies during the winter. However, it provides an abundance of seeds, and self-sown seedlings appear in plenty. These may either be left to grow where they have arisen, or may be transplanted carefully to suit able positions.

L. origanifolia is a native of southern Europe. It forms a bushy plant of rather weakly growths, six or eight inches long, clothed with small, oblong or obovate, short-stalked leaves, tinted to a greater or lesser degree with purple, according to the position and the weather conditions prevailing; the lower leaves are oppositely, and the upper alternately, disposed on the growths. From mid-summer onwards, until well into the autumn, these growths are terminated with loose racemes of small, purplish-violet flowers, of varying depth of colour and sometimes very pale, with yellow throats. As previously stated, they are not by any means brilliant, but when the plants are literally hidden beneath them, as they often are, they cannot fail to produce a most charming effect. If, by chance, a seedling with flowers of richer colouring is obtained, with care it may be increased by cuttings, which should be wintered in a cold frame under fairly dry conditions.

ISOPYRUM THALICTROIDES.

In appearance not unlike a dwarf Thalictrum, Isopyrum thalictroides is a dainty and unimposing little subject for planting in cool, semi-shaded positions on the rock garden or near woodland paths, in a cool mixture of peat and loam, although it is not very particular in the matter of soil, and is quite easy to establish.

It is found naturally in the woodlands of central Europe and Switzerland, and is therefore quite hardy, being among the earliest of alpine plants to commence growth. A member of the Order Ranunculaceae, in early spring it forms compact little clumps, six or eight inches high, of dainty, Maidenhair Fern-like foliage, bright green and very charming, while during March the light, open sprays, about nine inches high, of pearly-white blossoms, are produced. When these are finished the plant is so unobtrusive that it seems to fade away and attracts no more attention until the following spring. It is a good perennial and may be increased quite readily by careful division, while seeds are sometimes offered by seedsmen and from these plants are easily raised.

Although laying no claim to being at all striking in appearance, I. thalictroides is of such dainty appearance that it might well be given a trial, especially as it produces its flowers so early in the year. *W.*

BULB GARDEN.

CROCUS IRIDIFLORUS.

Among the most distinct species of Crocus known to cultivation is C. iridiflorus (Fig. 58), whose fully expanded flowers, as its name suggests, resemble those of an Iris to a marked degree; it has been described by several authorities under the name C. byzantinus, and was, indeed, figured in the *Botanical Magazine*, t. 1,111, under this title; while, on account of its peculiarly shaped flowers, it was placed in a separate genus by Schur, and given the name Crociris iridiflora. However, it is now generally known as Crocus iridiflorus, certainly the most suitable name, for it is not Byzantine in its habitats, being found in Hungary and Transylvania, while it is certainly a Crocus, and therefore is entitled to its generic name as such.

The outer segments of the flowers are twice the length of the inner ones, being about two inches in length and one inch wide, and of rich purple colouring; the inner segments are much narrower and pointed, much paler than the outer, in some instances nearly white, and with purple veins. This Crocus is also distinct from the other species in that it has pale purple stigmata, which are divided into slender threads.

There are several grand varieties of this Crocus, including a pure white form which has pale yellow stigmata; and, among those raised by the late Mr. Allen, of Shepton Mallet, there are President, with large, deep purple blooms; Rosamund, pale lilac, and Ruby, reddish-purple.

Crocus iridiflorus is by no means difficult to grow, for it is of robust constitution, and, being a native of woodlands, delights in semi-shade and a compost containing plenty of peat and leaf-mould. *G. F.*

HARDY FLOWER BORDER.

HEUCHERAS.

Not many years have elapsed since the Heucheras, or, at least, the few that were then known, were regarded as only second class border plants, but recently they have received considerable attention from the florists, so that now we have a group of beautiful forms which rank among the finest of plants of medium stature for the front of the herbaceous border. Their foliage alone is sufficiently attractive to recommend them for cultivation and, whereas the species are often unsuccessful in some gardens, failing to remain of long duration no matter what conditions are afforded them, many of the striking hybrids, in themselves vast improvements on the types, have overcome this failing and are indeed first-class plants.

H. sanguinea is the best-known of the species and is, in itself, very attractive, but in the hands of the specialist it has given rise to variations, in a large range of colours, of even greater merit. The form Pluie de Feu, for instance, which has now been grown for some considerable time and was one of the first forms of H. sanguinea introduced, is one of the finest, although now not so easy to obtain; its foliage is very attractive, a trait associated with all the Heucheras, while the fiery-red, very striking flowers are produced with freedom. Edge Hall variety is well worth securing, its blooms being of a distinct shade of coral-pink; the variety splendens produces, in long succession, strong spikes of large, bright crimson flowers; while variety maxima is a bold flowering variety, its blooms being of a rich shade of coral-red. The so-called variety alba, whose greenish-white flowers change to pink, has been replaced by the form White Empress, while other varieties of outstanding garden value are Miss Jessop, with slender spikes of bright, rosy-crimson blooms, produced very freely; Walker's variety, one of the best, with spikes up to two-and-a-half feet tall, heavily laden with large, vivid crimson flowers, and Roi des Violets, with bold inflorescences of rich, ruby-crimson, the flowers becoming tinged with violet as they age.

H. Rosamundi, a hybrid between H. micrantha rosea and H. sanguinea, is still one of the best, its tall, branched stems, bearing rich, coral-pink flowers, being very useful for decorative purposes when cut. H. gracillima, also of hybrid origin, its parents being H. micrantha and H. sanguinea, is well worth growing, for it is of good constitution and free-flowering, producing graceful spikes of rosy-pink flowers.

H. Zabeliana might well be given a place where a collection of Heucheras is grown, for its wiry stems rise to about three feet, and carry bright flowers of a rosy-pink shade; while H. brizoides, when happy, flowers freely, its blooms being a delightful shade of pink.

There are several other very attractive Heucheras, but the foregoing provide a useful selection. They delight in warm and sunny positions, in good, rich, but not too heavy soil, while they should be divided frequently as, if left undisturbed for a number of years, they are liable to deteriorate. These Heucheras, in a warm season, produce an abundance of seeds, and if these are secured and sown, very interesting and attractive forms may often be obtained.

At one time the Heucheras were popular for furnishing the rock garden, and for such purposes, provided the rock garden is moderately large, they are quite suitable, while they are also very effective when grown in the crevices of heavily-built rock walls.

Finally, mention may be made of the charming little, early-flowering Heuchera tiarelloides, a bi-generic hybrid between Tiarella and Heuchera, with compact tufts of attractive evergreen foliage and erect spikes of rose-pink flowers. It is well worth a place on the rock garden. *M. W.*

VIOLA ARKWRIGHT'S RUBY.

In a most interesting account of Messrs. Clarence Elliott's nursery (*Gard. Chron.*, Vol. LXXXIV, p. 495), a reference occurs to Viola Arkwright's Ruby, and a remark is made to the effect that it is now scarce in nurseries. This is rather surprising, as it is an excellent grower, giving plenty of material for propagation. So far as its beauty is concerned, it is hardly possible to over-praise it. The colour is impossible to describe with accuracy, but the varietal title approaches its hues as nearly as possible. The flowers are large and extremely effective in borders or beds. The plant holds its flowers well upright and, while of the Pansy character of growth, without the tufted habit of the bedding Viola, it withstands the winter well, and in the second year from cuttings provides large plants, crowded with flowers. It was very fine indeed in my garden last year, the most of the plants being from cuttings of the autumn of 1926. Plenty of suitable cuttings are produced, and it is surprising that it is not more plentiful than it is. Arkwright's Ruby appears to do specially well in Scotland, and I saw plenty of it in a nursery last year. *S. Arnott.*

LINARIA TRIORNITHOPHORA.

When well-grown, this Toadflax is an extremely attractive plant, but it is seldom seen in gardens at the present day. A native of Spain and Portugal, it is really a perennial, but in this country is best treated as an annual, as it is very liable to perish during the winter, while it is never very long-lived. If seeds are sown, either in the open ground or under glass during early spring, the resultant plants should be well developed by mid-summer, and during July and August should produce an abundance of the quaint flowers which characterise this plant and which, besides being unique in appearance, are also richly coloured and quite striking.

L. triornithophora is of erect habit, its slender growths, rising to a height of one-and-a-half foot or more, being sparsely furnished with whorls of three or four ovate-lanceolate, acute, light green and glaucous leaves, and terminated by whorls of flowers, three in each, which are short-stalked and quaintly bird-like in appearance, hence the specific name—meaning, bearing three birds. They have long, tapering spurs, broadly inflated at the top, and vary in colour from pale violet to bright, rich purple, the lip being orange.

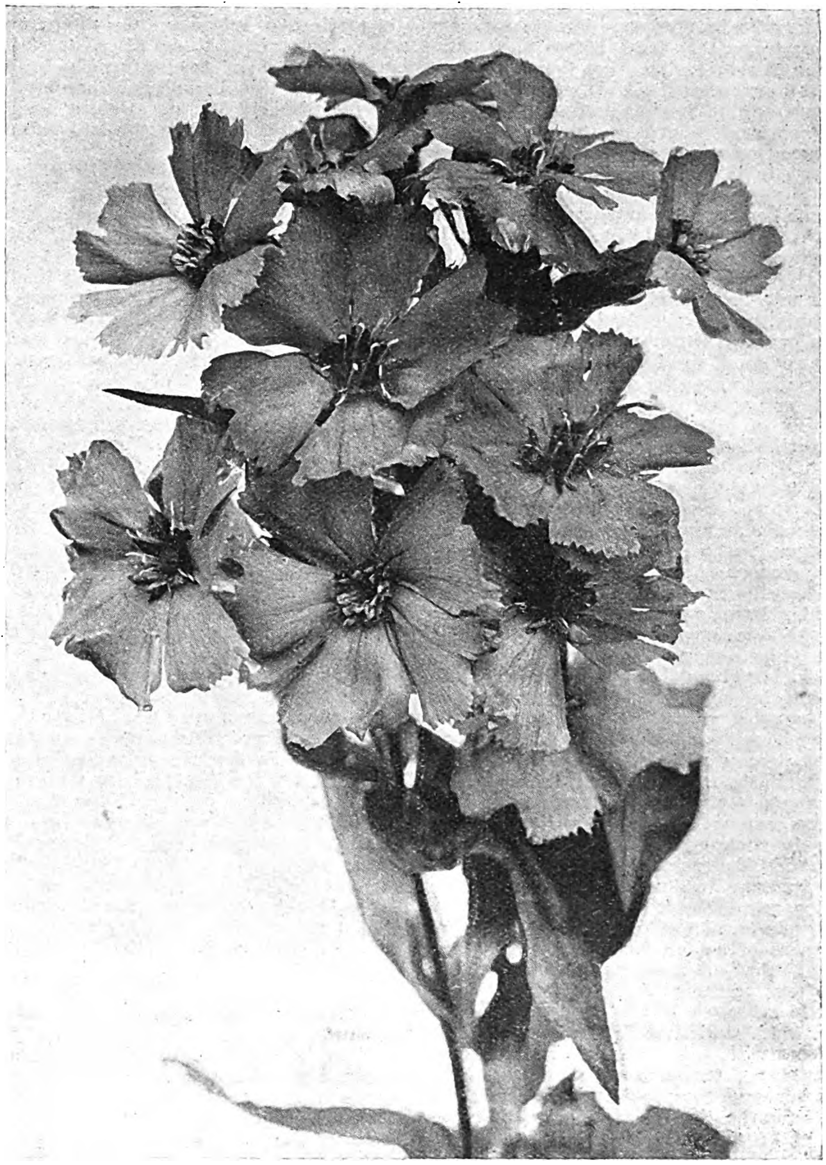

FIG. 60.—LYCHNIS HAAGEANA.

In Farrer's *English Rock Garden* the height of this Linaria is given as four or five inches; this may be true of it in the wild state, but under cultivation this height is usually trebled.

This Toadflax should be grown in a sunny, open position, and in soil which is light and not too rich, for, if grown in rich soil, it will grow luxuriantly, but will not flower with any pretence of freedom; under these latter conditions, indeed, it will present a worthless appearance, a fact responsible, no doubt, for its rareness in gardens. *M.*

LYCHNIS HAAGEANA.

Not many years have elapsed since the beautiful hybrid Lychnis Haageana, whose parents are stated to be L. fulgens and L. coronata, was an extremely popular plant in gardens, but nowadays it is seldom seen, while its many beautiful colour forms are still rarer.

This is to be lamented, as L. Haageana (Fig. 60) is one of the most striking members of its group and invaluable for producing a brilliant and continued display of blooms throughout the summer months. It is tuberous-rooted, hardy and perennial, although it is by no means long-lived, and should be raised periodically from seeds, which it produces freely; its many colour forms, in shades of crimson, scarlet, salmon, pink and white, have been fixed, and may therefore be raised from seeds, the seedlings producing flowers in the second year. The individual blooms of L. Haageana are large and of good substance, being about two inches across, the broadly obovate petals being deeply indented at the apex, and having a long, slender tooth on each side.

L. Haageana is rather particular in its requirements. It dislikes soil of a cold and heavy nature, preferring a light, but moderately rich, loamy medium, and a position not too fully exposed to the sun; in fact, it is advisable to plant the brilliantly-coloured forms in partially shaded positions, as their blossoms have a tendency to fade in colour if fully exposed to the glare of the summer sun. The greatest enemy of L. Haageana is the slug, which, if not watched for and destroyed, will eat the crowns of the tubers during the winter and so render them worthless. *F.*

FLOWER GARDEN.

SALVIAS.

THE genus Salvia contains some useful species and varieties for the embellishment of the flower garden during summer, either as occupants of beds or as groups in the mixed flower border. For the former purpose, varieties of Salvia splendens, with their bright red bracts, are the most sought after. During recent years a decided improvement has taken place in this group, and we now have some excellent forms that come into bloom during early summer and continue in good condition until cut down by frost. But there are still many forms of S. splendens offered which, from the point of view of bedding plants, are very unsatisfactory, as they only begin flowering in late autumn, and are destroyed by frost before they have contributed anything to the floral display. Such forms are more suitable as pot plants for conservatory decoration during the autumn and early winter.

There are also various varieties of S. splendens with so-called violet or purple bracts, but the majority of these are of little or no value for bedding purposes. The same applies to the variety known as S. s. aucubiaefolia, which, as its name denotes, has spotted leaves like those of an Aucuba; the seeds of this form were of Italian origin. It may be a good plant under the sunny skies of Italy, but it is certainly far from attractive when grown here.

To secure good specimens of S. splendens it is advisable to sow the seeds (if seeds are the means of propagation to be employed) in a temperature of 55°, during early February in the north, but in the south, three weeks later should be early enough. When large enough to handle, the seedlings should be potted singly into three-inch pots; pinch the growing points out when about four inches high to induce them to form bushy plants. Repot them into four- or six-inch pots before they become pot-bound, and grow them on as near the glass as possible, later gradually hardening them off in cold frames preparatory to planting. Stocks may be secured that come fairly true from seeds, but a good type is always worth perpetuating by cuttings, which root freely in autumn, or the young growths from stock plants may be secured in spring. These Salvias like a rich, loamy soil, and should be given a position in full sun, where the dazzling scarlet bracts may be seen to full advantage.

Foremost among the many varieties of S. splendens in commerce is Harbinger. This is a moderately dwarf-growing form, flowering with the greatest freedom. Seeds of this form sown last year on March 8, and planted out on June 19, were in bloom by July 16, and continued a mass of colour until cut down by frost in autumn. Fireball is of much the same habit, with, perhaps, rather brighter scarlet bracts, and a little taller.

Early Dwarf Bedder, of Continental origin, is a bushy sort with good spikes, and it is very free-flowering; the time for sowing seeds of this form, and the period of flowering, are the same as in the variety Harbinger. For the purposes of bedding, the three varieties mentioned above will be found reliable.

For bedding purposes few, if any, blue-flowered subjects can compare with the well-known S. patens when well-grown. This native of Mexico has tuberous roots, which should be stored in sand in a frost-proof house during winter, unless grown in districts where the soil in sandy and well-drained; in such places it will withstand the average winter in the open, with the help of a little protecting material, such as dry Bracken, during hard frosts. It is readily increased from seeds, or by cuttings of young growths in spring. From seeds sown on March 8 last year, good flowering plants were obtained by July 16.

Where a dwarf Salvia is required for edging purposes, S. Roemeriana will be found suitable, as this forms a compact little plant from six inches to nine inches high, with bright scarlet flowers.

S. Horminum, which is commonly known as Bluebeard, and is often employed as a bedding plant in northern gardens, is worthy of a place where purple colouring is required, but care should be exercised to secure seeds from a selected stock. S. farinacea is a most attractive species, the tall spikes of violet-blue flowers, borne on wiry stems covered with a white tomentum, imparting to it an elegant appearance. It is a native of Texas, and will come fairly true from seeds if a good stock is procured; there is a white form of it which is seldom grown.

S. fulgens, from the Mexican mountains, is usually regarded as a greenhouse shrub, but it makes a free-flowering bedding plant in the south. The long, bright scarlet flowers are extremely showy and are produced freely, while it will come through a mild winter in the open, producing young growths from the base in the same manner as do hardy Fuchsias. S. involucrata var. Bethellii has whorled spikes of rosy-crimson flowers. Growing from three to four feet high, it is of great value where large beds have to be furnished or for bold groups in the herbaceous border. A wonderful display by this Salvia was noted at Basing Park, Alton, in the late summer of last year.

Another useful species is S. coccinea, one of the brightest-flowered scarlet Salvias, for it produces blooms from June onwards. The corolla is about one inch long, and is deep scarlet, while the flower-spike gives the impression of being of a twiggy nature; the flowers are borne in clusters, a short distance apart, but the flower spikes are produced so freely that there is a constant display of blooms. S. leucantha is another attractive species for the border, for its small white flowers are borne on spikes densely covered with violet-lavender-coloured "wool"; the foliage is silvery underneath and gives a delightful effect. This species is increased easily from cuttings in autumn or spring, but to secure the full effect from this species in the open, it is imperative to have good plants at bedding-out time.

S. argentea is a biennial from the Mediterranean regions, with silvery foliage and pinkish-white flower-spikes which attain a height of from three to four feet. It is useful for planting in bold groups in the herbaceous border. Equally valuable for growing in large borders is S. dichroa, with long racemes of pale blue flowers and coloured bracts.

S. uliginosa is not hardy in every garden but is well worth a little protection during winter. This showy species attains a height of from five to six feet, and from the ends of the leading shoots, panicles, one foot long, of beautiful pale blue flowers are produced. Although tall-growing, it is wiry in growth, and only requires a few twiggy branches around it to provide the necessary support. This species, as well as S. farinacea, provides good material for cutting, the long flower-spikes lasting well in water. *F. W. G.*

ANTIRRHINUMS.

THE wonderful improvements made in these beautiful flowers during the last few years admirably fits them for all kinds of garden and greenhouse decoration. There is now a very extensive range of colours in all the three sections—tall, intermediate and dwarf—and most of the colours are now so well fixed that plants from seeds may safely be used in bedding schemes, both in public and private gardens.

The Antirrhinum is classed as a hardy perennial, but there is no doubt that if the plants are raised during the summer, with the intention of standing through the winter for use the following year, they are better for some protection in the event of severe weather. They are largely used now as annuals, and make a fine display in early autumn, but the best plants result from sowing seeds in the previous year, and wintering the plants in cold frames. These will flower much earlier, and the plants will be finer in every way. For cultivation as annuals, seeds should be sown in early February in well-drained pans, using a fairly light compost passed through a fine sieve. As the seeds are very small, dust the soil surface with silver sand prior to sowing the seeds, which may then be distributed more evenly. Lightly cover the seeds with some sandy soil, and press it down gently, then water them with a fine-rosed can. Place the pans in a temperature of 55° to 60°, and cover them with glass and brown paper to conserve the moisture. The seeds should germinate in a week or so, and so soon as the seedlings are up remove the covering, and place them on a shelf near the roof-glass. When water is required immerse the pans to the rims in tepid water until it has percolated through the soil.

As the seedlings gain strength they should be afforded a slightly cooler atmosphere, admitting air when possible, and so soon as they are large enough to handle, they may be pricked-out into boxes of good soil which has been passed through a quarter-inch-mesh sieve and made fairly firm. Place the young plants about two inches apart each way and water them in as each box is filled. Label each box correctly so that there is no confusion when planting out time arrives. The boxes of seedlings may be placed in a light, airy house with a temperature of about 50°, and water should only be applied when required. If there are plenty of frames at command, beds of good soil may be made up in these, and the young plants pricked out two or three inches apart, giving the surface a dusting of sand before starting. Water them in, and keep the frames closed for a day or two to give them a start. They will soon commence to grow, and air may then be admitted on all favourable occasions. The surface soil should be stirred between the plants occasionally, as this will greatly promote healthy growth. So soon as the plants are strong enough, the lights may be removed altogether in the daytime, so that the plants are fully hardened by planting-out time. This method entails much less labour in watering, etc., and the plants will be sturdier and transplant better. When planting, each plant should be lifted with a trowel with as much soil about the roots as possible, and if the weather is at all dry at the time, the plants should be watered in well.

Although Antirrhinums will grow in almost any soil, they will be much finer if given good treatment in this respect, and the beds or borders should therefore have been prepared well some time in advance. In good soil the flower spikes will be much larger, and the colours more pronounced, and they will also last longer in bloom, than if planted in poor soil. A foot or fifteen inches apart should be a sufficient distance at which to plant them, and they should be put in as firmly as possible. Rake the soil over between them when finished, and afterwards stir the surface with the Dutch hoe. Keep all faded flowers picked off, and the plants should continue to bloom until stopped by frost. The tall varieties will need staking to keep them upright, and when this is neatly done, they are most effective.

Antirrhinums required for early flowering should be sown in boxes or frames early in August, and pricked out into frames as advised for the spring-sown plants. There they may remain all the winter, with an occasional stirring of the surface soil between them to keep it fresh, and a dusting of soot now and then to keep slugs at bay. They should have as much air and light as possible, but should be covered with mats if severe weather prevails. These plants may, of course, be put out much earlier than the spring-sown ones, provided the ground is in suitable condition, and will take no harm from ordinary spring frosts.

The best varieties are also very useful for growing in pots, especially the variety Nelrose a beautiful, silvery-pink variety, and a strong grower. Seeds should be sown about mid-summer, the seedlings being potted on as occasion demands; if dwarf plants are required, they should be pinched back once before the winter arrives. They may be grown on into five-inch pots, wintered in a cool frame, and repotted into seven-inch pots early in the New Year, giving them a good, fairly rough compost of two parts rough turf, one part leaf-soil, and one part old, well-decayed manure, with a little coarse sand added. Grow them under quite cool conditions as the season advances, and if they have been allowed to grow naturally they will require staking, as they will reach a height of four or five feet if well grown.

To obtain fine flower spikes of Antirrhinums for exhibition, the plants should be thinned to three or four shoots, or even fewer, with some varieties and they should be mulched with decayed manure and well watered if the weather proves dry. Some of the more delicately coloured varieties will require shading from very hot sunshine, while the spikes should be staked if there is danger of them being broken by wind. I forbear to mention any varieties for outdoor culture, as the perusal of any good seedsman's list will furnish all the knowledge required. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

PLANTS NEW OR NOTEWORTHY.

ASTILBE KOREANA.

The genus Astilbe consists of about fourteen species, and these are scattered over the more temperate parts of China, Japan and India. The fine species under notice was found by Mr. E. H. Wilson when plant-collecting in Korea, and has been in cultivation here for a good many years, but for some reason has never become common.

I cannot remember ever seeing this plant exhibited in London. Astilbes are frequently shown, but are more often the many fine hybrid forms that Continental plantsmen have been so successful in raising. These hybrids, are, in fact, more showy, of richer colouring and greater vigour than some of the species. The influence of A. Davidii, which was also one of Wilson's many good finds when collecting in China for Messrs. James Veitch and Sons, is seen in these Continental varieties.

A. koreana is always a striking feature about late August or early September at the Edinburgh Botanic Gardens. Indeed, it is more often seen in Scotch gardens than in those of the south. The plant is of tall, stately habit, with immense plumes of white flowers which are sometimes tinged with pink. Seeds of this first-class border plant are now available—probably for the first time—and are offered by Messrs. Dobbie and Co., of Edinburgh. *T. Hay, Hyde Park.*

THE PASSION FLOWER.

Although Passiflora caerulea is not absolutely hardy, this South American climber will survive most winters if grown against a warm, south wall, especially if the rootstock is in a sheltered corner. Even if a considerable portion of the plant is killed by frost, its recovery on the advent of warm weather is so rapid that the new, strong growths soon cover the vacant space with handsome foliage. In favourable localities, flowering commences in July and continues until October.

Although not a showy climber, the flowers are curiously beautiful, and repay a close examination. The calyx and petals are of similar size, greenish white on the outside and tinted with blue and purple inside. The greatest attraction in the flowers lies in the rays of the so-called "corona," composed of peculiarly fine, thread-like growths, radiating from the centre, their colouring being a rich harmony of blue and purple contrasted with white; through this coronna rises a bold, purplish style.

Half-hardy climbers are usually sold in small pots, and it is a great advantage to purchase early, and pot them into pots of a larger size, to obtain a vigorous, healthy root-system, capable of promoting rapid growth; plant early in April. The Passion Flower will grow in any ordinary soil, but good drainage is a necessity. It does not cling naturally to the wall like Ivy, but is supported by its numerous tendrils, and a trellis or wires must be provided on which to train it. Pruning should be done in March, removing all dead wood, and thinning out the weaker growths.

Plants in this garden often produce yellow, egg-shaped fruits containing fertile seeds, from which plants have been raised, but the easiest method of increase is by means of short, axillary growths which root quickly in a warm frame, partially filled with sand.

Passiflora c. var. Constance Elliott is a white variety raised by Messrs. Lucombe Pince and Co., of Exeter, in 1884. It was very common as a greenhouse plant for a few years, but it has never attained the popularity of the older plant.

For many years we grew a purple variety and much doubt was expressed by several authorities as to its identification. Some time afterwards, the late Mr. W. Watson wrote to say that he believed it originated with Messrs. H. Cannell and Sons, and was named by them Eynsford Gem. Like many other good plants, it was lost during the war; should any reader possess a plant, I should be pleased to hear from him. Nicholson's *Dictionary of Gardening* lists three probable hybrids of P. caerulea, viz., P. c. Colvillei, P. c. kermesina and P. c. racemosa. Are these still in existence? *J. Comber, Nymans Gardens, Handcross.*

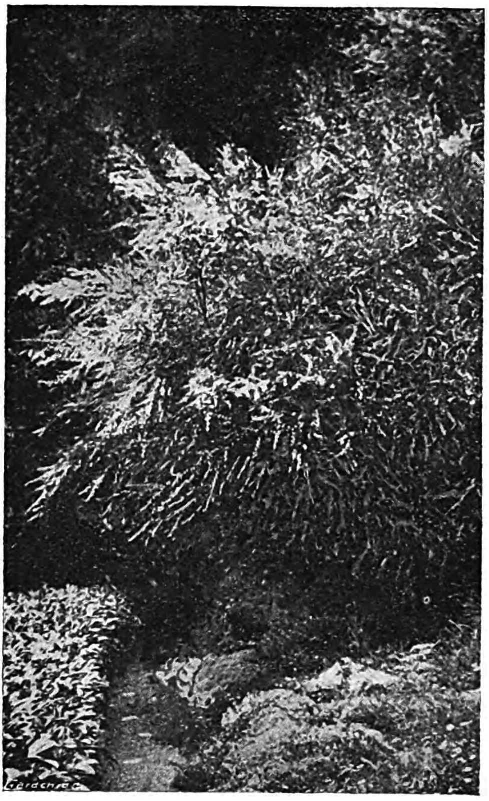

FIG. 61.—LEPTOSPERMUM SCOPARIUM AT AVOCA, CO. WICKLOW.

TREES AND SHRUBS.

SALIX DAPHNOIDES.

A native of central Europe, eastern France, Russia, Italy and Asia, this beautiful Willow is not planted so often as it deserves to be, for there are few kinds that can surpass it for beauty of flower or bark. Planted by the water-side, this shrub will attain a height of forty feet, and is an admirable subject for preserving intact the verge of a lake. It is one of the most attractive Willows in autumn and throughout the winter months, for the silky hairs protruding from the buds form a pleasing contrast with the purplish colour of the twigs and branches. The male is the most desirable form, producing its very large catkins on "bloom"-covered, somewhat viscous twigs in February or early March, long before the narrow, acuminate leaves make their appearance.

S. daphnoides var. acutifolia is similar to the type, but has narrower and more gradually acuminate leaves. S. daphnoides var. praecox has reddish-brown twigs, and is the earliest Willow to flower in this country, the male form producing its catkins, with large, golden-yellow anthers, usually about a week before the type.

The colouring of the bark being most vivid on the young growths, to obtain dwarf plants with long annual growths these Willows should be pruned so soon as the anthers have shed their pollen. Propagation is of the easiest, quite large branches rooting readily at this time of the year. *J. Blades, University Botanic Garden, Cambridge.*

LEPTOSPERMUM SCOPARIUM.

Leptospermum scoparium, the Ti Tree, which forms much of the scrub of New Zealand, and Australia, is a very beautiful evergreen shrub, with very small leaves and long, graceful sprays that are thickly studded with white flowers in June, the individual blooms being of the shape and size of small Strawberry flowers. In any fairly mild climate, given a sunny, sheltered position, in rather poor, light, well-drained soil, it will flourish and attain a height of eight feet to ten feet. It is increased easily by seeds, and the young plants begin to flower when about three years old. There are several very charming varieties of this shrub with blossoms of different shades of crimson and scarlet.

The accompanying illustration (Fig. 61) shows Leptospermum scoparium as it flowers every summer in my garden. *W. F. Wynne, Avoca, Co. Wicklow.*

VACCINIUM OVATUM.

A very handsome shrub from western North America, and quite capable of withstanding our severest winters, although the young growths may be slightly cut during severe frosts, Vaccinium ovatum forms an erect, evergreen bush, up to ten feet high, in this country. The young wood is purplish and rather downy, and the foliage takes on gorgeous autumn colouring in favoured situations. The leaves are about an inch long and half as wide, rounded or tapering, minutely toothed, of a very firm and leathery texture, and glossy green above and below. The flowers are produced in the autumn, six or more together in short, nodding racemes, in the leaf axils; they are fairly inconspicuous, and are followed by handsome fruits, which have an agreeable flavour when ripe, which is seldom in this country; they are glossy black and about one-third-of-an-inch in diameter.

V. ovatum was discovered by Menzies, and introduced by Douglas in 1826; there are very fine specimens of it growing in Lord Clinton's garden at Bicton, in Devonshire. *Will Ingwersen.*

LEUCOTHOË DAVISIAE.

Among the various shrubs to which the generic name of Andromeda still clings this is one of the most attractive. It is a native of the higher altitudes of the Californian Sierra Nevada, and was discovered by William Lobb, who introduced it for Messrs. Veitch in 1853. L. Davisiae is an evergreen shrub of dwarf, compact habit, averaging about two feet in height. The ovate-oblong leaves are rounded at the base, bluntly pointed, some two inches long, and half as much in width. This foliage is a rich, glossy green, and makes a telling setting for the pure white flowers. These latter appear about midsummer in clusters of racemes which rise from the tips of the shoots and terminal leaf axils. Each raceme being nearly four inches in length and the individual pitcher-shaped blooms one-quarter-of-an-inch long, a specimen of L. Davisiae in flower is singularly beautiful. Moreover, the tufty inflorescences well illustrated in Mr. W. J. Bean's *Trees and Shrubs Hardy in the British Isles,* show to full advantage since they rise well above the foliage.

L. Davisiae appears to be quite hardy, and it does very well with me in a light, woodland loam with partial shade. The latter is probably not essential where there is sufficient moisture, and if I remember aright, the good specimens of this species at Wisley get most of the sun. Propagation may be carried out by means of cuttings in August, but as L. Davisiae spreads by suckering it is often possible to secure rooted off-sets without disturbing the main plant. *N. Wales.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER ; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XIII.—The First Climb.

The trees mentioned in the last chapter were not the only ones identified in the Lohit valley. Altingia excelsa, a giant of a tree, was fairly common, and was found some distance up the Delei. It is deciduous, and is easily recognised by its globular, wooden heads of fruits, many of which remain long on the tree. Another massive species, to which attention was first drawn by its fallen branches, laden with fruits, was Cedrela Toona, but this was rather rare. Much more common than either of the above was a species of Talauma (T. Hodgsoni probably), an evergreen tree, bulky, but of no commanding height. I wanted to see this flower, but we departed before the big buds burst. Albizzia Julibrissin was flowering on boulder banks in the river bed, a form with pale yellow corollas, very slightly longer than the calyx, white stamens, and leaves softly pubescent beneath. It is one of the first trees to establish itself in such barren situations, and with it on the pebble bank, amid a wilderness of rank grass, were bushes of Elaeagnus, and several Leguminous shrubs. Higher up the Delei valley, Albizzia Julibrissin was much commoner, especially in villages where, if not actually planted among the crops as a shade tree, it was certainly preserved; but in the warmer and wetter climate of the Lohit, A. procera, not yet in flower, was more at home. Another Leguminous tree noticed was Pithecolobium bigeminum, which I found in bloom on April 3; indeed, woody Leguminosae, trees, shrubs and climbing plants, were abundant and varied, forming a feature of the forest vegetation; an Acacia flowered before we left, and a climbing Bauhinia did not.

Apart from trees and shrubs, the poverty of flowers was noticeable, herbaceous plants getting a poor show in any Indo-Malayan jungle. There were a certain number of Orchids, mostly epiphytic, but few of them were in flower.

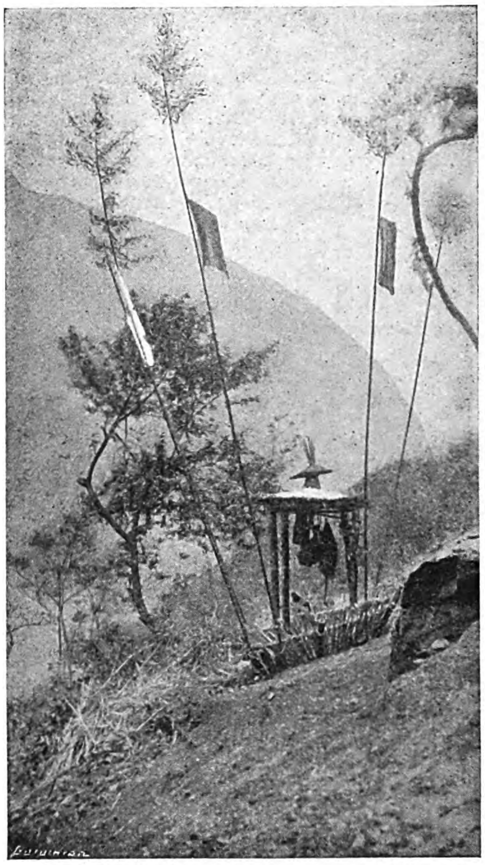

FIG. 62.—A SHRINE IN THE DELEI VALLEY, MISHMI HILLS.

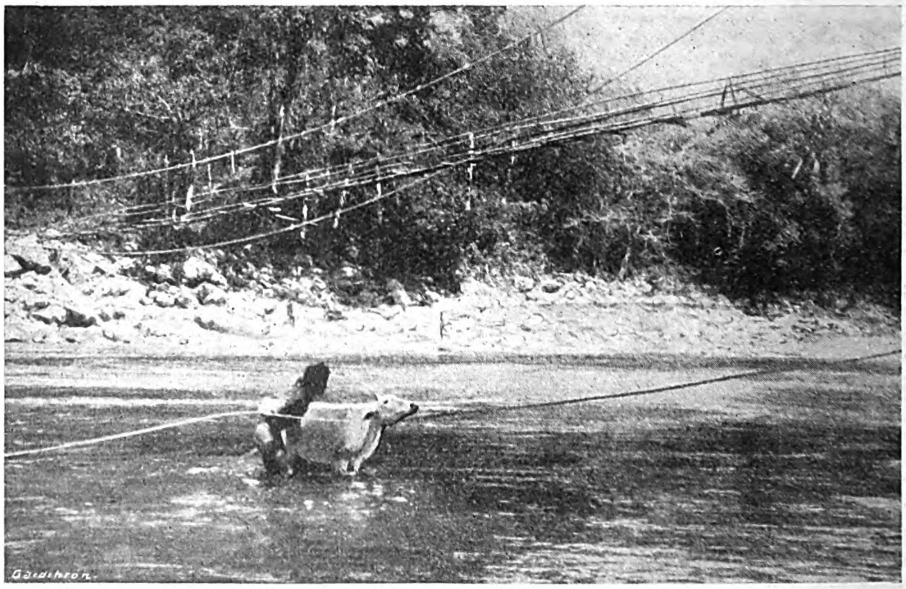

FIG. 63.—MISHMI SWIMMING CATTLE ACROSS THE DELEI RIVER, UNDER ABANDONED BRIDGE.

Besides these, there were in the forest, Begonia, Impatiens and Arisaema; in cultivated places, Violets, Cynoglossum, Polygala, and various small Compositae and Acanthaceae; in open pastures, Solanum; and on wet rocks, the big, violet Chirita, which is a showy plant. But the most gorgeous tropical flower was a species of Aeschynanthus, which instead of having solitary, pert flowers looking out from the paired leaf-axils, flaunted them in balls of audacious scarlet, looking like nothing so much as a blood-red Rhododendron arboreum which had taken to the tree tops. As a matter of fact the plant hung down, a glowing streamer from above, and I rubbed my eyes at first sight of it, wondering whether I had at last really caught that will-o'-the-wisp, a climbing Rhododendron !

After Leguminosae, perhaps the most conspicuous objects in the forest, and certainly the most varied, were the Araliaceae. Commonest of all was the climbing Heptapleurum venulosum, which usually perches itself in the fork of a low tree and develops into a big, slumbering, smothersome bush, although maintaining contact with the ground. This was in flower. Another species flaunted large bunches of small, bright yellow berries, which were rather striking. Then there was Tupidanthus calyptratus, two specimens of which had enveloped as many huge boulders which overhung the river bank, while a third specimen formed an immense climber with a stem as thick as a man's thigh. Heteropanax fragrans and Trevesia palmata have already been mentioned, and one or more species of Brassiopsis were common.

In thickets and secondary growth generally, there were sure to be various Urticaceae and species of Solanum. Among the last-named were S. verbascifolium, a small tree with flannelly leaves and white flowers; S. Kurzii, a thorny shrub with violet flowers, and the herbaceous S. torvum. A fourth species was notable for its wealth of bright orange berries—a small, unarmed, glabrous bush.

Mention must also be made of several Skimmia-like Rutaceae, all of them in fruit. One, which was probably Skimmia Laureola, had scarlet berries, a second, about the same size, had carmine berries, while a third, which often grew to the height of a small tree, albeit a slim one, bore large bunches of purple-black fruits like Cherries. All three formed part of the forest undergrowth. So much for the valley flora; nor was there much difference between the jungle here and on the Sadiya plain. But, as I have stated, we were surrounded by high hills—from certain vantage points, indeed, we could see peaks both up and down the valley, 12,000 feet high or more, and snow-clad. Day after day we had looked up the Delei valley to where a rock-rib curved down from the mountain backbone, shutting out the view beyond, and seen that its sky line was fringed with Conifer forest; or across the Lohit, and lifting our eyes straight up to the 9,000 feet crest, directly opposite us, after the passage of a brisk thunder storm, had observed the ragged file of trees powdered with fresh snow. It might therefore be possible, by an effort, to

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV January 19 and February 2, 1929.

reach a rarer atmosphere, even from our present base line. In the angle between the two rivers, the mountain ridge rose sharply to an altitude of 6,000 feet, directly above our camp; and as early as March 19 we set out to climb the 4,000 feet to the summit.

After toiling up through the forest for a thousand feet, we came out into cultivation on the ridge, where the slope eased off, and it proved an exhausting pull up in the hot sunshine. Cultivation extended intermittently all the way, being carried to 6,000 feet, wherever the face is not too precipitous; but the soil looked hungry, what there was of it, and it was choked with boulders. We passed a solitary hut, with a Peach tree enveloped in a cloud of pink blossom. The path was quite good, as this is the main route into the upper Dou valley, a river which flows into the Lohit just beyond the Delei; and from the summit we saw the snow peaks at the head of the Delei on the one hand, and at the head of the Dou on the other, the whole horse-shoe range blocking the view northwards into Tibet.

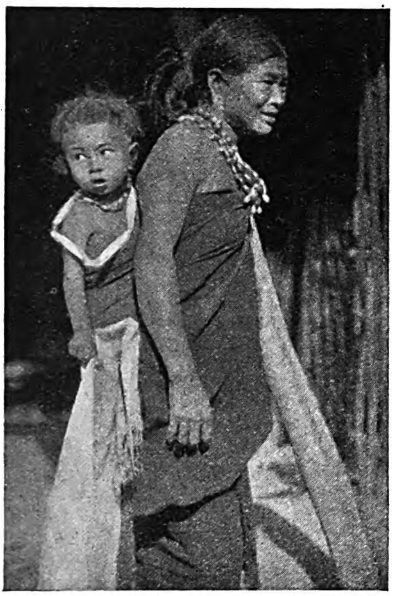

FIG. 64.—HOW BABIES ARE CARRIED IN ASSAM.

Not until we reached the top of the dividing range at 6,000 feet did we find any shadow of a temperate flora. It was now three o'clock. I had time to go a short distance along the ridge, and suddenly I found myself on the fringe of the temperate forest. Here Rhododendron arboreum was just coming freely into flower, and beside it was a 'Stamineum' Rhododendron, with a crop of last year's capsules from which I rescued a few seeds. Other Ericaceae included species of Pieris and Gaultheria, and I also noticed an evergreen Ilex whose breaking leaf-buds covered the bush with amethyst plumes. This loot at least served to whet the appetite, and we got back to camp at dusk after a successful excursion.

We had great difficulty in buying any food locally, and our interpreter, Hubble-Bubble by name (or something like that) spent most of his time going from one remote hut to another trying to procure a fowl or a few eggs. Occasionally he was successful. We also got some small, but quite good Bananas, and a few Sweet Potatos. For the rest we had to supplement our rations of Rice and flour with precious stores.

March 22 was our first really wet day for a fortnight. The 27th was also wet, and the 30th and 31st and April 1. This succession of rainy days, which had effectually stopped all further transport up the Delei, was brought to a close on April 2 with a round of thunder storms, the culminating set-piece going off with a fine bang in the middle of the night. When we woke up on the 3rd to see the sun shining again, the great spur which framed the Delei, and the peak just across the Lohit, were delicately powdered with fresh snow.

During the second half of March, the minimum temperature, at 2,000 feet, averaged about 54° — lowest 49° on the 19th, highest 56·5° on the 16th. On fine mornings there was heavy dew. On wet, sunless days the temperature rose little above 60°, but on fine days it went over 80°, and it was 87° in my tent on April 3.

Bands of Mishmis were still passing by our camp every day. Many of them drove cattle which they had bought on the plains, and as these creatures could not cross the wreck of the Delei bridge, they had to be towed across the river by means of a Bamboo line round the neck (Fig. 63). Swim they could not, although sometimes they made stout efforts; and a frequent result of hauling too hard athwart the fast current was that the miserable animal turned turtle and was pulled ashore in a state of apparent insensibility; although the rapidity of their recovery, when they were pushed right side up and found solid rock beneath them once more, suggested mere bovine resignation.

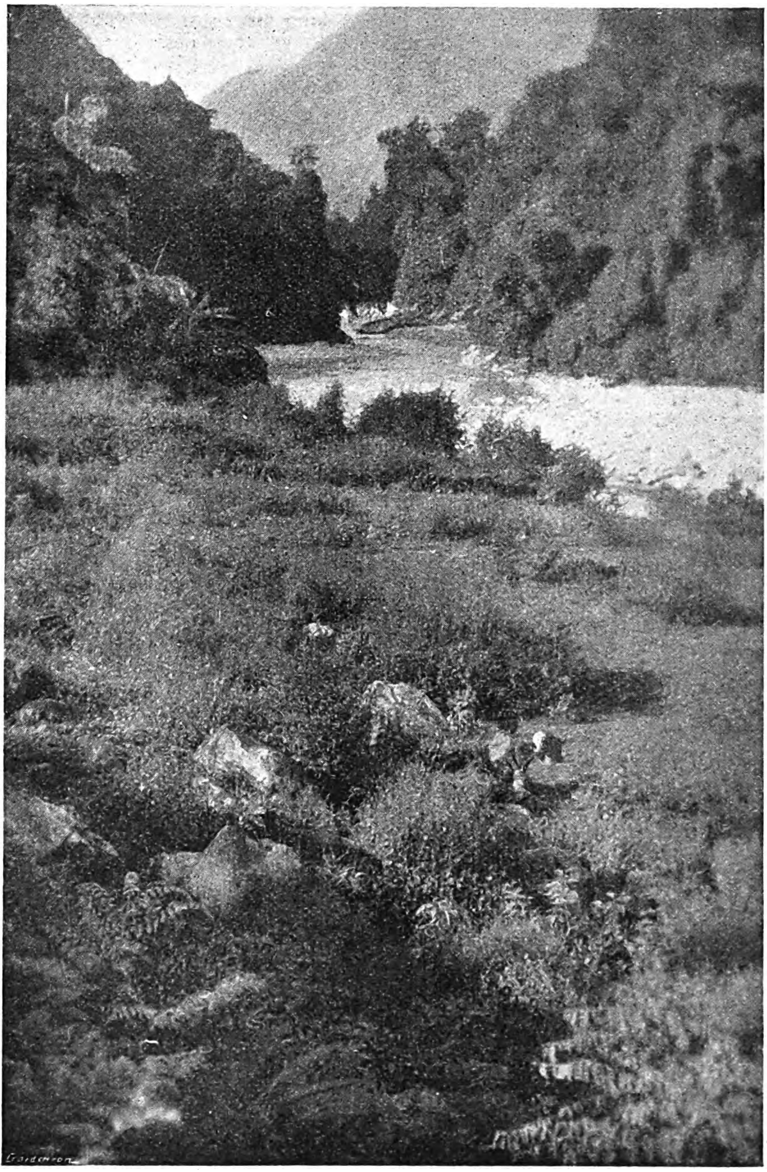

FIG. 65.—THE TIDDING VALLEY, FROM THERONLIANG, THE LAST BUNGALOW IN ADMINISTERED TERRITORY.

After the close of the last rainy session, four coolies arrived to carry loads. By this time we were much exercised to decide what we could do without, being already stripped down to a light camp. The Quartermaster in particular was embarrassed, as he had sent on practically all rations and stores, thinking every day that we should be able to follow them; yet day after day passed, and we were still here, and getting near the end of our tether.

What we wanted, of course, and wanted very badly, was a posse of coolies to move us *holus bolus*; yet we could not afford to send four away empty, and eventually we made up loads for them, still further skinning the camp. When, however, only three coolies arrived next day, I realised that we must go in two detachments. More coolies were promised in the near future, so leaving my companion to follow so soon as possible, I started up the Delei valley on April 4, accompanied by three coolies and the interpreter, with my bedding, botanical presses, and a little food. By this means we reduced the pressure on the food which remained, and, arrived at the forward dump, I could send back ample supplies and, perhaps, coolies, to the rearguard, which would join me at the earliest opportunity. *F. Kingdon Ward.*

PLANT HISTORY IN NOMENCLATURE.

(*Continued from p.* 82).

ORANGES AND LEMONS.

It was only natural in the days when philology was a matter of popular etymology that the name of the delicious golden fruit which we call the Orange should be thought to come from the Latin word for gold. What could be more appropriate ? This false idea is responsible for some of the forms which the name has assumed in its passage from the original Persian through the French and Spanish to the English.

" ORANGE, *aurantio*, Italian : *aurantium*, L., meaning : of *aurea colore*, the colour of gold," state the good old dictionaries of two centuries ago. What could the Golden Apples of the Hesperides be, if they were not Oranges ? As the form of the word has been affected by its long pilgrimage, we naturally turn to the Romance languages for light, and thus learn that in Portuguese an Orange is termed *laranja*, while in Spanish it is *naranga*. In speech the initial letters *l* and *n* are frequently confused, so we may assume these two forms represent the same word. The initial, however, is wanting in the Italian *arancio*, and in the French *orange*, although retained in the Modern Greek *nerantzia* or *narantzia*. Skeat tells us that in French, Orange was formerly spelt *orenge*, and that this stood for *narenge*. In Italian the initial was lost and then *arenge* became *orenge* by popular etymology from *or*, meaning gold. Brachet confirms this. " The French word (he writes) ought to be narange (like the Spanish naranja), but has taken its present form, Orange, from a confusion with the word *or*. In Latin the Orange was called aureum malum (or the golden Apple), and the French consequently thought to find the sense of golden in the word it adopted."

We next have to enquire into the earlier history of the word. If it is not of Latin origin, and has nothing to do with gold, whence did it come, and what did it mean ? Pushing our enquiries back, we find that commerce with the East led the French, Spanish and Portuguese into intimate relations with the Arabs and other Semitic peoples. The Arabs spoke of the Orange as *narandj*, a word which is also found in Persian, and written *naranj*, *narinj*, or *narang*. Comparing the Spanish, Portuguese and Modern Greek with these, we conclude they must be one and the same. Further, in Persian, the Pomegranate is called *nar*, and it would thus appear that the word Orange, or Narange, is intended to suggest a fruit similar to the Pomegranate.

It might be objected that we have no right to assume that the Italian has lost its initial letter, and therefore that we cannot connect *arancio* with *naranj* ; and as such criticism is fair, it must be fairly met. Fortunately, this is easy, and if we enumerate the names for Orange in a number of different dialects and languages, we shall not only find that the initial may be lost, but that if it is retained it is liable to other changes than those already specified. Forms beginning as in the Persian and Arabic are the Milanese *naranz*, Venetian *naranza*, Spanish *naranja*, Wallachian *neranze* and Modern Greek *nerantzi*. Forms with other initials include the Portuguese *laranja*, and Basque *larania*, as well as the curious Catalonian *taronja* and Turkish *turunj*.

In former days no etymology was considered perfect if it could not be traced back to Sanskrit, and it was therefore natural that philologists should try to discover in that language the original of our Orange. One distinguished writer informs us that there was a Sanskrit name for the Orange, and this was written *nagarunga*, or *nagrunga*, and that the Hindûs corrupted this into *narungee*, or *nerunga*, whence the Arabic or Persian *narunj*, the Italian *naranzi*, mediaeval Latin *arancium* and *aurantium*, and the French and English " Orange." Other students, however, have failed to trace the name to the Sanskrit. *Naga* means a serpent, and the term is applied to those fabulous serpents which have a human face. It is therefore easy to imagine how legends regarding serpents in gardens, such as Eden and the Hesperides arose, and how these came to be associated with the Golden Apples. It would not be difficult to imagine that the ancients named the Orange the fruit or tree beloved of the Nagas, but, unfortunately, history and legend alike fail us here. How the Orange is associated with the garden of the Hesperides, however, may be found in that wonderful repertory of plant-lore by Professor Angelo de Gubernatis, entitled *La Mythologie des Plantes*.

This leads us to remark on the curious fact that in Turkey and elsewhere, Oranges are known as Portagals or Portogalotti, about which the same writer gives us much interesting information. If now we enquire into the original home of the Orange we encounter a problem which forces us to consider the names for the fruit to be found in other lands. If the Sweet Orange had been cultivated at a very early date in India, it would, as A. de Candolle remarked, have had a special name in Sanskrit, but it has not. If, however, we turn to China, we find a very instructive series of names. De Candolle stated that we come back by all sorts of ways to the idea that the sweet variety of the Orange came from China and Cochin China, and that it spread into India, perhaps, towards the beginning of the Christian Era. Now the Chinese have several native names for the Orange, and some of these are of such antiquity as to find a place in the oldest dictionaries and classical writings. One of these terms, *kat*, *kwat* or *quat*, is more or less familiar to Europeans in the name Cumquat, or Golden Orange (*Citrus madurensis*), found in south China. Osbeck alluded to it in 1751 as " Kammkatt—the name of a sort of small Lemons, which are not much larger than Cherries." He stated elsewhere of the same plant that it is " a sort of low sweet Orange tree with a small fruit which is called *Gatt* in Canton." Another word for Orange which is very ancient is *kom*, also pronounced *kan*, or *kang*, as in Foochow. This is very ancient, and the picture word is composed of a tree and the symbol for sweet or pleasant, showing that ages ago the Orange was regarded as a great delicacy or as a fruit to be desired. A further native word is *Ch'áng*, and this is used when speaking of Orange wine (*ch'áng tsaû*), Sweet Oranges, and Candied Oranges ; all of which makes it clear that this favourite fruit has long been known to the Chinese.

The Linnean Society's *Flora of China* contains descriptions of some half-a-dozen different species of Citrus from China, and remarks that while the herbarium specimens appear to be all of cultivated origin, there is little doubt that some, if not all, are really native in one part of the country or another. *Hilderic Friend.*

(*To be continued.*)

HEMEROCALLIS.

Mr. B. Y. Morrison's excellent and exhaustive paper on the Yellow Day Lilies (see pp. 50, 65, and 84) received a hearty welcome by English lovers of the genus. When one finds that the Royal Horticultural Society is holding a trial of Hemerocallis at Wisley, and that Mr. Amos Perry's catalogue offers a choice of thirty-nine kinds, I am tempted to think that these charming flowers must at last be gaining a little popularity. I can but wonder that they have not gained it before, for they possess, in most of their forms, bright colouring, fine foliage, pleasant fragrance, and sufficient good nature to accommodate themselves to almost any position in the garden.

I have known and zealously studied the plant for over forty years, and there can be no doubt that in size and shape of flower, to say nothing of colouring, much has been done to awaken interest. I should like, here, to express my warm thanks to my friend Mr. Amos Perry for all that he has done for the Hemerocallis, as well as for his kindness to myself personally, and add that Mr. C. H. Curtis, of *The Gardeners' Chronicle*, was one of the first—in the days of long ago, at York—to offer encouragement in my earliest efforts to improve this genus.

The species known in gardens as H. flava, H. minor, H. fulva (Kwanso), H. Middendorfii, H. Dumortieri (syns. Sieboldii and rutilans) and H. citrina, do not require description ; Mr. Morrison has already described them and indicated the countries from which they originally came. Of H. aurantiaca and H. aurantiaca major, I shall write later ; of these, Mr. Morrison also treats.

To this list has lately been added a dwarf kind named H. nana ; it is of a pleasing orange colour, with a reddish-brown back, and seems likely to be of considerable value to the hybridist. I have grown it for several years, having obtained it from Wisley, thanks to the kindness of Mr. F. J. Chittenden. I have, during the summer of 1928, flowered some of its seedlings. I believe I made the cross both ways between H. flava and H. nana ; at any rate, some of the seedlings are twice as tall as others and may probably have H. flava as mother, while the dwarfer ones may claim the maternity of H. nana.

I learn from Mr. Perry of another new species, named H. plicata, of which he has a high opinion. Thanks to Sir Arthur Hort, I have three kinds which he obtained from the late Mr. H. J. Elwes under the names of H. urmiensis, H. hippeastrioides, and H. Sippan. They flowered with me in 1928, and were quite pretty, although of no special distinction. One other plant, named H. nucerensis, which I possess through the kindness of Mr. R. W. Wallace, of Tunbridge Wells ; although it should, by its name, be a species, I suspect it to be a hybrid of H. citrina. Its name suggests Nocera, near Naples, as its birthplace. It is a fine thing.

Perhaps I may be excused for dipping a little into ancient history in telling the story of how the sight of an established plant of Hemerocallis Middendorfii, in fine flower, by the side of the main walk down the York Nurseries, suggested to me the cross H. flava and H. Middendorfii, which produced H. Apricot ; and H. minor × H. Middendorfii, which gave me H. Frances. Preparatory to my crossing campaign, I obtained twenty-five H. flava and twenty-five H. minor—extra good plants—from Messrs. Fisher, Son and Sibray, of Sheffield. The railway man, who delivered them on a Saturday, surprised me by saying—he must have been a gardener—" I thought you would like to get these plants into the ground so soon as possible." The ground had been prepared for them in haste. I had asked the man who took the waste from the kitchen for his pigs to bring me a little manure. Imagine my horror when, on returning from school, I saw a great heap of raw pig manure ! Never did ordure make its presence known more vehemently. So fear of a visit from the Inspector of Nuisances caused the dreadful mass to be dug in with all speed. Thus I gained a fine stock of these two kinds ; H. flava flourished, but H. minor gradually died out.

Then I obtained H. Dumortieri (syns. Sieboldii and rutilans). The pollen of this variety on H. flava was effective, and resulted in many seedlings, which varied considerably. The tallest, H. Estmere, was quite a good plant ; so was the widely-expanded H. Sovereign, which I originally called H. Beauty. I ought, perhaps, to explain that the names H. Sovereign, H. Gold Dust and H. Orangeman were not given by me, although I was, I believe, the first to make the cross. One of the best seedlings I named H. William Dean, in remembrance of that well-known horticulturist who had visited my garden, and, if I remember rightly, wrote an account of it in this journal. I also, about this time, had a visit from Mr. Amos Perry (senior), whose acquaintance I had made at the Tottenham nurseries, when he was manager there for Mr. Thomas Ware. He had there delighted me by the way in which he got rid of a troublesome but self-satisfied ignoramus who, after talking to Mr. Perry some little time, said, decisively, "And now I want someone who really knows all about them to take me round the Narcissi." Mr. Perry thereupon called a young gardener who was at work close by and said : " Show this gentleman round the Daffodils." Thus, for once, poetical justice was done.

Like other growers, I failed completely to raise seeds from H. fulva. I may state that, in my holiday travels, I carefully examined all the plants of H. fulva that I came across in Switzerland, Auvergne, Italy, Sicily, the Lipari Islands, the Black Sea coast of Asia Minor, and the Caucasus, but I never saw a seed-pod. Eventually, Herr C. Sprenger, of Vomero, Naples, succeeded in crossing H. fulva maculata with H. aurantiaca. But alas! when H. fulva maculata, obtained with much trouble, to my great satisfaction flowered at York, it refused to seed.

When H. aurantiaca major first appeared in catalogues, I bought a plant of it for half-a-guinea. The first year it did not flower; the second year it bloomed in October, too late to be of use. The third year, when I was serving on a deputation from the R.H.S. to the Newcastle-on-Tyne show, Mr. R. W. Wallace exhibited it in flower, so I got him to send me two buds, which opened in water, and, having previously prepared many flowers of H. flava in the garden, I crossed them with its pollen, and thus acquired H. Corona, which has a large and stately bloom.

H. aurantiaca I obtained at a later date, and found it very good-natured. (There was at one time a fine bed of it in the York Nurseries). My best seedling from it and H. flava was named H. Miranda. It failed to gain the Award of Merit, but is, to my mind, one of the best of the tall varieties. I prefer it to H. Corona. The foliage, at any rate in its raiser's judgment, is more graceful than that of any other Day Lily.

H. Thunbergii for several years refused to seed with me, and then suddenly produced seeds in abundance. H. Thunbergii × H. Middendorfii gave a disappointing flower, but I have found it useful as a parent. H. Radiant, although I cannot recall the actual cross, has evidently H. Thunbergii blood in it.

Of H. Tangerine, an early dwarf, very effective in the mass, I have lost the parentage. More striking in colour than any H. Dumortieri, I have yet come across is the seedling named H. Flame, when well established. It may here be observed that all Day Lilies, to appear at their best, must be well established.

The following have gained the Award of Merit (or First Class Certificate) of the Royal Horticultural Society:—

Species.—H. disticha plena, 1860; H. Kwanso plena variegata, 1886, F.C.C.; H. Middendorfii, 1887 (Dr. Regel, A.M., 1905, is a late-flowering form of H. Middendorfii); H. aurantiaca major, 1895, F.C.C.

Hybrids.—Apricot (Yeld), 1893; Frances (Yeld), 1894; Corona (Yeld), 1905; Luteola, (Wallace), 1905; Golden Bell (Wallace), 1915; Lady Fermoy Hesketh (Perry), 1924 (Fig. 35, p. 65); Winsome (Yeld), 1925; Radiant (Yeld), 1925 (the first to obtain an Award of Merit at the Wisley Trial); Margaret Perry (Perry), 1926; and J. S. Gayner (Yeld), 1928 (recommended for trial at Wisley).

Here should also be mentioned my namesake, H. George Yeld, one of Mr. Perry's best flowers; and H. Hyperion, raised by Mr. Franklin B. Mead, of Iriscrest, Fort Wayne, Indiana, who is greatly interested in Day Lilies and grows fifty-eight varieties in his famous garden. Mr. Mead thus describes H. Hyperion: "Hyperion, a cross between H. Sir Michael Foster and H. Florham, is a new seedling raised at Iriscrest, and appears to be the very finest of its genus. It surpasses all other Hemerocallis in size, form, colour and substance, and is equalled or surpassed in texture only by the rare and beautiful Japanese hybrid Royal. The flowers of Hyperion, on stout stems forty-two inches tall, are from five to six inches across, and are of the purest canary-yellow; in comparison, H. flava appears to have some orange in it. Hyperion is one of the most imposing of all perennial plants." Thanks to Mr. Mead's kindness, I hope to flower it in my garden next summer. Mr. Mead informs me that he has sent plants to the Wisley Trial which is now proceeding. *G. Yeld, Orleton, Gerrards Cross.*

THE TREASURE BOX.

Thus have I christened a small piece of rockery which I built some five or six months ago for the accommodation of various rare, curious and otherwise noteworthy plants from the general collection. Where a great many plants are grown together, it is almost unavoidable that a few odds and ends here and there should be overlooked, and it is often these very odds and ends which constitute the most interesting part of the collection so, as stated, this small rockery was built that odds and ends might be planted thereon and increase mightily, which the majority have certainly done.

With the construction of it we need not greatly concern ourselves, sufficient to say that it is built in what I call the "pudding" style, namely, an outcrop jutting from the bare ground, with no great pretension to ornamental design, but intended just as a suitable home for rare plants. It is fully exposed, but has various nooks and crannies wherein may be placed such plants as need a little more shelter than usual; no more than two-and-a-half tons of sandstone were used, so the area is small, so small that I shall soon have to construct another such "pudding," this time in limestone, for many things like Dianthus, Saxifragas, some of the Androsaces, etc., will not thrive in the lime-free soil which I used with the sandstone. The soil consists of equal parts of loam, leaf-mould and granite chips, with a heavy flavouring of silver-sand and kiln dust, which last is the sweepings of the floors of brick kilns, and well-beloved by alpines, although it will grow a fine crop of Marchantia if allowed to become at all soggy.

One of the few plants still in flower is Oxalis hirta, whose deep ruby chalices will expand on a bright day, under the protection of a pane of glass, for this beautiful plant is not quite to be trusted for hardiness if it be left uncovered through the winter's wet. O. lobata, a well-known golden treasure from South America, is almost at the end of its long display of blooms. This plant has a most curious and deceptive habit; in the spring it produces a fine tussock of bright green leaves, which presently disappear, and the owner thereof laments his presumably lost Oxalis; later on, however, up it comes again, this time heralding a display of rich, golden-yellow flowers; it is an invaluable plant, and in a sunny spot and sandy soil will thrive and increase. O. chrysantha is also here; it is not a favourite with everyone, but I must confess to a great weakness for the plant. It is admittedly a ramper in favoured positions, but the trailing shoots of light green, finely-cut leaves are hidden for weeks at a stretch under multitudes of dainty, rather pale yellow flowers, borne on three inch stems. I have to protect it to bring it through the winter here, but on the east coast it is perfectly hardy, and has to be weeded out. It shares, to a marked degree, the great fault of all the Oxalises; directly the sun disappears, so do the flowers close up and demurely hide their glory for the nonce.

In a near-by pocket, filled with very poor, chippy soil, Tulipa saxatilis is just showing through. I have not yet flowered this beauty, which is said to be sparing of its glories in gardens. It is a Cretan species with soft mauve flowers, suffused with yellow at the base of the petals.

Several of the results of a recent collecting trip in Spain and Portugal by my father are here having their first try out, among them being several uncommon Armerias, the best of which is A. Welwitschii, which occurs only on Mount Burrageiros, in Portugal. It is a tight-growing little fellow no taller than A. caespitosa, but with rather longer leaves, which are serrated at the margins; its deep rose flowers are borne on short stems. A. hirsuta is just commencing a late display of flowers, clear soft pink, on six-inch stems, over long, narrow leaves, grey and hirsute. There are several species of Armeria here, so far unnamed, which look very interesting, but have not yet flowered.

Lewisia rediviva is pushing through for its first appearance; this is another plant with a habit, as its name implies, of dying away, only to reappear with renewed vigour and produce the huge flowers, which I can only call "Lewisia-pink," for the Lewisias have a shade of salmon-pink that is peculiarly their own. This plant needs a sunny, well-drained nook, and resents too much moisture during the winter.

Moltkia (Lithospermum) petraea is now settling down, and has made a nice, dwarf bush which looks as though it will certainly flower next year. This is the first time that I have succeeded in making this uncommon little Grecian shrub really at home, and I am looking forward with eagerness to a plentiful display of its blue and purple flowers. Lithospermum intermedium and L. Froebelii are also quite at home, and hold out great promise for next season. Here, also, is another of my triumphs, L. oleaefolium, for never before have I induced this to grow, but now I see that all around my sturdy parent plant bold grey shoots are appearing from underground. It is a rare Pyrenean species, with oval, leathery leaves, silky on the reverse, and flowers of a wonderful, opalescent violet; truly a beautiful plant, but, oh, so difficult! I have not dared to leave my plant unprotected through the winter, so it boasts a large pane of glass all to itself, although it looks sturdy enough to defy the elements at their worst.

Trifolium alpinum is a well-known plant of alpine meadows which is often called to account for its uncertainty of colour, but no such cavil may be made at the pure white form, which I have running about happily, in a fully exposed, well-drained pocket; the flowers are snowy in their purity, and freely produced. Omphalodes lusitanica is another Portuguese introduction of merit, free and almost a rampant grower, with glossy, dark green leaves, and graceful spikes of bright blue flowers, each as large as a threepenny piece.

Origanum Dictamnus is wonderfully effective, with its leaves of thick, grey velvet, and striking, pink, Hop-like flowers, borne in nodding spikes; the felty leaves are best protected from excessive wet.

Richea scoparia, which is doing very well, I know little or nothing of, for it is mentioned only as a name in our text books. It came to me well recommended, and certainly is an attractive little subject with mats of stiff and spiny leaves, in appearance very like an Acantholimon.

A pretty little Umbellifer is Trachymene humilis, which forms a perfectly circular rosette, flat on the ground, of nicely-cut leaves. The flowers are borne on prostrate stems, and make a fringe of white around effective centre rosettes. Leontopodium aloysiodorum gives forth a most refreshing Lemon-scent when rubbed, and is quite distinct from the well-known Edelweiss, with finely-cut leaves, and possessing a shrubby habit.

Dianthuses, on the whole, do not flourish on this lime-free rockwork, two notable exceptions, however, which are making sturdy plants, being D. Napoleon III, and D. Atkinsonii. The latter has a reputation as a "bad-doer" too well-known to need quoting here. The form which I have is called the Wellbrook variety, and was raised in a famous Irish garden; it is, perhaps, of better constitution than the type, and is a glorious colour. D. Napoleon III is an old treasure of gardens, which has almost become lost through over propagation. Asperula hirta, A. lutea and A. suberosa are thriving apace in my treasure box; the last-named is a "miff" of the first water if left exposed to winter wet; the densely woolly growth needs the protection of a piece of glass. A. lutea is more curious than beautiful, for the tiny flowers are a dingy shade of yellow, its only virtue being its rarity.

In a high pocket filled with a good scree mixture, the following Androsaces are making themselves very much at home:—A. carnea. A. c. Laggeri A. praetutiana, A. sempervivoides, and A. Vitaliana; they are quite unprotected and will have to come through the winter as best they can. I think it will be a very good best, for they are glossy-leaved sorts, and appear quite contented so far. A. strigilosa is planted just beneath them. This is the plant which usually passes in commerce as A. foliosa, a much rarer plant, although, perhaps, no more beautiful than the fraudulent bearer of its name, which is handsome enough, with its large leaves and six-inch stems bearing scapes of large, pink flowers. A. Vitaliana passes under so many names that it may be said to answer to any, but although it is variously known as Aretia, Androsace, Gregoria and Douglasia, I believe that the last is correct. It is a lovely plant, provided a flowering form be procured, for alas, there is a form which grows and grows, but never produces the fragrant yellow flowers which stud with such profusion the silvery-grey mats of the good flowering form.

Oenothera caespitosa is sending its questing runners far and wide, and I am truly glad to see this treasure settling down, for the huge, white, changing to pink, flowers are a sight to behold in their season. Another rare plant is Globularia cordifolia var. alba. I have not yet seen it in flower, but if it is as beautiful as its lovely blue type, I shall be well satisfied, and my one plant certainly looks as though it would flower profusely next year, besides giving me numerous rooted offshoots.

The glory of the whole collection this year was Cyananthus incanus var. leiocalyx, a marvellous plant, whose hairy-throated, rather starry bells, of deepest violet-blue, profusely borne on trailing stems, must be seen to be appreciated at their true worth. This also is best protected during the winter when grown outside, and it is an ideal alpine house subject. A plant named Aquilegia salvatorensis fills a corner happily nearby ; it is a gem, just like A. alpina, but barely six inches high, the flowers being the deepest and bluest of blues imaginable, while its foliage is rather dainty and finely cut.

In a very special corner I am trying once again to grow that wretched but beautiful plant, Viola pedata var. bicolor. Each year I try a fresh to establish it, and each year, as the Irishman said, " It dies on me." This year I have hopes, small ones 'tis true, for it was looking so sturdy and well when it went down for its winter rest that I simply cannot believe that it went down to appear no more ; so I live in hope that this year I may be fortunate enough to see, on my own plants, the gorgeous, rich violet and soft lilac flowers, daintily borne on two-inch stems.

There are lots more treasures growing here, but space forbids that I linger longer with them. They may be made the subject of future notes, and perchance included with those I shall hope to make about my " Limestone Treasure Box"—when made. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

NOTICE OF BOOK.

The Rose.

As the Rose enjoys a popularity almost unrivalled by that of any other flower, especially among the owners of the smaller gardens, it is difficult to state that this little book* is redundant, although it would be easy to apply the hackneyed adage about the making of many books on this subject. After a few quite interesting pages of mingled history and legend there is a detailed classified list (in which we regret to see the name " Wichuriana " thus spelled throughout, a trap into which so many unwary nurserymen incontinently fall). The main portion of the book is occupied by cultural directions, of a kind to be of service either to the gardener or to the large grower, the nurseryman or the park superintendent. In one respect the book does cover ground which is, on the whole, not well covered, at any rate in English, for it is a difficult matter to find a book on Rose-growing or flower-cultivation of any kind in this country for the market-man pure and simple. There are numbers of good illustrations, including one coloured plate of Rose Los Angeles. The book is marred by advertisements placed among the text, a piece of parsimony which is not likely to be justified by the price obtained for the space. It is paper-covered, like so many continental books, but is, otherwise, nicely presented.

THE GENUS PRIMULA.

(*Continued from p.* 105.)

KNUTHIANA (Pax). Knuth's P.
(Farinosae.)

A TUFTED perennial species with somewhat thin, oblong-egg-shaped or lance-shaped leaves one-and-a-half inch to two-and-a-half inches long and about one inch broad, pointed or blunt at the tip, tapering to a short, winged stalk ; margins irregularly toothed ; upper surface sparsely mealy, underside densely so. Flower stems mealy, four to six inches tall, bearing a loose or dense, rounded head of about two dozen blossoms, on short, mealy stalks. Corolla about three-quarters-of-an-inch across, rosy-lilac, paler towards the centre, with a deep rose-coloured eye ; lobes broadly heart-shaped, very deeply notched. The blossoms vary much in depth of tint. *Gard. Chron.* (Col. Suppl. Illus.), June 1, 1912.

Grows in damp mountain pastures in northern Shensi, central China.

Var. brevipes (Pax) is smaller than the type ; flower stem longer than the foliage.

Var. major (Pax) is more robust than the type ; flower stem as long as the foliage.

Culture : As for P. farinosa.

KONGBOENSIS (Ward). Kongbo P.
(Farinosae.)

A minute species hardly more than an inch tall, including the flower stem. The rosettes of membranous leaves have spathulate blades about half-an-inch long, gradually tapering to a scarcely distinct stalk ; margins edged with irregular, sharp teeth ; both surfaces clothed with minute, meal-producing hairs. Flower stem slender, about one inch tall, bearing a compact, spherical head of five to ten stalkless, rose-pink, lilac, or mauve blossoms, with a minute yellow eye. Corolla about a quarter-of-an-inch across, with broadly egg-shaped, notched lobes ; tube cylindrical, about one-eighth-of-an-inch long. Flowers in May and June.

Grows in damp alpine pastures in the open, or in the shade of dwarf Rhododendron bushes, in south-eastern Tibet, at 14,000 to 15,000 feet above sea-level.

Culture : Good, rather heavy calcareous loam, in a damp, half-shady spot, with protection from wet in winter, are the conditions recommended.

LACERATA (W. W. Sm.). Fringed P.
(Petiolaris-Chartacea.)

A slender, delicate, perennial species of great beauty, with a tuft of papery leaves one inch to two-and-a-half inches long, with nearly circular blades about one-and-a-half inch across, rounded at the tip, more or less heart-shaped at the base, borne on short, distinct, minutely downy stalks ; margins nearly entire or edged with obscure, rounded teeth ; both surfaces smooth, underside somewhat glaucous. Flower stems usually numerous, slender, minutely downy, six to nine inches tall, bearing from three to seven sweetly-scented, lavender-blue blossoms with an orange eye, on erect stalks about half-an-inch long. Corolla nearly flat, about three-quarters-of-an-inch across, divided into five narrowly egg-shaped, bilobed segments, cut into several narrow, irregular teeth at the tip, giving the petal a fringed edge ; tube cylindric, slightly longer than the calyx, with a distinct ring in the mouth. Flowers in February and March. Not in cultivation.

Grows on the ledges of cliffs in moss, and on banks, usually in loose soil, in north-western Burma, between Shingrup Chet and Akhyang, at 7,000 to 8,000 feet above sea-level.

Culture : Good friable loam, leaf-soil and peat, in a cool, half-shady spot, with protection from severe frost and wet in winter, is indicated.

LACTEOCAPITATA (Balf. f.). Ivory-leaved P.
(Capitatae.)

This desirable deciduous perennial is a sub-species of P. capitata, and is remarkable for the beautiful ivory tint of the meal on the undersides of its leaves. The stout, almost globular rootstock produces a dense, many-leaved rosette of non-downy leaves four to six inches long, with lance-shaped blades tapering to a wide stalk which has a bright red sheath at the base ; margins undulate, recurved, furnished with sharp, narrow, triangular teeth ; upper surface green, slightly mealy, underside densely coated with ivory-coloured meal. Flower stem about twelve inches tall, rigid, coated with ivory-coloured meal and bearing a rounded head of many more or less reflexed, deep purple blossoms Corolla concave, densely mealy, about five-eighths-of-an-inch long, with nearly square, notched lobes ; tube densely mealy, with a ten-lobed ring in the mouth. Flowers in August. In cultivation in 1913.

Grows in masses of loose limestone, in the Sikkim Himalayas, near Lachen and below Moni Samdong, at 9,000 to 13,000 feet above sea-level.

Culture : As for P. capitata, with protection from wet in winter.

LACTIFLORA (S. Turk.). Milk-flowered P.
(Cortusoides.)

An apparently beautiful species with a tuft of deep green, non-mealy leaves with cordate orbicular blades one-and-a-half inch to three inches long, borne on slender, narrowly-winged stalks, frequently twice the length of the blade and covered with fine hairs ; margins divided into several oval, toothed lobes ; upper surface dark green, smooth or slightly hairy on the nerves, undersurface paler, with usually rather long hairs on the nerves. Flower stem slender, three to eight inches tall, downy below, becoming smooth towards the flowers, which are produced in a loose umbel or short raceme and number from three to ten, borne on stalks three-eighths-of-an-inch to three-quarters-of-an-inch long. Corolla pure white, more or less flat, three-eighths-to three-quarters-of-an-inch across, divided into five broadly heart-shaped, notched lobes ; tube violet-coloured, narrowly cylindric, five-eighths- to three-quarters-of-an-inch long, frequently as much as two-and-a-half times as long as the calyx. Not in cultivation.

Grows in alpine situations in the Province of Samarcand, in Turkestan, Russian central Asia.

Culture : As for P. cortusoides. *A. W. Darnell.*

(*To be continued.*)

HOME CORRESPONDENCE.

Partial Sterilisation of Soil.—On reading Mr. John Butler's letter in *The Gardeners' Chronicle* of January 12 (p. 35), I note that he advocates baking soil to sterilise it, rather than the use of steam. This called to my mind an experience that I had just a year ago, which may be of interest to him and others. I was preparing to sow some Tomato seeds, and first began by sterilising my soil. It was a compost containing good loam, leaf-mould and sand, and I sterilised it with steam. The seeds were sown, they germinated approximately one hundred per cent., and the seedlings were potted on into three-inch pots, and eventually became fine sturdy plants. However, I was told that they should have been better still, so, acting upon instructions, I baked some more soil, of a similar mixture to the first, by the common method of placing the soil upon corrugated sheets of iron resting at either end on bricks, with the fire beneath. The soil was stirred continually until considered baked sufficiently. It was then placed aside, after being damped, and the next day seeds of the same variety of Tomato were sown in pans containing the baked soil, and kept under exactly the same conditions as those sown in steam-sterilised soil. The germination commenced in six days, but it was soon evident that they were a failure, as only about fifty per cent. to sixty per cent. of them germinated ; also, the seed-leaves were distinctly yellow, and when the seedlings showed their first rough foliage leaves, the seed-leaves dropped off. However, the seedlings were potted into three-inch pots but were not worth keeping, for when, after having much care bestowed on them, they reached the height of one foot, it was obvious they would never give a satisfactory crop of fruits. The whole of their foliage was yellow, and the plants looked badly starved, so they were destroyed. The first batch of plants—the result of sowing in steam-sterilised soil—gave a crop above all expectations. *Jack Hardy.*

* *Le Rosier, Historique, Culture en plein air et sous verre*, by Ed. Van Cauwenberghe. Federation des Sociétés Horticoles, Rue de la Democratie, 31, Auderlecht-Brussels. Price 10 frs.

——In reply to Mr. T. A. Summerfield's query re steam *v.* baking for the sterilisation of soils (p. 67), there is little room for comparison between the two processes, from a commercial aspect. Undoubtedly baking is the simpler, and, if due regard be paid to temperature, the better method for dealing with the small quantities of soil that can be heated in a container. In commercial horticulture, where acres of soil must annually be sterilised—provided the heating process is adopted—steam is the only practicable agent. It is an advantage, as well as the contrary, that a difficulty is often experienced in maintaining the necessary temperature with steam, while if it were possible to bake such quantities, the maximum temperature might be more readily exceeded. On nearly all up-to-date nurseries an oven for baking small removable quantities of soil for seed raising is used, and since such nurseries are all provided with a steaming plant, this fact constitutes a fair answer to your correspondent's enquiry. It would appear when Mr. Shewell-Cooper suggests that the baked soil "can be used while it is still warm for sowing seeds," he has for the moment overlooked the important factor of aeration. I have never seen any of the soil steamed in a container "removed in the form of mud." Such a result is probably due to the application of wet steam, apparently below 80 lbs. pressure. If a reasonable "dry" steam is used, this difficulty should not occur. *John R. Hamilton, Surbiton.*

Number of Florets in an Exhibition Chrysanthemum.—The interesting note from Mr. A. W. Warner (see p. 107), giving the result of his count of the number of florets in a bloom of Chrysanthemum Louisa Pockett, reminds me that in the autumn of 1897, when a student gardener at the Royal Botanic Gardens, Kew, I assisted the late Mr. William Watson, who was then the Assistant Curator, to count the florets of the blooms of three different types of Chrysanthemum. The result of this count is recorded in a characteristically critical and interesting letter in *The Gardeners' Chronicle* of December 19, 1897, over the well-known signature, *W. W.* The flowers dealt with were one each of a type-like seedling, the Incurved Mrs. R. C. Kingston, and the Japanese Madame Carnot. The first, a small-flowered seedling, was taken as being the nearest approach to the wild form. I have copied the table from Mr. Watson's letter as this gives in the best possible form the results of his investigation.

	Type-like Seedling.	Incurved Mrs. R. C. Kingston.	Japanese Madame Carnot.
Weight of capitulum including six inches of leafless stalk ...	½-oz.	3½-ozs.	7½-ozs.
Number of florets in capitulum	205	1,058	1,753
Length of longest florets			
Width of florets ...	⅛-in.	½-in.	½-in.

As all old growers will remember, Madame Carnot was then considered to be the finest exhibition bloom in cultivation. I have no record of its size but, reconstructing from other records, and the fact that Mr. Norman Davis and Mr. H. J. Jones sent Mr. Watson the blooms, I think I might fairly put it as having a diameter of ten inches. On this assumption the difference in the number of florets is astonishing. *A. C. B.*

Magnolias.—In an interesting article on Magnolias by *W. A.*, the writer exhibits a rather deplorable attitude towards the question of nomenclature. Surely, after the revision of a genus correspondents would be doing a great service by using the revised nomenclature, and, if necessary, the obsolete names could be given in parenthesis. *W. A.* pleads using "the names in general use" in order "to avoid confusion," but he is simply adding to the confusion and widening the existing breach between the systematic botanist and the horticulturist. Something is now being done to clear away the fog and labyrinthine difficulties surrounding the nomenclature of plants. It would go a long way towards the attainment of this ideal if such responsible correspondents as *W. A.* would use the revised and up-to-date nomenclature. *Thomas Blythe, Botanic Garden, Cambridge.*

Gardeners' Pay and Status.—This subject, raised by *B. C.*, in *The Gardeners' Chronicle* for January 19 (p. 51), is an old and interesting one. Surely *B. C.* has enough spirit to let us have his version of the subject. First of all, is *B. C.* a gardener? Grit and initiative are not lacking in our profession, but they have not got us anywhere in the matter of wages. It must be stated at the outset that organisations have so far failed us. The British Gardeners' Association was a failure, not on account of its inability to assist the gardening profession, but owing to the workers themselves not joining it in sufficient numbers. Of course, I realise that one was not wanted in private service in those days if he belonged to such an organisation. Although the above failed, there is no reason why some similar body should not be formed again. If an employer is human he would pay his man a decent, living wage; the average gardener is, in most cases, very much underpaid, and to my knowledge there are many so-called gardeners who get jobs by faked references, etc., and, having once secured a post, they are willing to do any kind of work at a low wage, to keep their job. The prospects of an ambitious young man are not always rosy, unless he has influence behind him to help him after gaining a fair experience. *B. C.* has only to scan advertisement columns to get an idea of the pay frequently offered to gardeners. Could not our large horticultural centres introduce some scheme to protect gardeners in the matter of wages, and stop so-called gardeners obtaining good jobs in gardening after twenty-five years in the police force, and while drawing good pensions, etc.? Why run these horticultural centres to train men and turn them out to obtain the first job that comes along? We look to our great horticultural centres to help in this direction. *R. J. Platten, Bournville.*

——On p. 87 of *The Gardeners' Chronicle* for February 2, your correspondent, Mr. Batty, states there is no guild or association worthy of the name to protect gardeners' interests. If Mr. Batty had been present at the Professional Gardeners' Association's Annual Dinner, held in Leeds, on February 2, he would have changed his opinion. This association will, without doubt, embrace the whole of the British Isles in time; how soon, depends entirely on the British gardener. Mr. Batty's advice to your correspondent, *B. C.*, is exactly what the Professional Gardeners' Association is aiming at—to leave the profession better than we found it. *H. B. O.*

NEW CARNATIONS.

THE following varieties have been registered with the British Carnation Society:—

Wivelsfield Buttercup: Buttercup-yellow; from Messrs. Allwood Bros., Haywards Heath. (Award of Merit.)

Guy Allwood: Pale salmon-pink; from Messrs. Allwood Bros. (Award of Merit.)

Rapture: Silvery-pink; from Messrs. Allwood Bros.

Thomas Ives: Cerise; from Messrs. Stuart Low and Co., Bush Hill Park.

THE ECONOMICS OF FRUIT-GROWING IN ENGLAND.[*]

I THINK I am safe in making the very strong assertion that one of the very few agricultural products of this country which are capable of making large profits, both now and in future, is fruit. Other paying lines are apparently vegetables, flowers, probably Hops, and certainly poultry. From information generally received there does not seem much likelihood of an immediate improvement in cereals, meat and milk.

One reason for stating that fruit is likely to be one of the most profitable lines is that our market is made for us and is an expanding one. Every doctor is preaching the health value of fresh fruit as well as preserved and canned fruit. Fruit is no longer a luxury. The higher standard of living ensures its place on every table, and the *last* step in cutting down expenses is that of reducing the value or volume of food. There is no less bread, meat or milk consumed in this country. The reason of their low prices is the lower cost of production elsewhere, or over-production here or elsewhere. The total consumption of fruit in England is put at £200,000,000.

The first thing a manufacturer of any article does *before* he starts to produce is to ascertain the nature of his market, the chances of that market being glutted, the risks of competition, and to foresee as far into the future as he can. If the omens are favourable he goes ahead, creating his market first, and then supplying the demand thus created.

Unfortunately, the agriculturist cannot vary the nature of his product as can the manufacturer. What has hit the farmer so hard is the lower cost of production, easier financial conditions in other parts of the world and/or over-production.

Fruit cannot be produced at a much lower cost elsewhere, except in the case of soft fruits on the Continent, where it is grown by unpaid family labour, or owing to very low wages, or both.

Dealing with Apples first, it is lamentable that we produce here only one-third of the volume consumed. By means of cold storage we could fill our markets practically all the year round except for the fact that, unlike Canada, Australia and the United States of America, our crops are not sufficiently regular to ensure that continuity of supply that is so essential to the successful sale of any product.

So we shall always need imports, and it is an interesting fact that nearly the whole of our own market has been built up by foreign and Dominion Apples. Without these our own Apples would have been in the position they were fifty years ago, whereas the regular supply of well-packed, sound fruit has resulted in the acquisition of the habit in many thousands of homes of eating Apples every day. If a habit can be formed for the consumption of any article the market for that article is assured, provided, of course, that the standard of quality is maintained. The extension of a habit is largely governed by the ability of the housewife to buy, and consequently, although the cost of a habit is not always considered so closely as the cost of most other articles, the multiplication of such a habit depends somewhat upon price level. In spite of our comparative irregularity of crop, our costs of production and transport are much lower than those of other countries. As so much hinges upon the Dominion and foreign supplies, and such imported produce looms so large upon our markets, it may be well to make a few comparisons.

The position of fruit-growing as regards Apples, at any rate, in other countries is very different. In no country except England is any money being made from Apple-growing.

In some of our Dominions the export of Apples can be carried on only by means of export bounties. All the Australian Apple districts are exporting at prices below the cost of production. It costs the West Australian grower 12s. 6d. to produce and deliver in England a bushel of Apples. This is higher than the average price that produce obtains here, in spite of the fact that those Apples arrive here when our own crop is over. At the same period, cold-stored English Bramley's Seedling average 18s. Canada has a very restricted local market and has to export the great bulk of her Apple crop to Europe. In British Columbia the average cost of production is 4s. 6d. per bushel, freight 4s. 2d., and when brokers' charges are added, the return to the grower is not always enough to cover his expenses. Nova Scotia, the most eastern province of Canada, has a climate most similar to England of any part of Canada. It is almost an island. Its Apples are marketed at a lower cost than those of British Columbia, being packed in barrels containing about three bushels. In spite of this, and in spite of being 3,000 miles nearer our shores, Nova Scotian growers cannot make Apples pay. I was informed recently that the farmers there make up the losses incurred by the fruit from profits derived from their farm and dairy produce, an exactly reverse position to that obtaining here. Many fruit-growing farmers here make their fruit help the losses incurred on the farming portion of their holdings.

---

[*] A Lecture delivered by Mr. W. P. Seabrook, of Chelmsford, at a meeting of The Farmers' Club, held at the Royal Society of Arts, Adelphi, W.C.2, on Monday, February 4 1929.

The United States of America are in a rather better position. They have an enormous home market which they are able to steady by exporting their surplus to Europe. Also they have a much wider range of fruits owing to their more favourable and congenial range of climate. Pears, Plums, Cherries, and Loganberries are widely grown mainly for canning, which is a huge industry in the States. Nevertheless, in spite of all these advantages, Apple-growers in the U.S.A. are not making a living. The Australian and Canadian Apple growers enjoy far more regular crops than the English grower, but their labour and transport costs are immensely higher. They reckon their costs of production at per bushel, whereas I think the only method of costing Apple-growing in this country is per acre. Their regularity of crop enables them to cost per bushel. Our more irregular crops make it advisable to cost per acre, because in large measure our costs go on irrespective of the crop, the only items which are increased in the case of heavy crops being costs incidental to picking, packing, transport and marketing.

Owing to cheaper labour and transport costs here, these items do not loom so largely as is the case abroad, the transport costs alone in America equalling the total cost of production. Moreover, fruit marketed in the States has to bear, on the average, as high a transport charge as that exported, the inland freights of several thousand miles often exceeding the sea freight of exports, the producing areas being in most cases thousands of miles from the consuming areas.

In this country, the lower labour and transport costs much more than offset the advantage enjoyed abroad by reason of regular crops. Their troubles are not only freight costs, but their insect pests are more virulent than ours and the control of these pests much more costly. They have developed very efficient machinery for dealing with pests, but the necessity for practically continual application of sprays and the labour thus involved is a very heavy cost item. The cost of land suitable for fruit in America is very much higher than good fruit land here. Settlers in British Columbia often pay up to £200 for good fruit land, on top of which are imposed irrigation costs. Land fit for fruit can be bought in England at from £15 per acre.

I am dealing with these comparisons in order to try to disprove the widely held belief that Apple-growing abroad is more profitable than here. The enormous volume of imports leads the casual observer to infer that Apples can only be produced successfully in kinder climates than ours, an impression strengthened by knowledge of the regularity of crops in those kinder climates. Regularity of crops is a valuable asset, but when it is accompanied by such high costs of production and transport as to render those crops unprofitable, the glamour recedes. Another cost attending the marketing and movement of Apples in America which is not regularly incurred here is that of cold storage. Our more temperate climate enables us to store naturally the great bulk of our autumn and winter Apples, thus enabling us to extend the marketing season and steady prices.

Even if we have to cold-store, the cost is only 1s. 0½d. per bushel for six months. We have varieties that are eminently suitable for cold storage, and by reason of their texture will stand up as long or longer than any imported Apple. The reason so little cold storage has been done in the past is that, owing to the lack of continuity of our marketing and the absence of organised marketing, buyers have stopped asking for our varieties immediately the normal season is over, and have gone straight on to imported Apples, which they know will be available for a long period.

The position at present is that we could easily produce every Apple needed until Christmas and with cold storage carry on regular supplies until the Australian crop comes in April. In the U.S.A. organised marketing is carried out to a large extent, consuming areas being fed as and when required, up to saturation point, and no farther.

England could supply her own needs very much more than she is doing to-day, and the result would not be a slump in prices, but replacing much of the foreign fruit with English. If the time should arrive when there was over-production, we have world markets for English Apples. Our merchant service is the finest in the world, ships go direct regularly to all parts, our freights would be lower than for American produce, and our season enables up to ship Apples to other countries in their off season, or to such countries as do not produce Apples. My own firm has been exporting Apples to South Africa and the Argentine since 1906, but the freight cost just after the War rose so sharply that we put boxed Apples on to the home market, with the result that we have built up a very strong demand at home. This export business can be picked up again at any time, and will be so soon as there is any sign of over-production here. Successful marketing of Apples, and, in fact, of all fruit, depends absolutely upon standardisation. The foreign and Dominion growers have built up the whole of their business by means of standardisation and organised marketing. Growers in England have not yet touched the fringe of standardisation. Proximity of markets, the ease with which low and ordinary grades can be sold, and lack of competition in the past, have all combined to delay that standardisation which is so desirable and in which our overseas friends excel. The time has now come when low grades are becoming unsaleable. The public has a choice of fruits from the whole world, and will now buy only such fruit as is standardised and may be relied upon. Just as soon as English growers standardise, pack and grade properly and put on the market fruit as reliable as that which comes from abroad—then, and then only, will that produce take its proper place. It will always make more money by reason of its superior flavour, sub-acidity and general edible quality. But none of these factors have any effect unless the fruit is presented as well as the imported fruit. When it is so presented, it makes higher average prices than any imported fruit *without exception*.

Our markets do not see low grades from abroad. They are either not grown or are not marketed. Until we refrain from growing or marketing our low grades, we shall not regain any appreciable share of the business.

Unfortunately, much of this low-grade fruit sells for something, especially in those areas in which the purchasing power is low. If such low grades are marketed they should be confined to these poorer areas and not come into competition with our better grades. The period of sharpest competition with overseas Apples is during September and October. During those months our Worcester Pearmains, packed, graded and boxed in exactly the same way as Californian Gravensteins, make from 5s. to 10s per bushel more, even in the ports of entry, such as Liverpool. In October, Bramley's Seedlings make from 2s. to 5s. more per bushel than York Imperials from the U.S.A. Numerous instances could be given of direct competition, in which the balance was enormously in favour of the home article. One such occurs to me which happened in Covent Garden Market only last summer. Our Worcester Pearmains were sold from one wholesaler's stand at an average price of 18s. per bushel box. At the adjoining stand on the same day imported Gravensteins and Jonathans were being sold at 8s. But the English fruit must be as well-grown and as well-packed as the imported fruit. It will not sell on quality or flavour alone. If the English Apples look as good or as sound (not necessarily as red) as the foreign Apples, their quality will always give them predominance. English growers say, "Why pack Apples which have to travel a dozen or fifty miles in the same way as Apples packed to travel many thousands of miles?" That is the wrong attitude to adopt. The fact is, we have to meet Apples so packed *here*, irrespective of how many miles they have had to come. In other words, we must adopt the same tactics and present our fruit in the same way as the exporter does. Then the intrinsic quality of our fruit will always bring a higher price. We have now in use in this country grading and sizing machinery. Our box-wood costs less because we are nearer Scandinavia. We can produce Apples cheaper and better than any foreign country, if not with the same regularity. Our transport costs at least 3s. per bushel less. Counties near London can get their Apples on the market at a cost of 4d. per bushel, and the longest journey—from Essex to Glasgow—costs only 1s. 3d. Our scientists have discovered quicker and cheaper methods of controlling pests than the Americans. Our methods of fruit-growing have improved immeasurably in the last few years. That is to say, our knowledge has vastly increased and, fruit growing is not now the risky problem it once was.

It is true that the old-established English grower cannot easily change his varieties, but he is now in possession of much information regarding cultural practices, such as thinning, spraying, manuring and marketing which, if intelligently applied, will enormously enhance the value of his crops.

More progress has been made in the science of fruit-growing during the last ten years than was made in the previous century. As regards thinning, we must copy the Dominion and American growers. They would no more dream of omitting this operation than they would that of spraying. Thinning eliminates most of the inferior grades and brings up the graded level of the remainder without the reduction of a pound in total weight. It merely distributes the same weight over fewer and, therefore, larger Apples. The introduction of winter tar-oil washes removes with one application those two terrors of the past, aphides and caterpillars—or, rather, I should say, all insects (except red spider) whose eggs are present on the trees in winter. Fungus pests (among which black scab is the worst) can now be controlled in larger measure than ever before. Much advance has been made in the science of manuring, particularly by reason of the work done at the Long Ashton Research Station.

Invaluable work has been done at East Malling as regards stocks for fruit trees. That work is in its infancy, but constitutes a very real advance. Plant physiologists are at work at both these stations, Swarbrick's work at Long Ashton on the effect of scion on stock being of much interest. The recently developed and now widely applied practice of ringing fruit trees according to Gardener Brothers' method at Wisbech bids fair to revolutionise commercial Apple-growing in this country, and may be the means of getting more regular crops, which we so badly need. The invaluable Reports of the Ministry of Agriculture's Markets Branch on marketing problems need leave no grower in ignorance of the science of modern marketing methods.

In short, the quality and quantity of fruit needed to regain a much larger share of our own markets can now be obtained with much greater chance of certainty than ever before, *if growers care or are in a position to put such knowledge into practice.*

Now a few words as to the financial position of Apple-growing to-day. Unfortunately, the data as to costs of production are very meagre. Very few growers in the past have kept accurate costings, and very few have kept even particulars of revenue. They are very like farmers in this respect, having no love of accounts and in many cases neither time nor inclination to keep them. They are thus unable to ascertain which crops or varieties are giving the best profits.

Our own position is similar in that while we have accurately recorded the results given by all our fruit crops and ascertained the best method of marketing for each individual crop over a period of twenty-five years, owing to the complications incidental to another business, *i.e.*, fruit tree propagation as apart from fruit growing for market, our costs have not been accurately kept. We have often employed highly paid men from the nursery side on the fruit side because they were available, but whose rate of wages would not otherwise warrant their employment; the orchards are hopelessly mixed up with the nursery land and are being extended every year; buildings, office work, supervision, and many other overheads have overlapped both businesses so inextricably that the task of separate costings appeared insuperable. Therefore our costs of production of fruit are based upon examples and frequent tests only, and not on any sustained system of accounting. In 1925, we bought a farm of 300 acres, most of which is now planted down to permanent fruit and is worked by a separate staff, separate implements, has its own buildings, and the accounts of which have been accurately kept from the start. So we shall know one of these days the actual cost of establishing fruit, bringing it to maturity and eventually the exact financial position.

(*To be concluded.*)

FRUIT GARDEN.

WOOLLY APHIS.

WOOLLY aphis (Eriosoma lanigera) attacks the Apple chiefly, and the Pear occasionally. The aphides pierce the bark and obtain their nourishment entirely from the sap,and when they are present in numbers so much sap is withdrawn that the tree is weakened considerably. They also attack the roots in the same manner, and this renders their extermination rather difficult; the leaves and fruits are rarely attacked, but there is probably a constant migration going on between roots and branches. The woolly aphis may be recognised easily in an orchard by the masses of white, woolly substance formed by the larvae and females.

Various methods of control and eradication have been put forward from time to time, such as banding the trees in the same manner as for winter moth, to prevent the upward migration of the aphides in spring; using a strong caustic winter wash and driving the spray, with some force, into every crack and crevice; and painting the affected parts with methylated spirit, or paraffin, if the trees are old, using a stiff brush and working the spirit into any cankered parts. A mixture of lime-sulphur and nicotine is also recommended, employing the lime-sulphur at a strength of one in twelve, adding one ounce of nicotine for each twelve gallons of the diluted spray.

So far, I have not seen a painter's blow lamp advocated, yet it is a most effective means of eradicating this pest above ground. The lamp is charged and lighted, and so long as the operator directs the flame with very rapid movements all over the trunk and the affected parts, no injury to the tree will result, and not an aphis will be left alive, as the flame is most penetrating. The trunks should then be grease-banded, and the grease kept in a sticky condition. If the infestation is of long standing, the roots of the trees will probably be affected, and measures above ground are therefore insufficient. Probably the only control in such cases is the injection into the soil of carbon bisulphide during March or April, when the soil is in a fairly dry condition. This substance should not, however, be allowed to come into direct contact with the roots, and, being of a highly inflammable nature, is probably best left alone. Instead, the grease-bands should be employed throughout the year, and the parts below them sprayed occasionally with nicotine or paraffin emulsion. *H. H. Cook.*

POTATO NEWS.

MR. WILLIAM STUART, of the Department of Agriculture at Washington, is known to many in this country, and to a number of his friends he has recently sent a *Report of the Research Committee.* This report is a resumé of the work which has been done on Potatos in the United States and other countries during 1927. Many problems are touched in a most interesting way, but the difference in the U.S.A. weather conditions and our own must always be kept closely in mind. Bushnell, who works in Ohio, calls attention to the fact that for two months after harvest, Potatos are in a true dormant state, and that during this resting stage they remain dormant and firm at any ordinary storage temperature, but after that they must be kept in a temperature below 41°F. to prevent sprouting.

The Potato: Its History, Varieties, Culture and Diseases, by Thos. P. McIntosh, of Edinburgh—much of which appeared in these columns—is noted as the most recent addition to Potato literature, and it is declared that parts I, II, and III are especially interesting, and contain much of use to American Potato growers.

PHYSIOLOGICAL RESEARCH.

This seems to have been mostly confined to experiments in the breaking down of the resting period of tubers by means of chemical treatment, and it is said that the results to date give promise of important practical applications. The chief experiment was carried out at Maryland Experimental Station by Mr. White. Potatos were dug mature, on July 18, and treated with ethylene chlorhydrin, and planted on August 1. The plants appeared above ground in three weeks; on September 8, the best lot showed an eighty-two per cent. stand. The crop was dug on November 10, after the tops had been killed by frost; a fair crop of good-sized tubers was produced. Seed tubers untreated did not show above ground until November 1.

Dr. Salaman, of Cambridge, is reported as also experimenting with the chemical treatment of tubers from a different angle.

Two pages are devoted to "Contributions to Potato Breeding in 1927." The chromosomes of the Potato have received special consideration. It is stated that three workers arrived independently at the same conclusion, "and it is almost certain that twenty-four is the basic haploid number in the Potato."

Reference is made to a paper by K. O. Muller, which has a more direct bearing on the practical phases of Potato breeding. This is described as "an excellent piece of work in experimental Potato breeding, dealing with the genetic characteristics of varieties of different maturity." It is stated that the year 1927 was productive of very little scientific investigation bearing on the soils and fertiliser relationship of the Potato. I am not surprised at this. In the actual growing I do not think we have anything to learn from American, French or German methods.

In the "Summary of Contributions to Potato Pathology," much space is given to virus diseases. As every Potato grower is now keenly interested in virus disease problems, I quote rather freely from this part of the report.

"In Europe, the theory of degeneration of Potato varieties as a result of long continued asexual propagation died hard. It has been succeeded in part by a theory which imputes to the environmental conditions under which the seed tubers are produced, a dominant influence on the vigour and productiveness of the ensuing generation aside from any consideration of infection with virus and other diseases. This theory does not deny the existence of virus diseases or their inheritance through tubers, but it holds that the pseudo-hereditary character of degeneration in Potato stocks is mainly the hold-over effect of unfavourable ecological conditions under which the seed tubers developed. Admitting the importance of a favourable environment for seed Potato production, it nevertheless appears that this theory, like the asexual degeneration theory, assumes far too much, and its adherents in Europe, as elsewhere, have not been able to support their claims against the increasing evidence of the predominant rôle of virus diseases."

Murphy and McKay have found that in Ireland Potatos are practically free from the more serious types of degeneration, except for localised areas near the principal cities. Heribert-Nilsson observes that although leaf-roll is so prevalent in certain parts of Sweden that the variety Magnum Bonum is eliminated by disease in four years, a locally selected variety has remained apparently free from disease and vigorous after eleven years of cultivation in the midst of susceptible varieties.

Jaczewski reports, as the result of a Potato disease survey in Russia, that all the various types of mosaic, leaf-roll and spindle tuber occur in that country, but chiefly in the regions where foreign Potatos have been imported for cultivation. The native varieties still appear to be comparatively free from degeneration, and may be more or less resistant to those diseases. It is possible that considerable value would accrue in this country also from an organised search for local varieties which maintain their vigour through long continued cultivation, indicative of resistance to virus diseases.

FUNGUS DISEASES.

Potato wart continues to be a subject of considerable interest to European plant pathologists, it is stated. Reference is made to Miss Glynne's work as follows:—

"In 1926, Miss Glynne found that certain British varieties of Potatos which had been officially certified as immune to wart, developed very small growths when heavily inoculated with the wart organism. In these growths the development of the fungus appeared to be arrested before it produced resting spores, but it is possible that the summer spore stage was produced in some cases. At Rothamstead, Roach continued experiments in grafting together in various ways, roots, shoots and tubers, respectively, of immune and susceptible Potato plants, but found that the resistance or susceptibility of tubers produced on the experimental plants was in no wise altered from the normal reaction. Evidently resistance to this disease does not depend on some substance that circulated in the plant and can traverse a graft fusion layer, but it is due to an innate and fixed property of the cells, probably of the protoplasm."

The work of Millard and others in Britain on the relation of green manuring to the suppression of scab is referred to. We are told that they have recognised twenty different types of Actinomyces, of which eleven can produce scab on Potatos. "These authors showed experimentally that the effect of green manure in reducing Scab depends on the non-parasitic species of Actinomyces, and perhaps other bacteria which the decaying plant residue introduces into the soil, or cause to flourish at the expense of the parasitic types. Where green manure is without effect it is suggested that the proper saprophytic organisms are naturally lacking in the soil."

Spraying for the control of late blight is dealt with, and the most interesting point is the statement that a small admixture of tannin greatly increased the suspensary capacity and adhesiveness of Bordeaux.

I read with great interest the notes on internal brown spot by Millard, and those on "Blue Discoloration," by Botjes in Holland. The former trouble has long been known to growers as "sprain."

A Miss Savartz has discovered a type of internal brown spot of frequent occurrence in the Dutch West Indies, which is different from the European "sprain." She adds that lack of lime in the soil and the over use of stable manure are said to increase the disease. Observation on these lines would be useful in this country where "sprain" is prevalent. Dr. Botjes' "discoloration" seems to describe a disease which in some districts is affecting stocks of Golden Wonder—they are affected, as he describes, with a bluish-black discoloration under the skin, at the stem end, or grey markings may extend through the tuber. In soils with a deficiency of potash, this disease has been found to be most prevalent.

I hope this resumé will interest Potato growers. *William Cuthbertson, Duddingston.*

SOCIETIES.

ROYAL HORTICULTURAL.

February 12.—In spite of the severe wintry weather, there was a very bright show of flowers in the Horticultural Hall, Westminster, on the occasion of the fortnightly meeting of the Society. It must have been a serious undertaking to transport greenhouse plants and forced shrubs successfully from the warm glasshouses, but our horticulturists are accustomed to pit their brains and skill against adverse weather conditions of all sorts, and so it is more than probable that they rarely receive the appreciation their efforts warrant. Orchids were shown quite as extensively and as meritoriously as a fortnight ago, and in much the same genera. The Orchid Committee recommended one First Class Certificate and two Awards of Merit to novelties. Large-flowered Cinerarias, greenhouse Primulas, Carnations, forced shrubs and alpines were the chief floral features. The Floral Committee recommended two Awards of Merit to novelties. The Narcissus and Tulip Committee met for the first time this season, but had no novelty to consider. There was a very good group of early Tulips. There was nothing of moment before the Fruit and Vegetable Committee, but in the hall there were two small collections of well-kept Apples. The exhibits of garden paintings were, as usual, quite interesting.

Orchid Committee.

Present: Mr. Frederick J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Secretary), Col. Stephenson Clarke, Mr. J. E. Shill, Mr. J. Wilson Potter, Mr. S. Flory, Mr. Charles H. Curtis, Mr. Stuart Low, Mr. A. Dye, Mr. Fred. K. Sander, Mr. T. Armstrong, Mr. E. R. Ashton, and Mr. A. McBean.

First Class Certificate.

Miltonia Lycaena, Orchidhurst var. (*M. Princess Margaret* × *M. Lord Lambourne*).—A splendid Orchid, with flowers of the largest size and finest form. The colour is rich ruby-red, shading to reddish-rose, with a fairly wide white margin—this colouring applies to the wide lip and the petals. The sepals are pointed, white, with reddish-rose shading and lines at the base. The mask is yellow and orange, and the radiating lines are margined with pale rosy-white. Shown by Baron Bruno Schröder (gr. Mr. J. E. Shill), Dell Park, Englefield Green.

Awards of Merit.

Odontioda Matador (*O. St. Andre* × *O. Leander*).—In this hybrid the shapely, substantial blooms are of deep brownish-crimson colour. The lip is of similar colour, with yellowish markings at the base and a white, red-flecked apex. Shown by Messrs. Sanders.

Cymbidium Vesta (*C. Alexanderi* × *C. insigne Sanderi*).—A very pretty and dainty hybrid with flowers of good size pleasingly set in a semi-pendant spike. The colour is pale pink, with numerous rose-red lines and spots on the lip. Shown by Messrs. J. and A. McBean.

Groups.

Notwithstanding the bitter weather of Monday and Tuesday, there was an excellent display of Orchids at Vincent Square, and one which surprised and pleased those who came to the R.H.S. Hall.

S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton, contributed an interesting group, wherein Dendrobium delicatum, with two dozen spikes of its white flowers, constituted the central feature; it was an unusually fine example. (Cultural Commendation.) Odontoglossum Penelope, O. Duvivierianum, O. Insleayi var. splendens, th handsome old O. bictoniensis, Lycastes in variety, Platyclinis glumacea, Cypripedium Fairrieanum, Coelogyne intermedia and Saccolabium bellinum were included among the other Orchids in this charming display.

Messrs. J. and A. McBean exhibited fine spikes of Odontoglossum mirum, O. Phoebe, O. Thyades, O. Red Admiral, O. Rosina var. coeruleum and O. Vuylstekeae. They also displayed good examples of Cymbidium Omar, C. Pearl, C. Vesta, C. Erica Sander and C. Alexanderi, besides Odontioda Enchantress, Oncidioda Cora, Laelio-Cattleya Profusion, L.-C. Beatrice, Cattleya chocoensis alba, with fourteen flowers; and the brilliant Epiphronitis Veitchii.

Messrs. Sanders devoted considerable space to Cymbidiums and Lycastes, the former including C. Erica Sander, C. Magali Sander, C. Swallow and C. Hookerianum. Besides these, the St. Albans firm showed Angraecum cylindricum, Trichopilia sanguinolenta, Ada aurantiaca, Phalaenopsis Schilleriana var. Vivid, and the quaint Bulbophyllum Dayanum. Numerous good Cypripediums and fine spikes of Oncidium splendidum were included in the display.

Oncidium splendidum also figured prominently in the group exhibited by Messrs. Cowan and Co., and with these were Cymbidium Erica, C. Coningsbyanum, Cattleya Tityus, in fine form; a four-flowered example of the bright C. Woltersiana, Odontioda Grenadier, Odontoglossum Doris, and such fine Cypripediums as C. Royal George, C. Vashti, C. Nora, C. Maudiae var. magnificum and C. Croesus.

A few Orchids were shown by Messrs. Stuart Low and Co., the chief being Cymbidium Castor, C. Romulus, C. Lucastes, C. Coningsbyanum, Zygopetalum Mackayi, Cypripedium Maudiae, C. A. de Lairesse and Brasso-Laelio-Cattleya Highlander.

A beautifully grown plant of Platyclinis glumacea figured in a small group displayed by Mr. J. Evans, but Cypripediums were the main feature. These included C. Makeda var. The Prince, C. Lady Dillon, C Corsair and numerous unnamed hybrids from C. Christopher. Cypripedium Mrs. Carl Holmes, C. Chesham and C. Edzell were shown by Messrs. Black and Flory.

Gus Mayer, Esq. (gr. Mr. Cottam), Whistler's Wood, sent a few Orchids, the best being Odontioda Ramona and Cypripedium Perseus Alpha, Whistler's Wood variety.

Floral Committee.

Present: Section A.—Mr. J. F. McLeod (in the Chair), Mr. Arthur Turner, Mrs. Ethel M. Wightman, Mr. R. Findlay, Mr. J. M. Bridgeford, Mr. D. Ingamells, Mr. M. C. Allwood, Mr. James B. Riding, Mr. A. E. Vasey, Mr. W. B. Gingell, Mr. D. B. Crane, Mrs. Helen Lindsay Smith, Mr. Charles E. Pearson, Mr. G. W. Leak, Mr E. R. Janes, Mr. Courtney Page and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Gerald W. E. Loder (in the chair), Mr. C. Williams, Mr. G. Reuthe, Mr. F. G. Preston, Mr. W. B. Cranfield, Mr. Reginald Cory, Mr. Mark Fenwick, Lady Beatrix Stanley, Mr. E. A. Bowles, Mr. L. R. Russell, Mr. E. H. Wilding, Sir William Lawrence, Bt., Mr. T. Hay, Mr. Charles T. Musgrave, Mr. Clarence Elliott, Mr. W. J. Bean, Mr. A. Bedford, Hon. Henry D. McLaren, Mr. R. C. Notcutt and Mr. N. K. Gould, Secretary.

Awards of Merit.

Gordonia Lasianthus ?—The award was made subject to revision of name, and there certainly seems room for an element of doubt as to its accuracy, for the specimens shown did not wholly agree with the illustration, t. 668 in *Bot. Mag.*, of a flowering spray. In several respects the sprays shown agree better with the "Camellia axillaris" of *Bot. Mag.*, t. 2,047. According to the *Index Kewensis*, Camellia axillaris is a synonym of Gordonia anomola. A good illustration of a spray of Gordonia anomola, which flowered at Kew, appears in *The Gardeners' Chronicle*, of June 23, 1917. In the specimen which received an award the leaves were coriaceous, lanceolate-spathulate, slightly dentate along the outer halves, pale green and shining above. The flowers were borne in axillary clusters of three or more. The individual flowers were nearly sessile and rounded. The short calyx was brownish and cupped, the corolla, also cupped, was white, crinkled at the margins, and of semi-transparent delicacy. There was a good cluster of yellow filaments. Probably on account of the coldness, we could not detect the fragrance which is generally present in both Gordonia Lasianthus and in G. anomola. Shown by Lt.-Col. Messel, O.B.E. (gr. Mr. J. Comber), Nymans, Handcross, Sussex.

Rhododendron K.W. 6273.—This is a beautiful Chinese species which apparently flowers when quite young, as the three plants were dwarf specimens less than a foot in height. The ovate leaves are two inches long by three-quarters-of-an-inch wide and freely furnished with brown hairs. The flowers are solitary, round, milk-white, and two inches across; the filaments are white, with chocolate anthers. Shown by Lionel de Rothschild, Esq., O.B.E. (gr. Mr. A. Bedford), Exbury, Southampton.

Groups.

The centre of the hall was filled with an exceedingly attractive circular group of large-flowered Cinerarias, arranged by Messrs. Sutton and Sons. The many plants were exceedingly well-grown and illustrated a most desirable strain of this popular greenhouse plant. The arrangement was a series of circles of either a distinct variety or of mixed colours, set in moss and relieved by dwarf Palms. Of the colour varieties Pink Pearl, Royal Blue, Light Blue, Brilliant Ruby, and Blue with white zone, were especially attractive.

On a large side space Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, set up a very extensive collection of large-flowered Cinerarias which also displayed first-rate cultivation. Some of the plants showed slight signs of the stress of the weather, but, in both cases, it is a tribute to those responsible that so many large plants were safely transported to the show. In the glasshouse, Mr. Wallrock's Cinerarias must have been very beautiful.

A goodly stretch of tabling was filled with greenhouse Primulas and Freesias from the Mental Hospital Gardens (gr. Mr. W. J. Jennings), Napsbury. The many Primulas were of the strain selected and grown at Napsbury over a considerable period, and it was particularly good. Messrs. Stuart Low and Co. grouped large bushes of Camellias with Mimosas (Acacias), and dwarfer Epacrises and Ericas. Alongside they had a good collection of Carnations of such varieties as Master Michael Stoop, Thomas Ives, Melchet Beauty, Brilliant, Daphne and Kathleen.

In their large group of Carnations, Messrs. C. Engelmann, Ltd., included vases of Rouge, Mrs. A. J. Cobb, Master Michael Stoop, Laddie, and Supreme. Messrs. Allwood Bros. had stands of Topsy, Eldorado, Maud Allwood, Red Laddie and a selection of Dianthus Allwoodii varieties.

An imposing group of forced flowering shrubs was arranged by Messrs. L. R. Russell, Ltd. They had tall, graceful examples of various Pyruses, Prunuses, Lilacs and Magnolias, with bushy specimens of Viburnum Carlesii, Forsythia spectabilis and Ericas. Messrs. Hodgsons had a small exhibit of Lilacs and alpines. Mr. George E. P. Wood staged Skimmias, Viburnum Tinus (Laurestinus), and Conifers, with Snowdrops, Crocuses and other spring flowers.

In an extensive collection, Messrs. Wm. Wood and Sons grouped Cryptomeria japonica compacta, Prunus triloba plena, Forsythia spectabilis and Ericas, behind well-flowered Primula Barrowby Gem, early Narcissi and Irises. The Misses Hopkins had a neat paved garden planted with blue and yellow Primroses and Iris reticulata. Messrs. Patricks showed many useful Coniferous and other hardy shrubs.

Especially good spring flowers were shown in quantity and tastefully arranged by Messrs. Barr and Sons. Their early Narcissi included nanus, a pretty N. minor seedling, N. minimus and N. cyclamineus. Among the many dwarf Irises were Rosalie, Princess Louise, reticulata and sind-pers. They also had several showy patches of Crocuses with brilliant yellow, purple, white and striped flowers. Messrs. J. Cheal and Sons had a spring group of Daphne Mezerium, Hamamelis, Crocuses, Muscari and dwarf Irises. Messrs. M. Prichard and Sons again showed small pots of various Saxifrages.

A very attractive rockery made by Messrs. Wm. Cutbush and Son, was planted with a showy group of Azalea Hinomanyo, many Crocuses and Irises. The Lee Green Nurseries

Ltd., had a small rock pool. Messrs. Tuckers showed Primula Winteri, Saxifrages, and Raoulia australis. Messrs. Hollamby grouped Gaultheria procumbens, furnished with its bright berries, Primula Purple Splendour, and small Conifers.

Messrs. Waterer, Sons and Crisp arranged Forsythia spectabilis and other shrubs with Crocuses, Iris reticulata, I. Tauri and Anemone blanda. In his exhibit, Mr. George G. Whitelegg displayed forced ornamental Cherries, Azaleas, Skimmias and many shapely Conifers. The Orpington Nurseries showed Conifers. suitable for the rock garden and some Ericas.

Exhibits of paintings were quite numerous, but the varied displays of sundries which have characterised the shows during the last few months were not in evidence at this meeting. Among the exhibitors of paintings were Miss Ough, who had, as a special feature, an excellent rendering of an old world cottage garden at Lynmouth, Devonshire; Miss E. Francis Drake, Miss Ellen Warrington, Miss Margaret Linnell, Mr. Herbert George, Miss Agnes Strickner, Miss Edith A. Andrews, Mrs. M. Townsend, Miss G. E. Bayley, Miss Eva Kirkpatrick, Miss Alice F. Wilkinson, Miss Winifred Walker, Mrs. Henry Spencer, Miss Marion Broom and Miss Julia Fielding. Garden designs were exhibited by the Lee Green Nurseries.

Narcissus and Tulip Committee.

Present: Mr. George Monro (in the chair), Mr. G. W. Leak, Mrs. Violet Brodie, Mr. W. F. M. Copeland, Mr. W. B. Cranfield, Mr. Charles H. Curtis, Mr. William Poupart, Mr. Peter R. Barr, Mr. F. A. Secrett, Miss E. Willmott and Mr. E. A. Bowles.

As was expected for so early in the season, there were no novelties exhibited before this Committee.

Groups.

The only exhibit with which this Committee had to deal was an attractive group of Tulips, staged by Messrs. James Carter and Co.; the Tulips were arranged in an undulating and gently sloping mound with a background of Conifers. For so early in the season, and considering the weather conditions experienced of late, the blooms were in excellent condition, the most striking sorts shown being Prince of Austria, Grand Duc, Ibis, Gullinan, Flamingo, Red Admiral, Brunhilde, Mon Tresor, Vermilion Brilliant, McKinley, De Wet and Queen Flora.

Fruit and Vegetable Committee.

Present: Mr. James Cheal (in the chair), Mr. W. Poupart, Mr. G. F. Tinley, Mr. W. F. Giles, Mr. W. J. Earl, Mr. H. Prince, Mr. H. Markham, Mr. Edwin Beckett, Mr. A. C. Smith, Mr. E. A. Bunyard, Mr. E. Laxton and Mr. A. N. Rawes, Secretary.

A seedling Apple, named Bowdens Seedling (Cox's Orange Pippin × Cornish Gilliflower), was shown by Mr. G. W. King, Sidcup, Kent. The fruits were of good appearance and richly coloured, but as they were past their best, the Committee was unable to deal with them.

Groups.

An interesting feature of this meeting was the collection of old, and in many instances uncommon, varieties of Apples staged by Messrs. George Bunyard and Co., Ltd. A number of them were continental varieties, and among the most interesting were Reinette Pederstrop, Court Pendu Plat, Reinette Grise de St. Ogne, Reinette de Versailles, Golden Russet, Sweet Laden, Winter Pearmain, Yellow Belleflower, Selig's Golden Reinette, Buff Coat and Api Gros Blanc.

Apples were also shown by Messrs. J. Cheal and Sons, Ltd., the varieties represented in their small group being Annie Elizabeth, Sturmer Pippin, Adams' Pearmain, Encore, Beauty of Kent, Cornish Aromatic, Sandringham, Crawley Beauty, and the recently introduced dessert variety King George V. The fruits displayed were splendidly coloured and in excellent condition.

NATIONAL CHRYSANTHEMUM.

There was an average attendance of members of the National Chrysanthemum Society at the Essex Hall, Strand, London, on Monday, February 4 last, on the occasion of the Annual General Meeting. In the absence of the President, the Hon. Sir John Ward, Mr. E. F. Hawes, Chairman of Committee, was elected Chairman of the meeting. After the usual preliminaries, the Committee's Report and the Cash Statement for the past year were considered and, as they contained records of good work done and an excellent financial position, both were adopted unanimously. In proposing the adoption of the Report and Accounts, the Chairman referred to the excellence of the exhibits at the annual show, and said that he felt sure everyone was delighted to find that the President's veteran gardener, Mr. C. Beckett, was still able to more than hold his own with younger men, as the blooms which he staged were of superlative quality. He felt that the Society was indeed fortunate in having a President who supported it so whole-heartedly in every way. As was stated in the Report, the show of last November was probably the last the Society would hold in the old hall, but the Executive Committee looked forward confidently to the results of the shows which would in future be held in the larger and new hall.

Mr. Hawes, continuing, said that the fact that one-hundred-and-twenty-five new varieties were submitted to the Floral Committee during the year showed the value raisers put on the Society's awards, which were the hall-mark of the Chrysanthemum world. That, out of the number mentioned, only forty-eight varieties received awards was proof of the high standard the Floral Committee rightly set.

The recently instituted trials of early-flowering Chrysanthemums was reviewed, and it seems that Mr. Hatch, who was elected Trials Superintendent, has in his nursery at Cookham, Bucks., nearly three hundred varieties. Already cuttings have been inserted, and it is expected that, as the many varieties will now be grown under identical conditions, the trials this year will be of great value and interest. In due course they will be inspected by the Sub-Committee, which will report its findings and recommendations.

During the year under review, the Society lost, in the death of Mr. H. J. Jones, one of its oldest and most generous supporters. As a tribute to his memory, the meeting stood in silence for a time. Mention was also made of the illnesses of Mr. William Howe and Mr. Mark Mills, two old members of Committee, and sincere hopes were expressed for their speedy and full recovery.

The proposal to publish an "Annual" during the year will be welcomed by members generally, and country readers in particular. The Chairman explained that the cessation of the publication was not due to parsimony, but to the need for waiting until the finances were in such a stable condition as would justify the expectation of continuing the publication regularly in the future.

As already stated, the accounts show an excellent condition. There is a balance on the year's receipts of £170, and the Society now has a total balance of £296 12s. 11d., "being surplus of assets over liabilities." One very encouraging feature of the statement is that it contains the large sum of £31 16s. 0d. derived from arrears, largely of subscriptions. As the Chairman pointed out, the satisfactory financial condition was only obtained through hard work and he was sure everyone would realise that it was entirely due to the enterprise of the secretary, Mr. C. H. Curtis, whose re-election was enthusiastically carried, as also was that of the Hon Sir John Ward as President for the year. Mr. E. F. Hawes was re-elected Chairman of Committee, Mr. Percy Gragg was elected Vice-Chairman, and Mr. David Ingamells was re-elected Hon. Treasurer. As Mr. William Howe and Mr. Mark Mills expressed the desire to retire, their places on the Committee were filled by the appointment of Mr. L. Mills and Mr. W. Yandell; the other members of Committee who were retiring by rotation were re-elected.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on Friday, February 1, 1929, at Houldsworth Hall, Deansgate, Manchester, the members of Committee present were: Messrs. H. Astley Bell (in the chair), A. Burns, A. Coningsby, J. Evans, D. McLeod, W. J. Morgan and H. Arthur, Secretary.

Awards of Merit.

Cypripedium Helsa var. Ingrid (*C. Helen II* × *C. Satyr*).—A fine flower showing good evidence of the C. bellatum parent. From Mrs. Bruce and Miss Wrigley.

Oncidium tigrinum, Towneley Grove var.—From J. B. Adamson, Esq.

Cultural Certificate.

To Mr. A. Burns, for fine examples of Platyclinis uncata.

Groups, etc.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool staged a group to which a Large Silver Gilt Medal was awarded. Cypripediums in variety included C. Tom Worsley, C. Commodore, C. Forest King, C. Rothschildianum, C. Pyramus, C. Memoria F. M. Ogilvie, C. Alabaster, C. Mrs. F. Sander, C. Roundhead and C. Desdemona, Haddon House variety; with these were Brasso-Cattleya British Queen var. Leviathan; Sophro-Laelio-Cattleya Vulcan and Oncidium Forbesii.

Mrs. Bruce and Miss Wrigley, (gr. Mr. A. Burns), Bury, were awarded a Large Silver Medal for a group that contained Cypripedium Carola, C. Invincible, C. Archie Neill, C. Anna, C. Minos Youngii, C. Armistice II, C. Memoria F. M. Ogilvie, C. Obelisk and C. Morning, with Pleione humilis. Mr. John Evans, Colwyn Bay, staged Cymbidium Coningsbyanum and C. Schlegelii; Cypripedium Perseus var., and fine Dendrobium seedlings of the D. Lady Colman type. Messrs. A. J. Keeling and Sons, Bradford, staged Cypripedium Olympus var. The Chairman, C. Fantasiae, C. Macie and C. Pyramus var. Charm.

Mr. D. McLeod, Chorltom-cum-Hardy, staged Cypripediums in variety.

The Secretary regretted to have to record the death of Samuel Gratrix, Esq., one of the founders, a life-long supporter of the Society, and a most enthusiastic lover of Orchids.

Obituary.

Mrs. Arnold Hitchcock.—We very much regret to learn of the death of Mrs. Arnold Hitchcock, whose name has become familiar to Sweet Pea lovers through the variety that bears her name, and also in connection with her business association with Mr. Andrew Ireland. She died in Colchester Hospital quite recently, after a severe operation from which she never recovered consciousness. We offer our deepest sympathy to the family so suddenly bereaved.

Charles D. Inglis.—The seed trade and agriculture in the south-west of Scotland is poorer by the death of Mr. Charles D. Inglis, head of the firm of Messrs. J. Inglis and Son, seed merchants, Ayr, a business that was established by his father in 1832. Deceased, who was in his eighty-ninth year, was born and brought up at Stair House Farm, and for forty-eight years he acted as the firm's traveller, and being a rich humourist and good story-teller, he was very popular among the farmers. Outside of business Mr. Inglis's chief interest was in sport. There were few branches of sport that did not claim his allegiance in his earlier life. At one time he was an enthusiastic hunter and followed Lord Eglinton's pack, and for well over a quarter-of-a-century he was secretary of the Ayrshire Otter Hunt Club. He was a capital shot, a keen angler, curler and bowler, and won many trophies in coursing, his greatest achievement being the success of his dog Iron Duke in winning the Scarisbrook Cup at Southport in the 'seventies. Familiarly known as "Charlie" Inglis, he possessed a genial, warm-hearted disposition that made him a favourite in the wide circle in which he moved, and there was a large attendance of mourners at the funeral on Wednesday, February 6, when his remains were interred in Stair churchyard.

James Muir.—The death took place on Monday, February 4, in the Victoria Infirmary, Glasgow, of Mr. James Muir, head gardener at Crosby Tower, Troon. Deceased was a keen competitor at the leading shows throughout the country and scored notable successes at Glasgow and Edinburgh. He took a keen interest in the Sweet Pea trials, and his services were much sought after as a judge. Before going to Troon, Mr. Muir served in a similar capacity at the Tour, Kilmaurs. The funeral, which took place at Kilmarnock, was attended by a large number of old gardening friends who came from distant parts to pay a last tribute to the deceased, whose lovable and unassuming personality was greatly admired by all.

ANSWERS TO CORRESPONDENTS.

DAPHNE LEAVES DISCOLOURED.—*H. E. C.* No fungus was present on the Daphne leaves. The spots are entirely superficial. Some lesions surrounded by blackened tissue were to be seen and may be due to the punctures made by Aphides, of which there are at least two species known to attack the genus Daphne in this country.

MAKING A LAWN.—*M. Carter.* (1) Lime would aid the growth of Clover by helping to liberate phosphates and potash in the soil; but old grassland very often contains buried seeds of several species of Clover, and when the soil is dug up many of these seeds germinate and grow luxuriantly in the loosened earth. If lime was used in the soil it would be blamed for the Clover; but the latter will spring up from seeds whatever the nature of the soil, without any application of lime. A tennis court is no exception to any other lawn. (2) If the ground is inclined to produce moss it is a sign that the soil is acid, and if no lime were used, moss would appear on it in the course of two or three years. (3) Lime would improve the texture of a heavy, tenacious soil, and chalk broken to the size of Hazel nuts would be just as good as lime at the time of making the lawn. Dressings of sand on the surface afterwards greatly improve the texture, and these could be applied at intervals as found necessary. (4) Sulphate of ammonia extracts the moisture from the leaves of Clover and so kills them; but one dressing will not kill Trifolium repens (Creeping or White Clover). It is often necessary to apply an ounce of it to the square yard, at intervals of a fortnight, to sicken the Clover and kill the creeping stems. By this time the phosphates and potash will be exhausted, and it will be necessary to apply two ounces each of superphosphate of lime, and kainit, to the square yard, to support the grass. On no account use basic slag, because it favours the growth of Clover.

PLANTS FOR SHELTER FROM NORTH.—*C. D.* You do not state whether you require a hedge, or a screen, to shelter your ground, but, as it is not large, a hedge would be best, as shelter belts or screens of trees, unless they are broad, are apt to become open and draughty at the bottom. A Beech hedge should prove most suitable for your exposed position, as it does well in such situations, and in your type of soil. Beech makes an excellent close hedge, which would afford good shelter, as the old leaves are retained throughout the winter.

REMARKS.—In this department most lines have been somewhat shorter during the past week. Lilium longiflorum blooms in particular have been very scarce. Arums (Richardias) have been fairly plentiful. Good Daffodil blooms have been cleared very early each morning, only very small consignments of these having been received from the Channel Islands during the past week. Carnations are poor generally, first-quality blooms being in good demand, especially of Delight, Favourite, Eileen Lowe, Cupid, Spectrum, Mavis and Dora. Among Roses, Columbia and Richmond are the best at present; being new crop blooms, supplies are still very limited. In the French Department conditions have not improved, prices still remaining high for Paper White Narcissi, white Stock, Anemones and Violets. Nearly all the supplying districts have been affected by unfavourable weather conditions.

REMARKS.—There is a slight improvement in trade generally but the Market was glutted last week with Roscoff Cauliflowers.

GLASGOW.

Business in the cut flower market was quieter during the past week, and prices generally reflected an easier tendency. Early Tulips were very plentiful and on occasions the daily supplies exceeded the trade demand. William Pitt ranged in price from 1s. 2d. to 1s. 6d. for 6's; Bartigon and White Hawk, 1s. to 1s. 6d.; Le Notre, Cullinan and Couronne d'Or, 1s. to 1s. 3d.; Pink Blossom, 10d. to 1s. 2d.; Murillo and William Copland, 8d. to 1s. 2d.; Flamingo and Prosperity, 9d. to 1s.; Prince of Austria and White Diana, 8d. to 1s.; Thomas Moore, 7d. to 1s.; Mon. Tresor, 10d.; and Brilliant, 6d. to 10d. Daffodils are now arriving in greater quantities. Golden Spurs sold at 7d. to 1s. 4d. for 12's; Victoria, 1s. 6d.; ornatus, 7d. to 1s.; Soleil d'Or, 5d. to 8d.; and Narcissi, 2s. 6d. to 4s. per dozen bunches. Blue Irises were worth from 2s. 3d. to 2s. 6d; for 6's; loose Chrysanthemum blooms, 3s. to 5s. per dozen; Carnations, 2s. 6d. to 6s.; Pink Roses (Columbia), 14s.; Richmond, 10s.; Anemones, 2s.; Ranunculi, 2s. 6d.; Richardias, 7s. to 10s.; Snowdrops, 3d. and 4d. per bunch; Lilac, 2s. to 3s.; Lily-of-the-Valley, 1s. 6d. to 2s.; English Violets, 2s. per dozen bunches; French Violets, 3s. to 4s.; Asparagus, short, 10d. per bunch; medium, 1s. 6d.; trails, 2s. to 3s.; and Smilax, 1s. 6d. to 2s. 6d.

Pot plants were slow to move. Bay trees sold at 12s. each; Aralias, 2s. 6d.; Aucubas, 1s. 4d.; Dracaena, 1s. 6d. to 3s.; and Aspidistras, 1s. 2d. to 2s. 4d.

The fruit market displayed a firm tone. A cargo of Jaffa Oranges realised the following prices:—144's, 18s.; 128's, 15s. 6d. to 17s.; 240's, 18s.; 112's, 15s. to 16s.; 100's, 15s. 6d.; 120's, 16s.; and 80's, 14s. 6d. Quotations for Valencia Oranges were, 200's and 240's, 15s. 6d. to 22s.; 300's, 16s. 6d. to 20s.; 360's, 15s. 6d. to 18s. 6d.; 504's, 15s. 6d. to 18s.; 420's, 24s. 6d. to 26s.; large 420's, 28s. to 32s. Seville bitter Oranges sold at 20s. to 22s.; Murcia Lemons, 300's, 16s. 6d. to 23s. 6d.; 360's 16s. to 20s.; 504's, 12s. to 12s. 6d. Prices realised for American Apples were King of the Pippins, 28s. to 32s. per barrel; Albemarle, 26s. to 40s.; Greenings, 25s. to 30s.; Baldwins, 16s. to 22s. Pine Apples sold at 2s. 6d. to 3s. 6d. each; English-grown black Grapes, 2s. 6d. to 3s. 3d. per lb.; Cape Peaches, 4s. to 7s. per tray: and Plums, 4s. to 6s.

In the vegetable section, Cucumbers were cheaper at 1s. 6d. to 1s. 9d. each; while French Beans realised 7s. 6d. per box; Cauliflowers, 5s. to 8s. per crate of two dozen; Lettuce, 3s. 9d. per dozen; and Mushrooms, 2s. per lb.

GARDENING APPOINTMENT.

Mr. James A. Paice, for the past five-and-a-half years Gardener to C. E. GABAIN, Esq., J.P., Sunnyfields, Mill Hill, N.W.7, and previously nine years with the Rev. EDGAR STOGDON, Aldenham Vicarage, Watford, Hertfordshire, as Gardener to RICHARD D. HARDY, Esq., Copseham, Esher, Surrey. (Thanks for 2s. for the R.G.O.F. Box.—EDS.).

CATALOGUES RECEIVED.

CANNELL AND SONS, Loddon, Norfolk.—Flower and Vegetable Seeds, Bulbs, etc.

W. A. R. CLIFTON, Willingdon, Sussex.—Antirrhinums, Zonal Pelargoniums and Chrysanthemums.

C. L. CURTIS, Chatteris, Cambs.—Flower and Vegetable Seeds and Plants, Roses, Fruit Trees and Bushes, Ornamental Trees and Shrubs.

Bacteria as Indicaters of Soil Fertility.

The observant cultivator is well aware that the weeds growing in arable or grassland soils are faithful indicators of the general character and fertility of those soils. He knows that certain weeds, Nettles, for example, testify that the soil is well supplied with nitrogen, and that other weeds —plants of poverty—are a sure sign that the soil lacks some of the essential food materials on which fertility depends. It is possible, indeed, for the observant to go further and infer from the flora covering it whether a soil is an acid one or not. It has, however, long been evident that the micro-flora of the soil could, and it would, divulge much fuller information than that vouchsafed by weeds and such-like plants of larger growth. Micro-organisms—bacteria, for example—increase and multiply at a prodigious rate and therefore, were it known that three or four soil bacteria of well defined and easily recognised form are the habitués of fertile soil, it would be a matter merely of a day or two for anyone skilled in bacteriological technique—a fairly simple business—to decide whether a given soil is destined to prove fertile or infertile. For if the bacterial indicators of fertility refused to grow at their normal rate when planted therein, the soil in question could be classified among the infertile. A recent paper by H. J. Conn[*] adduces evidence which prompts the foregoing reflections. Dr. Conn has isolated a micro-organism which he names Bacterium globiformis, n. sp., from fertile soils. When "planted" in certain soils known to be infertile, B. globiformis refuses to grow. In other infertile soils, however, the micro-organism *will* grow, so that its fastidiousness is not so complete as it should be for it to qualify as a first-class indicator of soil fertility. Having regard, however, to the catholicity in taste of Bacterium globiformis in the matter of food, it is surprising that any soil should be found insufficient for its nutrition. For B. globiformis will absorb nitrogen in very varied form and carbon in a yet greater variety of compounds. It may, therefore, be that this bacterium is after all not so much an indicator of fertile soils as of acid soils, for as Dr. Conn has shown, B. globiformis cannot abide acidity. Here we are brought up against that greatest of all agricultural and horticultural puzzles—what does actually constitute soil fertility? The question seems so easy to answer when the happy grower has at his command a deep, black, well-drained loam, in which every crop easily achieves perfection. But it becomes hard to answer when the cultivator has spent three or four years trying to impart fertility to one of those unkindly, half sandy, half clayey soils which occur frequently in some of our southern counties. It is on such soils as these that the soil bacteriologist might concentrate, for, if soil bacteria are related to soil fertility, he might find that, as the years go on and the labour of improving fertility in one of these refractory soils receives a grudging response, the soil micro-flora might show a parallel development. Albeit a long, distant problem, it is an important one, for the areas of really fertile land, although vast, are by no means coterminous with the areas devoted to agriculture. In other words, many cultivators are, perforce, compelled to grow crops on land which falls short of high fertility. Any discovery which showed how these less fertile lands may be made more fertile, would confer much happiness on mankind.

Royal Horticultural Society's Next Meeting.—On Tuesday, February 26, the Annual Meeting of Fellows of the Royal Horticultural Society will be held in the New Hall. The exhibition will also be held in the New Hall and, of course, the Standing Committees will meet there. We learn that the restaurant will be in full working order on this occasion.

Appointments at Kew.—The following appointments at the Royal Botanic Gardens, Kew, have been made by the Minister of Agriculture and Fisheries:—Miss M. L. Green, B.A., F.L.S., to be an Assistant in the Herbarium, on the re-grading of her post as Sub-Assistant for the *Index Kewensis*; and Mr. E. M. Marsden-Jones, F.L.S., to be an Honorary Associate for Transplant and Breeding Experiments.

Langdale Valley.—Through the generosity of Professor G. M. Trevelyan, the National Trust has acquired about four hundred acres at the head of the famous Langdale Valley, in the Lake district. The property was purchased by Professor Trevelyan and presented to the Trust. It consists mainly of farmland, and includes Stool End Farm, Wall End Farm, and the Old Dungeon Ghyll Hotel. The property is not to become a public open space, but henceforth there will be no danger of it being "developed," and the retention of its natural beauty, unmarred by fresh buildings, is assured for all time.

Potato Wart Disease Immunity Trials, 1929.—The Ministry of Agriculture and Fisheries will continue during the coming season to test, at the Potato Testing Station of the National Institute of Agricultural Botany, at Ormskirk, Potatos and Potato seedlings as to their immunity from, or susceptibility to, Wart disease. Entry forms (No. 345 H.D.) and full particulars of the conditions governing the acceptance of Potatos for trial, may be obtained from the Ministry. Potatos are accepted from foreign growers on certain conditions set out in the rules, but no foreign variety will be formally "approved," and no certificate issued, until it is definitely introduced into commerce in Great Britain. The Ministry desires to encourage the breeding of new varieties of Potatos, and in order to provide information for breeders of seedlings. it is prepared to accept, up to March 1, not fewer than two tubers, and not more than five tubers, of any seedlings for testing in the laboratory, and to furnish a report on the results obtained without payment of a fee. A report of the result will usually be sent within five or six weeks of the receipt of tubers. These tests, however, will not be considered as forming part of the Immunity Trials proper, and will not be reckoned in the minimum period of two years referred to in the rules. The results of these tests will not be included in any report issued by the Ministry.

National Appeal on behalf of Studley College.—A national appeal for £20,000 has been launched by Lady Londonderry, as President of the Council, on behalf of the Studley Horticultural and Agricultural College for Women, Warwickshire. The lease of Studley Castle and the estate, comprising 340 acres, expires on July 1 next, and it is the desire of the Governors to exercise an option to purchase before that date. £10,000 is needed to meet the purchase price and to secure a promised grant from the Government of £5,000, while the remainder of the sum specified is required to repair and enlarge some of the existing farm buildings, and for other constructional purposes.

Fumigation with Hydrocyanic Acid Gas.—To those who are not conversant with the methods of using hydrocyanic acid gas for the fumigation of glasshouses, etc., we recommend the leaflet (No. 188), recently received by us from the Ministry of Agriculture and Fisheries, which deals with this subject in a brief and concise manner. In it is set forth information concerning the materials required, the doses suitable for different types of plants, and the best method of fumigating. It is a handy pamphlet for the gardener to have by him for reference purposes.

The Shortage of Biologists.—Much has been written in the daily press concerning the present shortage of biologists, and a review of the situation appears in the February issue of the *Journal* of the Ministry of Agriculture. In this, it is stated that there is a large and growing demand throughout the British Empire for men trained in the biological sciences, a demand which the Universities have not so far been able to satisfy, so that there is at present a dearth of qualified biologists. The reason given for this is that, from the elementary schools upwards to the Universities, there is a predominance of the physical over the biological sciences. The increased demand for qualified biologists is due to the fact that it is now recognised throughout the Empire that the services of the biologists are indispensable in connection with agriculture in all its branches, for the purposes of combating insect pests and fungus diseases of crops; breeding improved varieties and improving the yield and quality of crops; breeding improved races of livestock; increasing the output of meat and dairy produce; combating animal diseases; and preventing losses in the storage and transport of agricultural produce. It is stated that: "The prospects before able young biologists promise to be very bright for a long time to come, and it is important that parents and boys should recognise this fact." Salaries in Great Britain range from £300 to £800 per annum, with higher ones for directors of institutes; in the colonies they usually range from £500 to £950 per annum; while some of the highest appointments carry salaries of from £1,200 to £2,000 per annum. In this review of the situation sound advice is given regarding the means whereby training in biology may be acquired, and those who are interested and require enlightenment as to the various scholarships and grants available for would-be biologists are advised to obtain the pamphlet entitled *Notes on the Grants to Research Workers and Students*, published by H.M. Stationery Office, Adastral House, Kingsway, London, W.C.2, price 2d.

---

[*] "A type of Bacteria abundant in productive soils, but apparently lacking in certain soils of low productivity." *Technical Bulletin No.* 188, New York State Agricultural Experiment Station, Cornell University, July, 1928.

Memorial Medal awarded to Carnation Spectrum.—It is announced in the Annual Report of the American Carnation Society that, as a result of the poll of its members, the Marcellus Adams Patten Memorial Medal, conditions covering the award of which were announced in our issue for December 29, 1928 (p. 502), has been awarded to Carnation Spectrum. Betty Lou was a close second, and Winsome, third.

Land for Afforestation in North Wicklow.—In the *Economic Proceedings of the Royal Dublin Society*, Vol. II, No. 23, appears an interesting article dealing with the survey of the waste land of North County Wicklow suitable for afforestation, by S. Leonard, B.Sc. The objects of this survey were to find out what land, if any, is suitable for afforestation in North County Wicklow. No attempt was made to enquire into the feasibility of acquiring such land, as this would be the work of the Forestry Section. One general conclusion arrived at from this survey is—that the amount of land available for afforestation in Ireland is much less than is generally supposed. North County Wicklow may be taken as being fairly typical of the mountain districts in Ireland, and it has been found that land suited to afforestation and situated in blocks of a convenient size for management, totalled in all 11,900 acres. This is equal to six per cent. of the total area, or eleven per cent. of the waste land. The total of waste land in the north of County Wicklow amounts to 104,000 acres, of which the larger part is wild and exposed, with peaty or otherwise infertile soil. The portion dealt with in detail consists of land which it is considered would be favourable to tree growth. It has been shown that there are fourteen blocks, in most cases over three hundred acres in extent, which are at the present time in a state of unproductivity, or of very low agricultural value. It is urged that if this land was included in some scheme of afforestation, its value would be increased materially. There are, in addition, many small areas of waste land not dealt with specifically, which, if planted as shelter belts, would afford much-needed shelter for the agricultural land in the vicinity.

Carnations in Public Parks.—The Association of Parks and Botanic Gardens Superintendents (London Branch) will meet in the R.H.S. Lecture Hall, Vincent Square, on Tuesday, February 26, when Mr. Montagu C. Allwood will lecture on "Modern Carnations and their Use in the Public Parks," and will illustrate his lecture by lantern slides. The chair will be taken by Mr. A. J. Ashmore at 7 p.m. prompt.

Lecture by Mr. Cecil H. Hooper, F.L.S.—On the evening of February 11, Mr. Cecil H. Hooper, F.L.S., of the South-Eastern Agricultural Institute, Wye, read a paper entitled "Fruit Pollination in Relation to Commercial Fruit-growing," before members of the Royal Society of Arts, at the Society's headquarters in John Street, Adelphi, London, W.C.2. Mr. H. V. Taylor, Commissioner of Horticulture, Ministry of Agriculture, presided, and there was a large attendance of members and others, among them being several prominent horticulturists. Mr. Hooper dealt with his subject in a comprehensive manner, illustrating it with numerous excellent lantern slides. He touched upon the various methods of securing pollination employed by fruits of commercial importance, and then gave, in detail, the results that had been obtained in experiments connected with insect pollination, and self- and cross-fertilisation, of Apples, Pears, Plums, Cherries, etc., dealing with each in turn. Among points which Mr. Hooper emphasised in concluding his paper were: (1) If wild insects are not sufficient to effect good pollination of the crop, hive bees should be introduced to the plantation; (2) when planting an orchard, choose two or more varieties that flower at the same time, and, in the case of Cherries, avoid planting together varieties that are inter-sterile; and (3) where established plantations of fruit trees consist of only one variety, interplant or re-graft one tree in nine with another sort, in order to secure cross-pollination.

M. Firmin Lambeau.—One of the foremost amateur gardeners in Belgium, M. Firmin Lambeau, is keenly interested in all phases of gardening, but has become famous chiefly because of his fine and admirably cultivated collection of Orchids. He began to form this collection in 1900 by purchasing plants from M. Lucien Linden, of Brussels, whose nursery provided the foundation of so many excellent Belgian and French collections. In 1912, M. Lambeau transferred his Orchids from Square Vergote, Brussels, to his present estate at Chateau du Vogelsang, Woluwé, St. Pierre, in the suburbs of Brussels, where, near the Parc du Cinquantenaire, he has an extensive garden, beautifully laid out and planted with choice trees and shrubs, and comprehensive collections of hardy perennial and alpine plants, with a lake for aquatics. Here he has a fine range of fifteen glasshouses devoted to Orchids of all kinds, represented by the choicest hybrids. Two houses, each one hundred feet long, are devoted to Cypripediums that include most of the finest British and continental hybrids. On December 19 last, he exhibited a splendid group at Brussels (Fig. 66) and this contained Cypripedium Chrysostum var. H. G. Elwes, C. Gwen Hanner, Chadwar var., C. Imperator var. Vogelsang, C. Chardmoore var. Duchess of York, C. Crusader, C. Britain's Monarch, C. Corsair, Holford's variety, C. Cappa-Magna, C. Draco var. Vogelsang, C. Minotaur, Westonbirt variety, C. Nirvana, C. Primrose, C. The Warrior, and many other first-rate sorts, in addition to several of his own raising, notably C. Lucini var. dulcis, C. Memoria Lucini and C. Madame de Lazio var. Roi Albert. But Cypripediums are not the only claimants upon M. Lambeau's affections, as witness the fact that other kinds bear his name, *i.e.*, Odontioda Lambeauiana, Odontoglossum Lambeauianum, Miltonia Lambeauiana, Laelio-Cattleya Firmin, C. gigas alba var. Firmin Lambeau—which obtained a Gold Medal in London—while Miltonia Bleuana var. Reine Elizabeth was raised at the Chateau du Vogelsang. M. Lambeau has not been selfish in his affections for Orchids, for he has exhibited at most of the international exhibitions at St. Petersburg, Paris and Berlin, and has on four occasions, 1908, 1913, 1923 and 1928, won the Prix du Roi at the famous Ghent Floralies—a splendid record. As President of the Brussels Tribunal de Commerce, M. Lambeau is a busy man, therefore those who would find him among his Orchids should arrange their visit for a Saturday afternoon. But M. Lambeau is busy in other directions, encouraging the cultivation of Orchids in particular and of horticulture in general, for he is President of the Linnean Society of Brussels, of the Cercle des Orchidophiles Belges, of Les Amis du Pois de Senteur, and of the Brussels Horticultural Society, besides being a member of the Conseil Supérieur de l'Horticulture, the Council of the Brussels Botanic Gardens, and of the State School of Horticulture at Vilvorde. M. Lambeau recently lost, by death, his gardener, M. Ed. de Munter, who had been in charge of the garden for a long period; his place has been taken by M. Guillaume Heylen, who also has been in M. Lambeau's service many years. We congratulate M. Firmin Lambeau on his continued and active interest in horticultural matters, and find it a pleasure to present his portrait to our readers and illustrate a part of one of his displays of splendid Cypripediums.

M. FIRMIN LAMBEAU.

Retirement of Mr. J. Edmonds.—Mr. John Edmonds has just retired from the charge of Bestwood Gardens, Arnold, Nottinghamshire, after fifty-eight years' service under two Dukes of St. Albans. He is held in great respect by the family he has served so long and ably, and, although over eighty years of age, is very active, his only trouble of late years being deafness. Many years ago, in the days of Messrs. Goodacre and McIndoe, he was an exhibitor of fruit and groups of plants at the leading shows in the midlands and north of England. For many years he had charge of the woods, etc., at Bestwood, in addition to the gardens. His address now is Redhill Farm, Bestwood, Arnold, Nottinghamshire.

Flowering Plants of South Africa.—The plants described in the recently issued No. 31 of Vol. VIII (July, 1928), of *The Flowering Plants of South Africa* are:—Moraea Balenii (t. 301), Bonatea cassidea (t. 302), Aloe laxiflora (t. 303), Eulophia calanthoides (t. 304), Virgilia capensis (t. 305), Homeria Cookii (t. 306), Eulophia purpurascens (t. 307), Disperis Fanniniae (t. 308), Antholyza aethiopica (t. 309), and Holothrix Thodei (A) and H. confusa (B) (t. 310). Moraea Balenii is a handsome species from east Griqualand, whose yellow, Iris-like flowers resemble those of M. spathacea, from which it differs, however, in having narrower, whip-like leaves which are strongly convolute. In this country this species, together with other members of the genus, should succeed in a warm, well-drained border with a southern aspect, although it would be advisable to lift and store the corms for the winter. Of no especial attractiveness, although undoubtedly quaint in appearance, is Bonatea cassidea, of the Order Orchidaceae. The genus Bonatea is indigenous to Africa and contains about nineteen species, of which eight are found in extra-tropical South Africa. They are all tuberous-rooted, terrestrial herbs, with leafy stems ranging from six inches to three feet in height, terminated with racemes of green and white flowers. Bonatea cassidea is among the slenderest and smallest-flowered of the species. Aloe laxiflora (see *Gard. Chron.*, Vol. XXXIX, p. 130), is found in the Cape Province. It was first collected by Mr. F. G. Griffiths near Port Elizabeth. He sent living material of it to Kew, where it flowered in 1902. Its slender, tubular flowers are scarlet, yellow towards the tip, and are produced in lax racemes. Eulophia calanthoides (Orchidaceae, Tribe Vandeae), is found in Natal, Orange Free State and Transvaal, and is closely related to E. acuminata and E. Allisonii. The flowers are borne in loose racemes and are, according to the illustration, creamy-white, the lip being shaded at its base with purple. Virgilia capensis is an attractive, Leguminous, tall shrub or tree, abundant in the south-western districts of the Cape Province, where it is popularly known as Keurboom; its petioled flowers are more or less magenta-coloured, becoming paler with age, and are borne in lateral racemes. Homeria Cookii, Natural Order Iridaceae, is a greenish-yellow-flowered species closely allied to H. pallida; it was collected by Mr. F. J. Cook in Concordia Valley, Montagu Division, in October, 1922. Of dainty and attractive appearance is Eulophia purpurascens, found in Natal and the Cape Province, its rather small, purple flowers being produced in erect, terminal racemes, each containing eight or nine flowers. Disperis Fanniniae is another South African Orchid. It belongs to the Ophrydeae section, and is described as growing naturally in leafy-loam in the shade of other plants. It has large-hooded flowers, the hoods being white, spotted with purple, while the small lip is sharply reflexed. Antholyza aethiopica is well-known in English gardens as a coarse-growing member of the Order Iridaceae, which, in general appearance, closely resembles the Montbretia. It is too leafy and sparse in the production of its flowers ever to become popular. Holothrix Thodei and H. confusa are two other Orchids of the section Ophrydeae, of botanical, rather than garden interest, for their flowers are insignificant and by no means attractive.

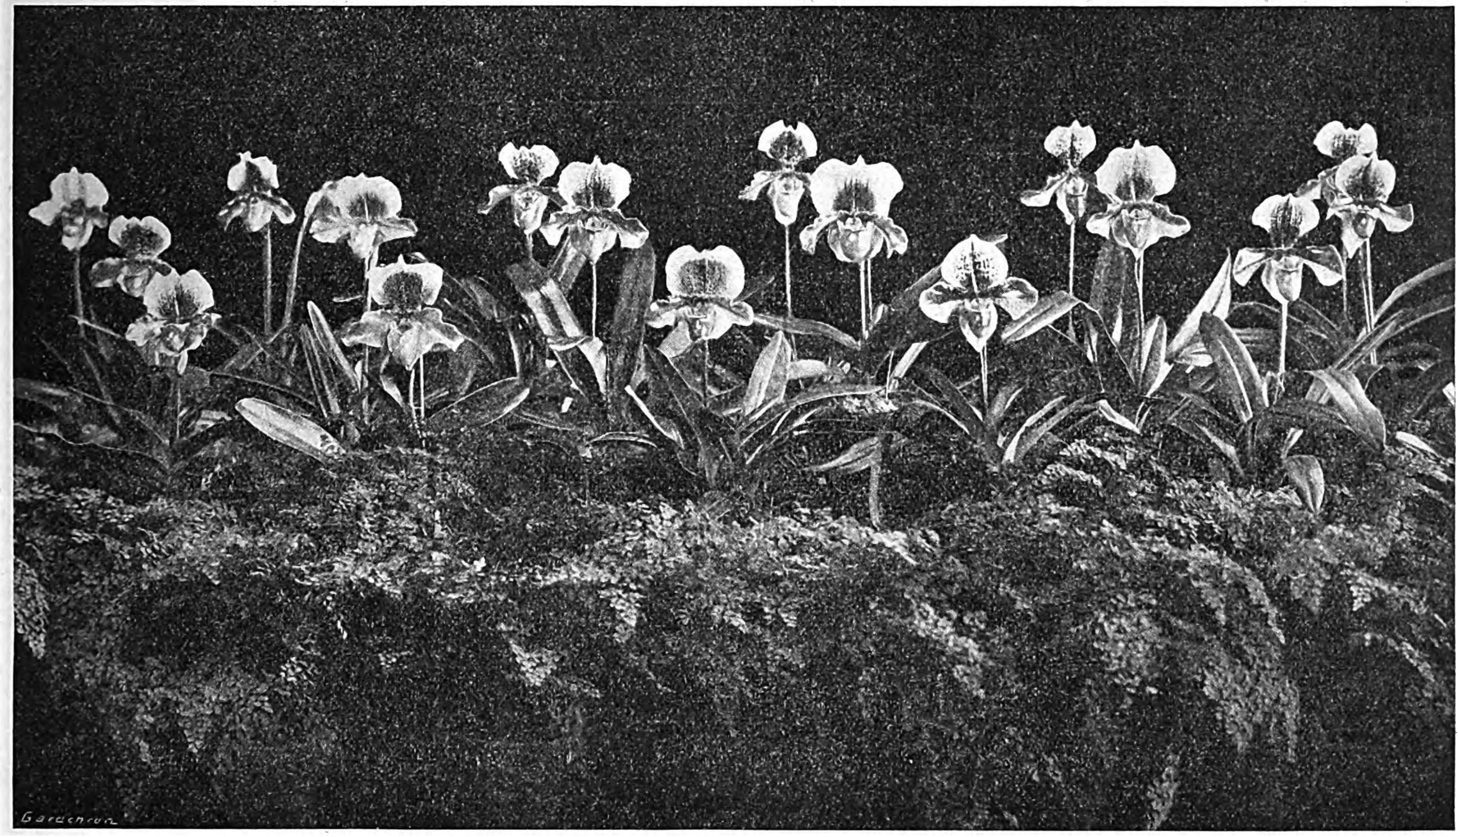

FIG. 66.—COLLECTION OF RARE HYBRID CYPRIPEDIUMS EXHIBITED IN BRUSSELS BY M. FIRMIN LAMBEAU.

Colonial Appointments. — The following appointments are announced as having been made by the Secretary of State for the Colonies: Mr. G. F. Clay, M.C., B.Sc. (Geneticist, Amani Institute), to be Senior Agricultural Officer, Uganda; Mr. D. Thornton, D.Sc., Mr. F. E. Buckley, A.R.C.S., Mr. K. D. R. Davis, B.A., and Mr. C. B. Taylor, Superintendents, Agricultural Department, Nigeria; Mr. T. H. Nicol, B.Sc., Agricultural Instructor, Sultan Idris College, Federated Malay States; Mr. J. L. Greig, B.Sc., Assistant Agriculturist, Federated Malay States; Mr. E. J. H. Corner, B.A., Assistant Director of Gardens, Straits Settlements; Mr. H. A. Pieris, Divisional Agricultural Officer, Ceylon; Mr. R. H. Cowan, Produce Inspector, Nigeria; Mr. R. M. Maynard, B.Sc., District Agricultural Officer, Tanganyika Territory; and Mr. H. B. Waters, B.A. (Deputy Assistant, Director of Agriculture, Nigeria), Deputy Director of Agriculture, Gold Coast. It is also announced that Mr. F. A. Stockdale, C.B.E., Director of Agriculture, Ceylon, has been appointed Assistant Agricultural Advisor to the Secretary of State for the Colonies.

A New Disease of Chrysanthemums.—At a meeting of the Glasgow and West of Scotland Horticultural Society, on Wednesday of the past week, Mr. Hugh MacSkimming, Auchenault Gardens, Helensburgh, described the symptoms of a disease which he had discovered in stocks of early- and late-flowering Chrysanthemums. When the plants are making splendid growth, the leaves curl close to the stem, then the plants shoot up and develop normal leaves, but the buds generally go blind. In the following year the stems become hard and the leaves small. As showing the injurious effect of this trouble he mentioned an instance of a batch of plants in their second year which hardly carried a flower. Affected plants have been sent to the East of Scotland Agricultural College at Edinburgh, but, so far, the staff has been unable to diagnose the disease, but it was suggested that it might be caused by an absence of potash, or by a Mosaic disease. In Mr. MacSkimming's opinion, the disease was likely to be a serious menace to the Chrysanthemum, as many of the stocks in the country had become infected before the trouble was recognised.

Venidium fastuosum.—The many readers who have written to us and to Mr. Hay, asking where seeds can be obtained of Venidium fastuosum—the subject of our coloured plate on February 2—will be glad to learn that Messrs. Ryder and Son, Ltd., St. Albans, secured a "fair quantity of seeds, which, unfortunately, arrived too late for inclusion in the 1929 catalogue." These seeds the St. Albans' firm is advertising in the present issue.

Appointments for the Ensuing Week. — Monday, February 25: East Anglian Institute of Agriculture's lecture; Birmingham and Midland Gardeners' Association's lecture. Tuesday, February 26: Royal Horticultural Society's Committees meet, and Annual Meeting; Royal West Renfrewshire Horticultural Society's meeting. Wednesday, February 27: Newcastle and District Horticultural Society's meeting. Friday, March 1: Manchester and North of England Orchid Society's exhibition; Dundee Horticultural Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Storing Apples in dry Sawdust.*—I have a dark closet in my house, or, rather, I live in a row with windows back and front. The house is four stories high, and the length from front to back is so great, that we have three rooms on a floor, the centre one dark. On the third storey the floors are plaster, and I find the temperature so even that I use it for a wine store in preference to the cellar, and have it fitted with bins. In this room I put some hampers of Apples (like Pearmain). I wanted one of the hampers, and turned the Apples on one of the bins, amongst the dry sawdust (Pine sawdust). A fortnight ago we looked at them, having used up the others gathered at the same time and from the same tree, all of which were much wrinkled, but on taking those off and from amongst the sawdust, I found them in a most beautiful condition; those covered with sawdust were as plump and fresh as when gathered, while those partially buried were only so to the extent covered with the sawdust, the upper portions being wrinkled. I am so pleased with the discovery that I shall pack them in bins next year, for I have no doubt they will keep in this way until next Christmas.—*Anon. Gard. Chron., February* 25, 1854.

Publications Received.—*Agricultural Entomology*, by D. H. Robinson, B.Sc., and S. G. Jary, B.A.; Messrs. Gerald Duckworth and Co., Ltd., 3, Henrietta Street, W.C.2., price 15/- net.—*Seed Trade Buyers' Guide*; The Seed World Chicago; price $1.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE, Manchester.

Trichopilias.—The Almond-scented Trichopilia fragrans thrives in the moist conditions of the cool house, in a position where all the available sunlight reaches the plants at this season; robust specimens often produce two crops of flowers during the year Flower scapes are now developing from the base of the pseudo-bulbs and, although this species and its variety nobilis require more moisture at the roots at this season than any of the other species generally cultivated, great care is needed when affording the water to prevent any coming in contact with the flower scapes, or they will decay quickly. This caution also applies to many of the other species when they reach this particular stage, notably, the free-flowering T. crispa; the brightly-coloured T. coccinea; the large-lipped, Hawthorn-scented T. suavis; the chaste T. Backhousiana, and the beautiful hybrid T. Gouldii; all of which are now in a partial-resting condition, in a light position at the cool end of the intermediate house, where they only require small quantities of water at the roots at fairly long intervals. Too much moisture at this stage will cause the roots to decay, and the black spot disease to develop on the pseudo-bulbs and foliage. Later in the season these Trichopilias will produce flower scapes from the bases of the pseudo-bulbs, and a gradually increased supply of water will be needed each time the compost becomes dry, applying it chiefly around the inner edge of the receptacle until the flower-stems are well advanced. Many kinds have decumbent flower spikes which are seen to advantage when the plants are suspended from the roof. After the flowering period growth becomes active, and fresh roots are produced as the young growths advance; at this stage any necessary repotting may be done, using well-drained pans and a rooting medium of three parts Osmunda-fibre and one part chopped Sphagnum-moss, adding broken charcoal to keep it open. Careful watering is necessary until the roots are well established in the new compost, after which ample supplies are required each time the soil appears fairly dry until growth is complete, when a less quantity will suffice. The plants thrive in a light position, but require shading from strong, direct sunshine, which soon affects the foliage, turning it a very unhealthy yellow.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Peaches.—The earliest Peach trees, on which the fruits are beginning to swell freely, should be syringed well with tepid water twice a day when the weather is fine, and once when it is cold and cloudy. As Peaches should receive no water at the roots during the flowering stage, a liberal supply should be given at a temperature of 70° to inside borders so soon as the fruits have attained the size of small Peas and the trees are forward enough for disbudding. This latter operation should be regulated by the vigour or weakness of the trees and the crops of fruits they are carrying. If the trees are in vigorous growth, the young shoots may be removed with a liberal hand, but not to such an extent that growth will be checked, while weak trees should be encouraged to make free growth by delaying the disbudding. Where fruits have set in clusters of two and three, they should be thinned to one, naturally the best, and if there is a good set, all the fruits may be removed from the undersides of the shoots, as those on the upper sides will have the full benefit of the sun and will colour better. Vigorous young trees do not require feeding, in fact they may be seriously injured if stimulants are given at this stage, but old trees which set fruits from every flower and carry heavy crops annually, derive great benefit from applications of diluted liquid manure. If green fly appears, fumigate the house without delay, on a calm, dull afternoon, when the foliage is quite dry. The later trees, which are to provide a succession of fruits to the early ones, and which were started at the beginning of the year, should be kept well supplied with atmospheric moisture, according to outside climatic conditions. Syringing once a day is beneficial, but the old method of keeping the trees constantly moist is detrimental. Green fly should be checked by one or two moderate fumigations as the trees approach the flowering stage, otherwise this pest will mar the trees, and possibly ruin the crop. A temperature of 48° to 50° at night, and 60° to 65° by day from fire heat, should ensure the production of perfect flowers, which should set freely enough, provided the pipes are kept warm and the house ventilated carefully. Although Peaches set freely on walls without the aid of artificial heat, they always do best when bright sun raises the temperature to 70° to 80°, and the atmosphere is moderately charged with moisture, therefore we should endeavour to produce such conditions in our forcing houses by maintaining a brisk, buoyant atmosphere, admitting plenty of fresh air.

Late Peaches.—Late houses, in which the best mid-season and late varieties of Peaches are allowed to come on slowly, should have abundance of air admitted whenever the weather is favourable, not only by day, but also at night. Watering should not be neglected, especially where all the roots are inside and the drainage is good. When retarding can be practised no longer, and the trees begin to open their flowers, syringing on fine, bright days will do them no harm, while fumigation should not be neglected. Fire-heat may be employed to maintain a temperature of 45° to 50° by night, and 60° to 65° by day, to facilitate the setting of the fruits.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Delphiniums.—Few herbaceous plants give so much satisfaction as do Delphiniums. There are many species in cultivation, some being of value for the herbaceous border, but the most important are the tall hybrids in an endless number of varieties and a wide range of colours, from pure white to the palest shades of lavender, and in every shade of blue. The height of the plants and the size of the individual flowers vary considerably. Delphiniums thrive in almost any soil or position, but to obtain the best results they should be afforded generous treatment. The site for them should be trenched deeply, a plentiful supply of well-decayed cow manure being incorporated in the soil as the work proceeds. The choice of position is an important matter; protection from cold, cutting winds in spring should be afforded, as the tender growths are easily damaged. Such a position can usually be secured with a background of shrubs, which enhances the charm of the plants when in bloom. Delphiniums do not resent a certain amount of shade from the midday sun in the south, but should not be grown actually under, or too close to, trees. They should be replanted every three or four years in early spring, as growth commences. Better still, where time permits, a fresh stock should be propagated from single eyes, and now is a good time to carry out this operation. Late summer, after the flowering period, and when secondary growths are appearing, will also be found a suitable time for dividing and replanting. Late-autumn or winter-planting is not advisable, as plants so treated never seem to become established. Delphiniums are most accommodating plants, and can be made to continue in bloom for several months by removing the finished spikes periodically. To secure flowers in late autumn, the first flower spikes should be removed before the seeds have set. Another method is to cut the entire plant to the ground when it has finished flowering, when a supply of young growths will spring from the base; but if this plan is adopted, generous treatment in mulching and watering must be given or the plants will soon become exhausted. On hot, sandy soils, it is always advisable to apply a mulch of well decayed leaf-mould or humus, to keep the ground cool and moist.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Lecturer in Horticulture, Reading University.

Old Apple and Pear Trees.—Trees which are for the most part sound, *i.e.*, with good stems and branches, yet which bear inferior fruits, make suitable subjects for rejuvenation by top-grafting with suitable kinds. These trees should now be headed back to within a foot or so from where it is intended to graft; this will allow for a further cutting back to fresh wood when grafting time arrives. The scions for this purpose should be secured while the buds are still dormant. They should be partly buried in moist soil or sand in some shady position, or on the north side of a wall, as success in grafting largely depends in keeping the scions plump and dormant until required. Trees that are still bearing useful crops may be improved, and, indeed, made profitable, by a judicious thinning of the branches. Where this operation has been neglected for some years, the thinning should be spread over two or three years, to lessen the risk of checking the tree, and avoid the production of sappy shoots. Crowded branches, and those which cross others, should be cut clean out at the base, the cut surface being trimmed with a sharp knife and covered with paint, grey-green for preference. The trees should then receive a good cleansing wash, such as caustic alkali, if they are infested with lichen or mosses. If they are comparatively clean, a good lime-wash is to be preferred. This wash should be made from the best lime shell, 25 lbs. to 28 lbs. to fifteen gallons of water, and put on, while hot, with a very coarse nozzle. The lime shells should be placed in a wooden tub, capable of holding fifteen gallons, and sprinkled with just enough water to make it turn to powder. If the tub is covered with a sack, the operation will be hastened. The water should then be added to the powder, five gallons at a time, and stirred briskly and continuously. When transferring the solution to the sprayer, run it through coarse sacking to remove any grit which may choke the nozzle. Apply it to the trees at once, paying particular attention to the twigs where the eggs of aphis and other insects are deposited.

American Gooseberry Mildew.—Where there is any suspicion of this disease the Gooseberry bushes should be sprayed with a dilute lime-sulphur wash, about one in twenty, making certain that every portion of the wood is thoroughly wetted with the wash.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hatfield, Hertfordshire.

Clerodendrons.—Specimen plants of Clerodendron Thomsonae and C. splendens speciosissima will now require attention with regard to top-dressing with fresh rooting material. The old soil should be removed carefully with a pointed stick, care being taken not to injure the roots, and before applying the new compost, see that the drainage is in perfect order. The top-dressing material which, when applied, should be made fairly firm, may consist of good turfy loam, leaf-mould, and a little peat, with a good quantity of silver sand added. Young plants of C. Thomsonae that were propagated last spring should now be transferred to larger receptacles, and if their growths are trained over wire frames they make attractive pot plants either for the dwelling house or the conservatory, for they remain in flower over a long period

Bouvardias.—Where it is desired to increase the stock of Bouvardias, some of the old stock plants should be pruned lightly and afforded a temperature of 55° to 60°, when they will soon start into growth, the young shoots being secured as cuttings when from three to four inches in length, placing them near the margins of small pots filled with an open compost, in a close frame. Bouvardia cuttings are somewhat slow-rooting, but if treated in this way no difficulty should be experienced. They are increased readily by means of root cuttings. For this purpose some of the strongest plants should be shaken out of their pots, the thickest roots being secured and cut into pieces about one inch in length, which should then be dibbled into pots of sandy soil and placed in a close frame. There are certain varieties which do not come true from root cuttings, but in most instances a good proportion of plants true to type is secured. White fly is a troublesome pest of Bouvardias, and unless kept in check, success in the cultivation of these subjects cannot be assured.

Coleuses.—Seeds of Coleus may be sown now, while cuttings from well tried varieties that have been kept as stock plants through the winter may also be inserted. Coleus cuttings root very quickly in a warm atmosphere if lightly shaded. Coleuses are rapid growers, therefore, to obtain the best results, they should never be allowed to become pot-bound until they are in their final pots, at which stage liquid manure should be applied frequently.

Gardenias.—Specimen Gardenias that are commencing to bloom should have all side-growths removed, and should be fed liberally with liquid manure. Gardenias are gross feeders, and to obtain flowers of good quality frequent applications of manure in some form are necessary. Young plants should be potted on to provide a succession of blooms, while cuttings may be inserted to secure a stock of young plants. The cuttings, if possible, should be of good, stout, basal growths, about three to four inches in length. They should be inserted around the sides of small pots filled with a mixture of loam, peat and sharp sand, and placed in a propagating frame.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Early Potatos.—If narrow borders along the fronts of glasshouses are available, these form ideal situations in which to grow early Potatos. The borders need to be only twenty inches wide, the Potato sets being planted six to eight inches from the wall. Pieces of tiffany along the front of the borders will protect the Potatos from slight frosts. Potatos grown in situations such as these will produce tubers quite early in the season. More "seed" Potatos should be placed in boxes for sprouting, in a house a few degrees warmer than the store-room.

Lettuces.—Plants that have been wintered in the seed-bed will now be ready for planting out in warm borders with a south aspect. They do not require so much room between the lines as the summer varieties, as they do not attain such large dimensions.

Peas.—More Pea seeds may be sown in a south border. Fork the ground lightly on a dry, sunny day, so that the surface will dry; sowings should now be made every week to maintain a successional supply of Peas. Later and taller varieties of Peas should be sown in trenches, into the bottom of which plenty of manure should be placed.

Spinach.—So soon as the ground is in suitable condition, seeds of the round-leaved Victoria variety may be sown in a south border. The surface of the Spinach Beet bed should be hoed or loosened with a cultivator, as this vegetable will soon be restarting into growth.

Parsnips.—Some growers prefer to sow this crop in February, others in March, but much depends on the type of ground. If the ground is light, Parsnip seeds may be sown now with every prospect of good germination. The ground cannot be cultivated too much for Parsnips; it should be forked deeply and the surface broken down to a fine tilth previous to sowing the seeds.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemount, Monkton, Ayrshire.

General Work.—Now that pruning is finished and most of the prunings and other vegetable refuse have been collected, an attempt should be made during frosty or wet weather to turn such into useful material for returning to the ground in due course. All vegetable refuse should be placed in a heap where it will not be too much in evidence, and allowed to rot; it makes a first-class manure for mixing with the soil or applying as a top-dressing. All woody matter, diseased vegetables, or those affected by club root, maggot or such like, should be burned. This is quite a simple process if a few pieces of heavy wood, or tree roots, can be secured. Place them in a circle, touching each other, and kindle a fire in the centre, feeding it until a good body of glowing ash has resulted; this will kindle the circle of wood and, if covered in carefully, will burn for days, or even weeks, provided the heat is not allowed to escape. Cover any holes which may develop and when it has burned out cover the ash or remove it to a shed, where it can be kept dry. A good sprinkling of this ash, if applied dry, is of great assistance in preparing the ground for small seeds; it may be used as a top-dressing in the fruit quarters, and is useful as a dressing for Potato ground. It has a beneficial effect on heavy ground, and is a valuable source of potash.

Maincrop Onions.—This crop should be sown so soon as the soil is in a suitable condition, that is, when it is dry on the surface. If the Onion bulbs are to keep well, the whole supply of food should be in the ground prior to sowing the seeds, whether it is from natural or artificial manure. A good tilth should be secured, and the soil firmed before sowing the seeds in shallow drills one foot apart. The seeds should be sown very thinly, a quarter-of-an-ounce to thirty yards being ample; they should be covered with a little fine soil, if the land is of a clayey nature, or the natural soil if otherwise, and the rows trodden to complete the operation. If sown in this way, no thinning of the seedlings will be necessary, therefore the danger of attack by the Onion fly will be lessened.

Autumn-sown Sweet Peas.—These have been making rather weakly growth owing to lack of light, but should soon respond to the lengthening of the days and increase of sunshine, if we are so favoured. Keep them near the glass, whether in frames or a cool house, and provide them with support in the form of short twigs, so that good, sturdy plants may be had either for flowering in pots or for planting out-of-doors.

Hydrangeas.—These should now be taken from the frames where they have been wintered and placed in a cool house. Remove any loose surface soil and top-dress them with some good, rich compost. In a few weeks they may be placed in a moderate temperature to force them into growth. As growth advances, feed them once or twice a week with liquid manure, or give dressings of a good fertiliser, such as Clay's, at intervals.

Chrysanthemums.—The cuttings intended to provide plants for late-flowering, if rooted in boxes, should not be allowed to remain crowded. Pot them singly and keep them in close and warm conditions for a few days, afterwards cooling them off gradually to normal conditions. I prefer to put them singly into small two-inch pots at the present time, potting them on into larger receptacles as they require it, and I find I get as many flowers from one, as from three plants grown together in a pot, except in the case of varieties which do not "break" readily, and most large-flowered Singles. The compost should be light and rich, consisting of two-parts loam, one part leaf-soil, and one part well decayed horse or cow manure, with plenty of sand, and a little powdered charcoal and lime-rubble added. Do not pot them too firmly and after potting water them gently.

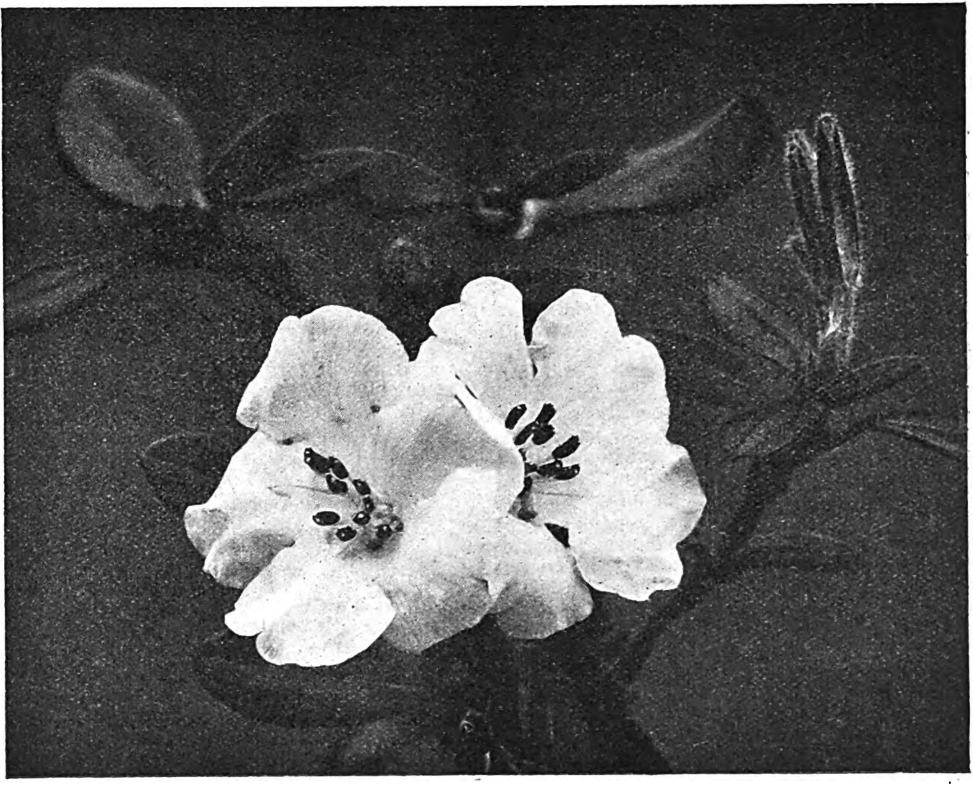

FIG. 67.—RHODODENDRON SP., K.W. 6,273.

R.H.S. Award of Merit, February 12. Flowers milky-white. Shown by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Southampton. (see p. 128.)

ALPINE GARDEN.

MOLTKIA PETRAEA.

Also known as Lithospermum petraea, this is a charming little shrub for a really hot, sunny place in the rock garden. It comes from the Grecian Alps and, although introduced over a century ago, has never been common in gardens. This is probably due to the fact that it is not so hardy as one would wish it to be. But dampness is more detrimental to its welfare than frost, and it will often live for many years, even where the climate is anything but genial, provided it has a roothold in poor, rocky soil—thus ensuring sharp drainage—and full sun.

M. petraea makes a neat bush of from one to two feet in height, its grey-green, narrow leaves, which are evergreen, suggesting a small Lavender bush. Towards the end of May, the tips of the shoots become studded with rosy-purple buds, these developing into clusters of tubular flowers in a pleasing shade of violet. As these blooms open in succession, the period of blossoming lasts for several weeks. Propagation by cuttings is not difficult, and as growth is generally slow, and the permanence of old plants by no means assured, it is well always to have a few young ones to hand. *J.*

SEDUM MIDDENDORFFIANUM.

Among the Sedums which are sufficiently distinct to merit being planted freely on the rock garden is S. Middendorffianum, whose chief charm lies in the rich colouring of its foliage. although when in blossom it is also very effective, for the flowers, produced in flattened terminal clusters during July, are bright golden-yellow, with dark purple anthers.

The late Mr. Reginald Farrer, in his *English Rock Garden,* did not do justice to this Sedum when he described it as "lying about on weakly shoots of six inches or so," for in my experience of it, the growths are closely packed, and form bushy clumps, never sprawling or untidy in appearance, and when a number of plants are grouped in a bed, in the hottest and sunniest position, in soil that is light and not too rich, they soon grow together and form a close carpet. which in summer is converted into a sheet of gold.

But, as stated previously, it is not the flowers which form the chief charm of this Stonecrop, but the foliage, which, provided the plants are grown in a warm position, and in soil not so rich as to encourage vigorous growth, is always tinged with bronze, the colouring being accentuated as the season advances until, by autumn, the plants are burnished masses. Some authorities give an autumn-colouring variety, under the name S. M. var. hybridus, although it is doubtful whether this distinction is justified, as the colouring seems to be a fairly general character, being evident also in the variety minor, which is dwarfer than the type in all its parts.

PUTORIA CALABRICA.

Although, perhaps, this comparatively rare subject is best grown in the alpine house, it will, if planted in suitable conditions, last for a number of years in the open rock garden and form a bushy little plant some nine or ten inches in height.

And it is certainly worth while endeavouring to coax it into establishing itself, for it is a plant of rare charm ; it should be planted in a warm and sheltered position—it comes from the sunny cliffs of Spain and Greece—in light loam, and is most likely to succeed if planted in a horizontal crevice of a cliff, with a slightly projecting rock above to shed off the rain. In winter, the shelter afforded by a sheet of glass placed above it will also be beneficial, as it is winter wetness which is chiefly responsible for its decease.

Its branched growths are covered with soft down and furnished with narrow, shining leaves. The flowers are produced intermittently, but never very profusely, throughout the summer months ; they are small, wax-like trumpets of a clear rosy-pink, and in appearance are very similar to those of Daphnes, although they lack the fragrance associated with the latter genus, in fact, they are—an unfortunate trait in blooms of otherwise such excellent charm—of a rather unpleasant odour, a fact indicated by the generic name, the root of which is *putor*, meaning, a strong smell. However, this fact alone is not sufficient to justify its banishment from the garden.

If P. calabrica fails in the open garden—failures with it are more numerous than successes—then it might be included in the alpine house collection, for plants may be secured by inserting cuttings in pure sand in a cold frame during the summer. It is not among the easiest of subjects to propagate, but a reasonable proportion of the cuttings should root if tended carefully and not kept too moist, and these, if potted in a light and open compost, may be wintered in a cold frame or alpine house.

It is stated that Putoria calabrica produces black berries in succession to its beautiful flowers, but I do not know if this is true of it in this country. *W.*

OURISIA MACROPHYLLA.

To my surprise, I find that Farrer dismissed this charming plant with a few words, for I looked it up in his *English Rock Garden,* anticipating a fascinating pen-picture of it, but he had very little to say about it. It was such a handsome subject in my sandstone rock garden last year that I longed for the genius of a Farrer or an A. T. Johnson to fittingly describe it.

Like many another graceful plant now becoming established in our gardens, it is a New Zealander and apparently quite hardy, having withstood 23° in a north-facing rockery for two years in succession.

O. macrophylla is slightly rhizomatous, although not so markedly so as O. coccinea, and forms spreading clumps and mats of handsome, rather hairy leaves, some two to two-and-a-half inches long ; these are of a darkish green, with effective veins and blotches of deep purple, ovate in shape, and decidedly toothed. Rather late in the summer, the six- to nine-inch stems appear, bearing, sometimes in whorls, although more often in a few-flowered umbel, the handsome flowers, almost reminiscent of a Pentstemon, but not quite so tubular, and with a wider mouth, and a pendant lower lip ; the whole flower is white, with beautiful, deep violet veins and blotches.

In Bailey's *Cyclopedia of Horticulture* it is described as attaining two feet in height, with leaves up to five inches in length ; it may possibly achieve these dimensions in its native habitat, but in this country I have never seen it exceed the size I have mentioned, and so I hope it will remain, for I can quite imagine that, despite its present beauty, which no one could possibly deny, it might easily gather coarseness with size.

It is best planted in half-shade, in the shelter of a rock, in deep, cool soil with plenty of broken stones around the crown. Thus situated it will thrive and increase in size and beauty from year to year. Propagation is readily effected by division and seeds. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

BULB GARDEN.

LILIUM PHILIPPINENSE VAR. FORMOSANUM.

The illustrations of this fine Lily in a recent issue (Fig. 32, 33 and 34 ; pp. 62, 63 and 64), draw attention to its noble proportions. There are two forms in cultivation. The first I grew was the dwarfer form and quicker-growing, flowering in fifteen months from seed-sowing, or earlier, when about nine inches high. In later years, the type figured has become more general in cultivation. It possesses a remarkable characteristic, *i.e.*, its slow growth. I know of no other Lily that cannot be brought into active growth under glass, but this variety will not be hastened. I was at Lochinch in July of last year and saw colonies of Lilium philippinense var. formosanum not more than two feet high, with thick stems and luxuriant foliage, in perfect health. Yet it was not until November they flowered. If it is grown under glass all the summer it will not be hurried. L. auratum and L. regale will grow inches in a week, but with L. philippinense var. formosanum a few inches in a month is more the pace. Is it because it is found at high altitudes ? As a foliage plant it is strikingly beautiful, and planted out in a cool house greatly rewards its owner with magnificent heads of blooms in the autumn.

I spent a glorious three days in late July of last year at Monreith, Castle Kennedy and Logan, and was fortunate to find the owners in every case at home. I deemed myself very lucky, and wish I could write of the charm of Monreith and its cultured owner, of the glories of Lochinch, and of the bewildering multitude of interesting plants at Logan. I doubt if three such outstanding owners and gardens could be found in any other similar area in the British Isles. *R. W. Wallace.*

HARDY FLOWER BORDER.

MONARDAS.

The Monardas comprise a small family of handsome, herbaceous perennials, well suited for planting in herbaceous borders or for naturalising in the wild garden, and are among the easiest of hardy plants to grow. Natives of North America, the various species, and especially the scarlet-flowered Monarda didyma, brighten the woodlands and stream margins of their native land during the summer and autumn ; M. didyma is, in fact, one of the brightest-flowered among the many attractive wild plants of North America. Although so small a genus, the nomenclature of the Monardas is very confused, chiefly on account of the great variability of M. fistulosa, which has numerous forms, each of which has been raised by various botanists to specific rank.

The most popular and best-known species is, of course, M. didyma, commonly known as the Oswego Tea, a name derived from the fact that its foliage has, at times, been used as a substitute for Tea. This species is also often erroneously termed the Bergamot.

It is a free-growing plant, very effective when massed, and growing to about three feet high, its growths, clothed with aromatic foliage, being terminated during July, August and September with dense whorls of gaping, deep red flowers. Although in itself well worth growing, the type has been superseded in gardens by colour forms with flowers of even greater brilliance, foremost among them being the variety Cambridge Scarlet, equally as vigorous and free in growth, but with flowers of a rich and vivid scarlet. This form is now extremely popular and is firmly established in gardens. Then there is the variety Sunset, of comparatively recent introduction and not, as yet, very widely grown, which has closely-packed heads of rich, reddish-purple blooms. The variety salmonea has large heads of bright flowers in a delicate shade of salmon-pink, and seems better suited for growing in moist places than the others, being especially attractive if planted in masses on the margins of ponds ; like the other Monardas, the best display is secured from this variety if it is lifted and replanted every three years or so, as when so treated it remains fresh and vigorous. The replanting should be done, preferably, during the early spring, as autumn planted clumps do not always establish themselves successfully. There is also a desirable white form, M. d. alba, which might well be given a place in the herbaceous border, if space permits.

Monarda fistulosa, the Wild Bergamot, is, perhaps, best suited for naturalising in the wild garden, unless borders of large dimensions have to be filled. It is, as stated previously, a very variable plant, the colour forms ranging from white, through pink, rose and lilac, to crimson and deep purple, but none is comparable to M. didyma in brilliance of colouring. M. fistulosa will, according to the position afforded it, attain a height of from two feet to five feet, its leaves, borne on angled stems which are typical of the genus, being of firmer texture than those of M. didyma, while the flowers are not produced so freely and are, in the type, purple in colouring. Among its many forms, mention may be made of variety purpurea, with smaller blooms than those of the type, of a rich purplish-crimson; var. rubra, rich rosy-red or crimson; var. media, deep purple; and var. mollis, the flowers of which vary from flesh-pink to lilac.

M. Bradburiana is described as a distinct species by several authorities, its chief distinguishing character being in its flowers, which are light purple, the middle lobe of the lip, which is considerably larger than the lateral ones, being spotted with deeper purple. This is, according to Bailey (*Cyclopedia of Horticulture*), the M. fistulosa flore maculata of *Bot. Mag.*, t, 3,310. It is dwarfer than the preceding species, and is better adapted for growing in moderately dry situations.

Another distinct species, which is sometimes offered by nurserymen, is M. Russelliana, a free-growing sort with pale, pinkish-mauve flowers, veined with purple, and purplish bracts; like the other species, it flowers in late summer and autumn.

The Monardas present no cultural difficulties, for they are easy to establish in any good garden soil, are readily increased by division, and are quite hardy, the fact that they flower late in the season enhancing their value as garden subjects considerably. *M. W.*

INDOOR PLANTS.

APHELANDRA AURANTIACA ROEZLII.

This is, without doubt, the most handsome of all the Aphelandras. The flowers are of a vivid orange-scarlet, borne in terminal, four-sided spikes. The foliage is rather curiously twisted and has wide lines of a silvery hue running through the whole length of their surface, which gives the plant a rather attractive appearance.

Aphelandra aurantiaca Roezlii is a native of Mexico, and in this country requires a moist, stove atmosphere, while in active growth, but should be removed to a somewhat lower temperature when commencing to flower; this will considerably lengthen their period of flowering. Cuttings of fully or half-ripened wood should be taken during the spring and rooted in a medium of loam, leaf-soil and peat, with plenty of coarse silver sand added. If placed in small sixty-sized pots in a propagating pit or case where a brisk bottom heat can be maintained, the cuttings should soon root, and when sufficiently rooted should be potted on into fifty-four-sized pots previous to potting them into six-inch pots in which to flower. The compost should consist of equal parts of fibrous loam, leaf-soil and peat, with a liberal proportion of coarse silver sand added to keep the whole open. They should be grown on without being stopped; by so doing the flower spikes will be much finer and the plants should come into flower much earlier than if they had been stopped.

During the growing season, much benefit will be derived from frequent syringings of tepid water, with occasional applications of weak liquid manure, and doses of weak soot-water about once a fortnight; feeding should be discontinued when the flower spikes show signs of expanding.

By keeping a few of the old stock plants over the winter, fresh batches of cuttings may be struck each year; these will be found more satisfactory than old plants which have been grown on. After flowering, stock plants should be pruned back lightly and given a slight rest until March, when the heat and water supply may be increased gradually to induce them to break into growth and so produce cuttings. *E. Baker, Garston Manor Gardens, near Watford, Herts.*

MUSA ENSETE.

The Abyssinian Banana (Musa Ensete) is found on the mountains of Abyssinia. It is the largest known Banana and is used to a considerable extent for ornamental planting in sub-tropical countries.

The plant is of great importance for food purposes as a vegetable in the damp valleys of Abyssinia. The flower-stalk, before it has emerged from the top of the trunk, is the portion eaten, and it is stated that, when cooked, it possesses a Cabbage-like flavour.

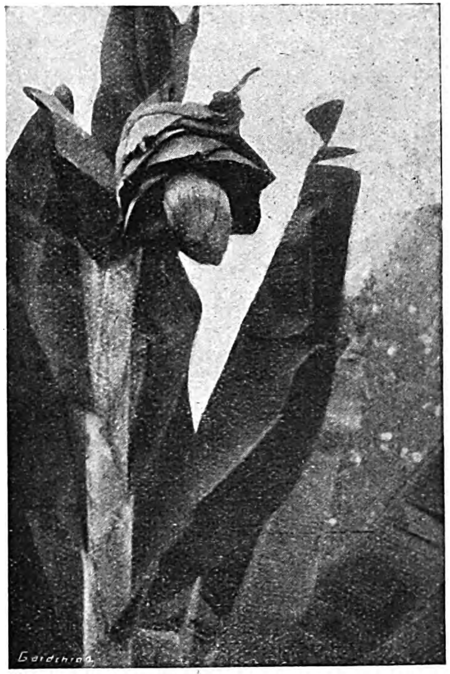

FIG. 68.—MUSA ENSETE FLOWERS SIX DAYS OLD.

Unlike other members of the Musa family it produces no suckers and perishes after fruiting, therefore it is necessary to propagate it from seeds.

The leaves are bright green, with a bright crimson midrib, and the flowers are arranged in clusters of twenty; the perianth is from one-and-a-half-inch to two inches long. The seeds, one to four in number, are an inch broad, black and glossy; they are strung into necklaces by the natives of Abyssinia.

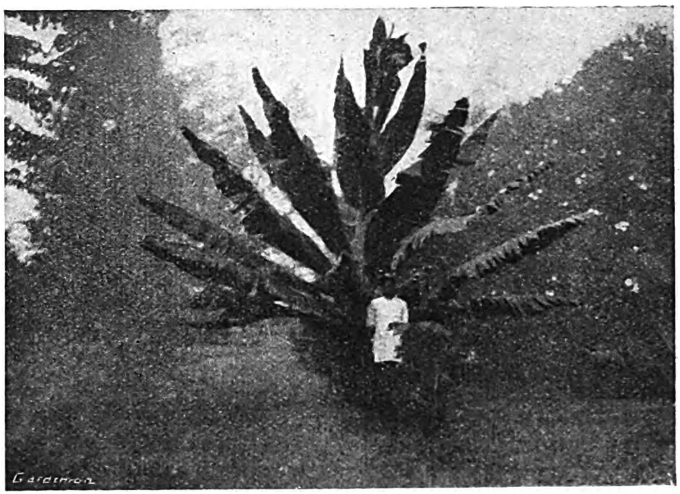

FIG. 69.—MUSA ENSETE IN FLOWER.

According to Sir Joseph Hooker, a few seeds of Musa Ensete ripened in the Palm House at Kew in 1860; the female flowers were specially fertilised with pollen taken from the scarcely opened male flowers.

The accompanying photographs (Figs. 68 and 69) represent a plant eighteen months old. It was sixteen feet high and the flower-stalk eight feet long. The basal leaves were seven feet long and two feet six inches broad, and the inflorescence, consisting of seven "hands," with sixteen fruits to each hand, was two feet six inches long. *F. S., Banfield, Taiping.*

FLOWER GARDEN.

PORTULACAS.

Those who are familiar with the distinct characteristics and appreciate the beauty of these old-fashioned, brilliantly-coloured annuals, have probably noted with interest that they appear to be enjoying a rising degree of popularity and, although one would not advocate the growing of them on a very large scale, they are well worthy of consideration, especially for exposed and dry positions. They can also compete with some of the more aristocratic bedding subjects, however, and visitors to public gardens are not slow in recognising the merits of the genus. They were used on a fairly large scale as a groundwork in bedding schemes on the sea front at Brighton last year with excellent results, and the effect produced was both beautiful and uncommon.

Essentially plants of the sun, requiring warmth and sunlight for their full development, the Portulacas flower most freely in hot, dry summers, but on light, warm soils they never fail to produce beautiful effects. They are all dense in growth and quickly form a bright, green carpet, which, in sunny weather, becomes thickly studded with richly-coloured flowers in various shades. Double and single forms are obtainable, and each type is so beautiful that both may be grown with advantage.

Portulacas do not become exhausted from flowering as in the case of many other subjects, and, however early they come into flower in the summer, they may be depended upon to continue in flower until the end of the season. During periods of dull, rainy weather they naturally become less free in flowering, but so soon as the sun again predominates they regain quickly their old state of brightness, and are frequently in a very attractive state throughout September and October.

Seeds are sometimes sown in the open ground where the plants are intended to flower, and quite good displays of flowers result from this method late in the season, but where they are to be used as part of a summer bedding scheme, it is of prime importance that they should flower early, and for this purpose every effort should be made to obtain, by the end of May, strong specimens which will commence flowering within a very short time of being bedded-out. The raising of plants for this purpose may be accomplished by sowing seeds in a warm house at the beginning of March. So soon as the seedlings are large enough to handle, prick them off into boxes filled with light, sandy soil and grow them on under buoyant atmospheric conditions, fully exposed to sunshine. They do remarkably well in boxes and, if carefully hardened off, they may be transferred to beds at the end of May without receiving any material check. In showery weather they establish themselves almost immediately, but if planted in dry weather, one good watering may be necessary to establish them. Once they have taken root-hold, however, no watering will be necessary or desirable, as few annuals are so well able to resist the effects of heat and drought—a fact which renders them of especial value on dry, sunny banks where few other things would thrive—as are the Portulacas. *W. A.*

PAPAVER RUPIFRAGUM VAR. ATLANTICUM.

If it is rather troublesome in some gardens, since it seeds freely, this Poppy is such a beautiful plant and flowers so profusely the season through that one willingly puts up with its determination to be a successful colonist. A true perennial, P. rupifragum atlanticum makes a low tuft of narrow, downy, pale green leaves, and to a height of some eighteen inches above these it raises elegant flowering stems. These appear in succession throughout the season until late autumn. They branch freely, always stand erect, and bear large, cup-shaped blossoms in a pleasing shade of tawny-orange.

This attractive Poppy is naturalised here, and there are few places in which it will not grow. Although it seeds so abundantly, and is perennial, it is, unlike the Welsh Poppy, for example, quite easily rooted-out where it is not wanted. *North Wales.*

TREES AND SHRUBS.

MYRTUS NUMMULARIA.

This delightful Myrtle is now getting fairly well-known, and every year some fresh evidence as to its hardiness is vouchsafed. Here it came through the severe trial of the winter of 1927-8 without losing a leaf, and it was in a very cold, unprotected spot. M. nummularia is a native of New Zealand. Its slender, wiry growths are quite prostrate, and these, branching freely, cover the ground with a fine, twiggy network, furnished with small, rounded leaves of a dark, lustrous green. The wood also is glossy and the whole plant has a dark, bronzy hue, especially in winter. The pure white, almost stemless flowers appear in early summer, tufting the branches like balls of fluff. These are followed by fruits which are fully one-third-of-an-inch across and almost globular. They are white, or rosy-white, ultimately ripening to a dull scarlet.

I find this very attractive little Myrtle enjoys a cool vegetable soil, and if the moisture supply is at all doubtful, some mid-day shade is desirable. The branches will root if pegged-down, which renders propagation a simple matter. Indeed, the branches often appear to root naturally as the plant spreads. Cuttings also strike very readily. What extent of ground this plant will cover I do not know. It is not a fast grower here, but, given a congenial soil and situation, with shelter from cutting winds, it will not be long in usurping several square feet. *A. T. J.*

BRUCKENTHALIA SPICULIFOLIA.

This is a charming, miniature plant somewhat resembling the common Heather in appearance. When growing in a mass, and covered with flowers, it is very effective, but it is a beautiful subject even in winter, with its closely packed, deep green leaves.

It grows freely in any good sandy loam or peaty soil, making a delightful group in the Heath garden or on the larger rock garden, where it may be used as a carpet for choice bulbs. *R. F.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XIV—The Delei Valley.

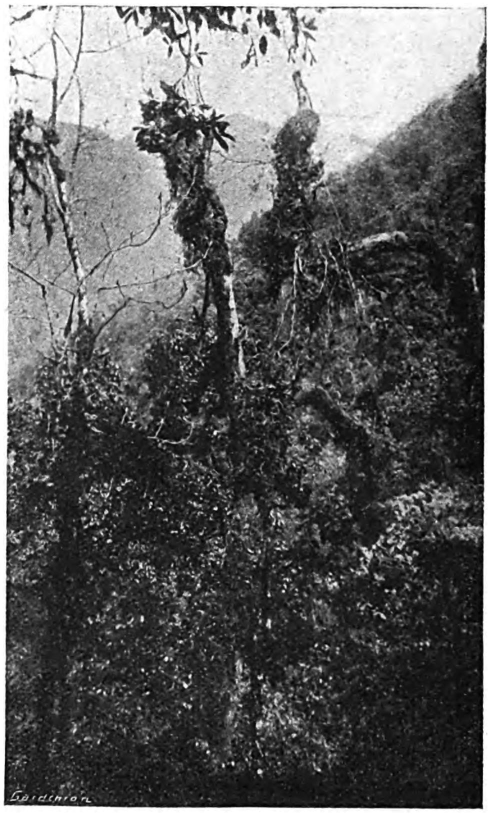

FIG. 70.—TEMPERATE RAIN FOREST: 6,000 FT. ALTITUDE.

The leafless tree on the left is Magnolia rostrata.

The Mishmi path up the Delei valley is difficult from the start. It keeps close to the river, now over boulders in the bed itself, now up and down the cliffs against which the swerving river bangs violently. Only by comparison with the upper Delei can the word 'gorge' be denied to the lower course of the river; and the steepness of the enclosing walls is emphasised by the fact that every side stream leaps the last few hundred feet into the main valley in its stride. The view, both north and south, is blocked out by overlapping spurs and the valley is, of course, lined at the base with tropical or sub-tropical jungle.

In the course of the day's hectic scramble I had no time to botanise, my attention being fully occupied preserving my balance on the rickety ladders, narrow ledges, and galleries, by which the cliffs are scaled; and the only interesting new plant collected was a species of Euonymus, with liver-coloured flowers. The violet Chirita lurked in the shadow of every cliff, and a shrubby, orange-flowered Seneci was common among a variety of familiar Compositae. Although there was no change in the flora as a whole, I noticed a Poplar in the river bed. That evening we camped on a sandbank, and the day, which had begun with a downright drizzle, and remained sulky, passed out into a night of splendour when the moon rose.

My Bamboo shelter, which the Mishmi ran up in twenty minutes, was roofed with the leaves of a wild Banana, whose under surface is coated with snow-white meal in such abundance that the men who cut and carried in the leaves returned looking like millers. If the leaf is gently heated over a fire, the meal quickly melts, and flows as a film of varnish over the bright green leaf, adding a high polish.

The morning was cold with a heavy dew which splashed like rain from the trees. I was up at 5, cooked myself a frugal breakfast, and by 7.15 we were on our way again, still marching in the river bed.

The cliff climbing continued, some of the traverses and descents being perilously awkward. Presently a wall of snow rose into view over the lower spurs in the middle distance. We were surrounded by forest hardly distinguishable from the jungle of the Lohit; nevertheless, when that white mantle appeared, cast over the shoulders of the western range, I felt that at last we were approaching the alps. Alas! for the elusiveness of the Mishmi Hills, where seeing and attaining are two very different propositions.

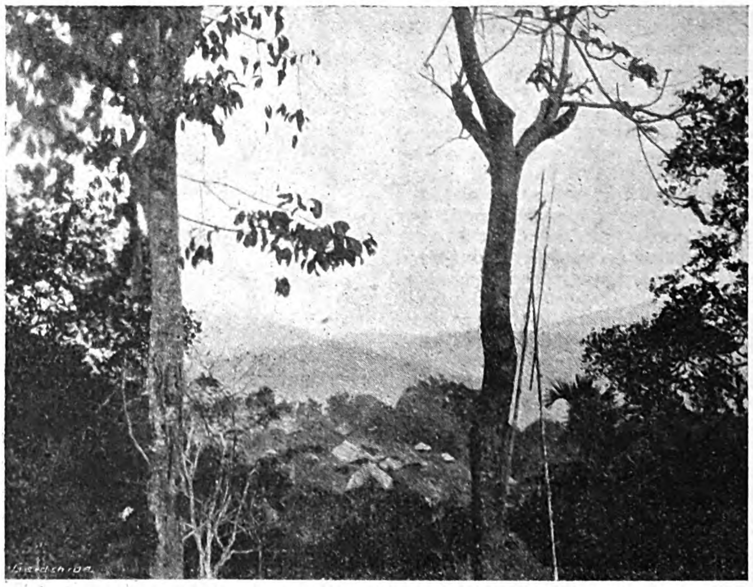

FIG. 71.—A VILLAGE IN THE HILLS.

At last we left the bed of the Delei and turned up a steep, boulder-choked torrent flowing down from the eastern range; gaining the ridge, a climb of about 1,500 feet brought us to Chibaon, a large village scattered down a broad, cultivated slope. Here a site had been selected for us, and although it was not such a camping ground as we should have chosen for ourselves, perhaps, yet on so sultry a day I was glad to pitch a small alpine tent anywhere, and look about me at leisure.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19, and February 2, 16, 1929.

My first care was to get out some stores, both for my companion and myself, and to send off the former, after which I straightened things out a bit. The altitude of our second camp was about 3,250 feet, and not far above us rose the ridge, all shining with the spring colours of temperate rain forest. We faced due west, beneath us was the gorge of the Delei, and beyond, the long, bumpy spurs of the western wall, whose highest visible peaks, 13,000 to 14,000 feet high, were covered with snow. Behind us, that is to say, to the east, a long, easy gradient, for the most part arable land, ascended to a low ridge, with trees along the sky-line, which then rose sharply to well-forested heights; to north and south the mountains threw out long arms which held us in close embrace. Thus the only possible climb was to the east.

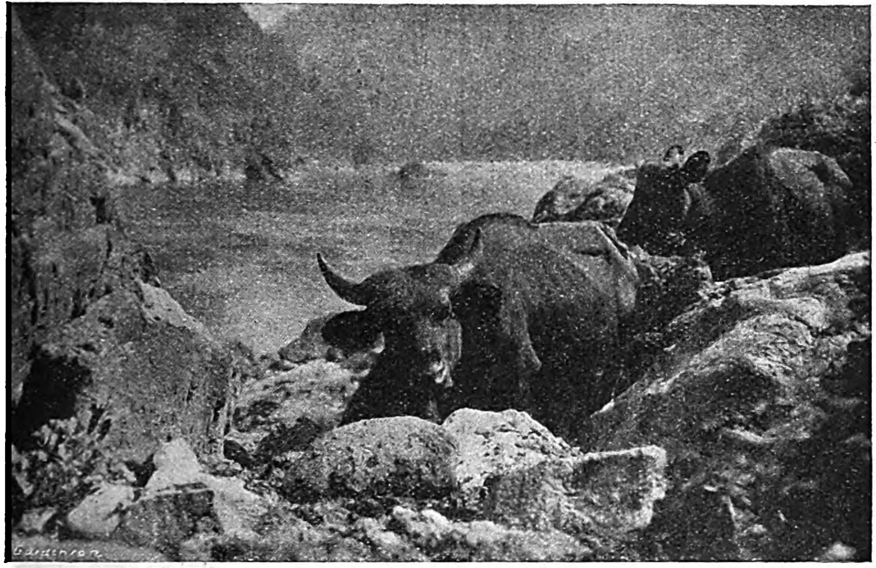

FIG. 72.—MITHUN: THESE ANIMALS ARE SLAIN BY THE MISHMIS IN THEIR RELIGIOUS RITES.

One striking Orchid I had collected on the way up—a Dendrobium; but whether it was a form of D. nobile, or something quite different, I was unable to satisfy myself. Now I was anxious to be up and doing; but as I had to cook my own meals, having left the cook with my companion down the valley, I resolved to rest in camp next day.

The day, April 6, 1928, was fine and hot, and after spending the morning in camp, and looking longingly at the rain forest through my field glasses, I broke my resolve at 2.30 and started up the slope which stretched in dips and curves to the distant ridge. It was further off than it looked. First past a series of huts, and through cultivation (Fig. 73), where Opium Poppies and Peas were much in evidence, then through secondary growth where I found a remarkable Gaultheria, and a very fragrant, white Jasmine. The Gaultheria had very large, cream-coloured flowers, rosy-cheeked like an Apple on one side, and big leaves, rather coarse and untidy; but a month later, when I saw the young foliage, freshly-green and crimson-haired, I changed my opinion. Altogether a promising shrub, although, coming from an altitude of only 5,000 feet, one would suspect it to be delicate. However, it looks robust. The large, blackish-purple fruits ripen early in the rains.

At this stage, I was joined by a Mishmi lad who offered to guide me to the ridge, and we went on over recently felled timber, and so finally to the ridge. Just over the brow was virgin forest, the beautiful temperate rain forest of the Indo-Himalayan mountains. At once I began to notice strange trees and shrubs. One of the first to attract attention was evidently a Podocarpus, but all the specimens I saw had been felled, and were sprouting new shoots which bore no cones. The narrow, linear leaves are from four to six inches long, with two silvery-white stripes along the under surface, one either side of the midrib. Later, I saw trees in the rain forest, intact.

Along the ridge were thickets of Ericaceous and other shrubs, several of them in flower, but my attention was soon attracted to a white-flowered Rhododendron perched high up in the fork of a tree. Shortly afterwards we came to a specimen on the ridge. The flowers are creamy-white, rather than of that otiose and puritanical whiteness so often associated with the 'Maddeni' series, and there is a dash of yellow in the throat. The truss is almost invariably four-flowered, and every shrub exhales a wealth of fragrance. At first sight I felt convinced that here was a new species, but with more material and a detailed examination, I could find little to distinguish it from R. dendricola, or at all events, from the plant collected under that name in the Seinghku valley in 1926. True, it was flowering a good fortnight earlier, but one can attach no importance to a seasonal peculiarity of that sort. The only definite distinction was this: The Delei valley plant had a corolla which was pubescent all over; whereas the corolla of R. dendricola (type) is pubescent only at the extreme base. I am not prepared to separate the former from R. dendricola on evidence as slender as that, and for the present at any rate K.W. 8,016 may be set down as the Delei valley form of R. dendricola. It was quite common in these forests, being almost always epiphytic at its lower level (5,000 feet), and almost always terrestrial, growing on rocks, towards the upper limit (6,000 feet).

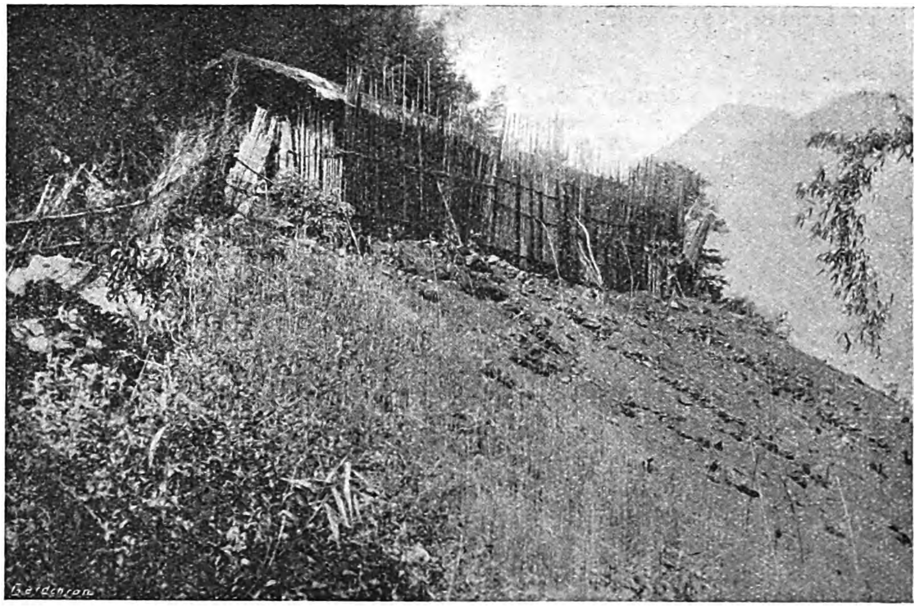

FIG. 73.—A MISHMI HUT PLACED PRECARIOUSLY ON A HILLSIDE ABOVE STEEP CULTIVATION.

Another interesting epiphyte seen on the ridge was a huge Cymbidium, the heavy, drooping spikes bearing a dozen or fifteen flowers with apple-green perianth lobes, and a cream-coloured lip peppered with purplish-crimson dots and dashes.

The sun was now setting, and it was time to turn back if I would reach my camp before dark; nevertheless, I was loth to drag myself away from the first hunting-ground of the season, and lingered on, noting various species "for future reference," and collecting a Pentapterygium. Instead of returning on my tracks, however, I indicated to the guide a route down the ridge bounding our valley, and so to the village; but he, silly fellow, misunderstanding, led me over the hills and far away to the next village, whence a rough two-mile tramp in darkness brought us late to camp.

On the following day—April 7—the weather broke, and it rained all day; I emphasise this because, on the whole, April was an unexpectedly fine month—we had nineteen practically rainless days. I was happily at work in my tent on the plants collected the previous evening, when suddenly out of the drenching rain appeared the cheerful face of my companion, Buttercup. He had experienced much difficulty in getting together the last eight coolies required, but had finally got away from the bridge two days after I left. So the party was united once more, and we were another stage on our journey; I was glad to see our cook, as I was tired of cooking my own meals, and had already fallen back on boiled eggs, biscuits and tea as the line of least resistance. Buttercup also brought with him the mail-runner, who had come from Denning in five days.

We did not anticipate much difficulty in getting coolies here, as there were plenty of small villages in the neighbourhood, and Chibaon itself boasted two dozen huts; but being anxious to push on, I thought it best to indent for them immediately. Meanwhile, the indications were that a few days spent here would not be altogether wasted. So we settled down in Camp II, little dreaming that we were to be there about a fortnight! *F. Kingdon Ward.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

NOTES FROM A NEW ZEALAND PLANT HUNTER.

To a visitor who has been accustomed to European meadows, with their great wealth of showy herbaceous plants, New Zealand is at first rather disappointing. Owing to the climatic conditions, primeval New Zealand was a land of tangled forests and dry, exposed areas covered by coarse, tussock-forming grasses, and so the only spaces left for the development of moisture-loving herbaceous plants were the alpine valleys, and in these the flora is rich, both in species and in individuals, but there are few bright colours, the predominating notes being white and yellow.

The climate of New Zealand is decidedly insular, being rather cool, with no severe frosts, and a rainfall which is both abundant and well distributed, there being no definitely dry or rainy seasons.

Before systematic colonisation by Europeans, little more than eighty years ago, forests covered extensive areas, although, nowadays, comparatively little remains of these virgin forests, except in certain areas of the South Island where several extensive national parks and reserves have been created.

The Southern Alps, which culminate in Mount Cook, some 12,000 feet high, are parallel with the west coast, and from them glaciers descend, in some cases to within a dozen miles of the ocean. This extensive mountain range casts a huge "rain shadow" over the centre of the South Island by intercepting the moisture-laden winds from the Tasman Sea, so that the narrow strip of territory between them and the ocean has over two hundred inches of annual rainfall, while the east coast has under thirty inches, and many of the central parts have much less.

Where rainfall is sufficient, forest conditions prevail, but much of the dry, eastern area is almost treeless, being clad with coarse tussock grasses, of which the commonest are Festuca novae-zealandiae, Poa caespitosa and Danthonia flavescens; among the tussocks grow several herbaceous Senecios, S. bellidioides, S. saxifragoides and S. Haastii, with Bulbinella Hookeri, Helichrysum bellidioides, and several species of small, terrestrial Orchids. In the central dry areas, Carmichaelias, Raoulias, and other curious drought-resisting forms of vegetation have been developed. Where forests have been destroyed by fires, large areas are colonised by the common Bracken, Pteridium aquilinum, which often gives way to Leptospermum species, the Maori name for which is Manuka. L. scoparium is one of the commonest and most beautiful of New Zealand shrubs, corresponding to the Gorse and Broom of European landscapes. It is usually found in pure "stands," which may cover many acres on dry, exposed hillsides. L. ericoides (Fig. 75), when mature, is a tree some forty feet in height, and quite three feet in diameter. Although often occupying poor soil where usually little or no undergrowth is present, it sometimes invades good soil, after a forest fire, in which case it forms a nursery for mixed forest. The forest starts as an undergrowth of mixed plants, and as these reach maturity they gradually choke out the Leptospermums. Such mixed forest consists of Griselinia littoralis, Melicytus ramifloruum, Nothopanax arboreum, N. Colensoi, Schefflera digitata, Dacrydium cupressinum, Podocarpus ferrugineus, P. Hallii, Fuchsia excorticata, Sophora microphylla and others, including several lianas and many Tree Ferns (Fig. 74). In their extreme forms, the Leptospermums are readily identified, but they approach each other very closely, and in many areas they seem to hybridise quite freely. Their beautiful, graceful growth-form and the numerous sprays studded with countless small, white flowers, place them among the most decorative of New Zealand shrubs, but like so many other beautiful plants which are abundant and widely distributed, they are almost entirely overlooked in their native country.

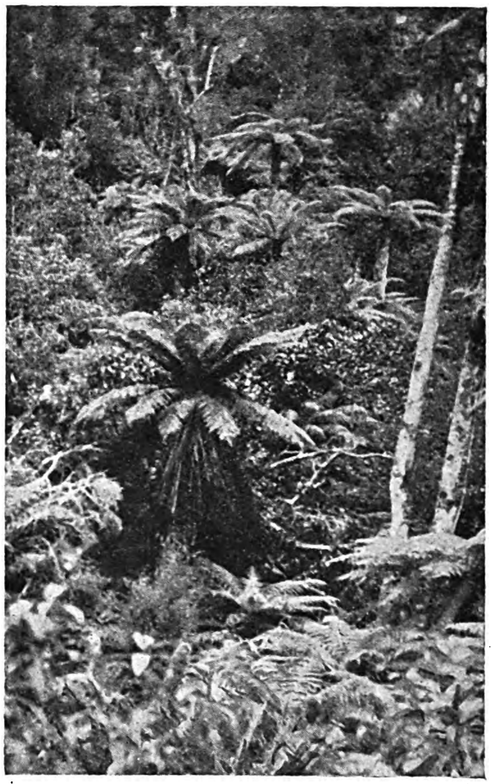

FIG. 74.—NEW ZEALAND FOREST INTERIOR; SHOWING DICKSONIA SQUARROSA.

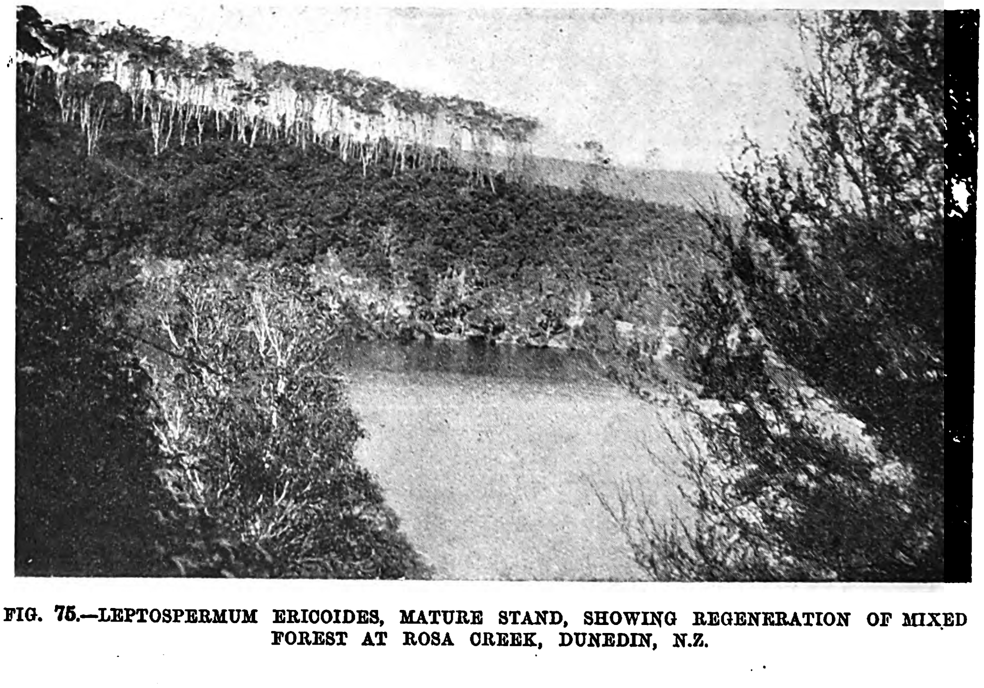

FIG. 75.—LEPTOSPERMUM ERICOIDES, MATURE STAND, SHOWING REGENERATION OF MIXED FOREST AT ROSA CREEK, DUNEDIN, N.Z.

In moist, open places, three giant Monocotyledons—New Zealand Flax (Phormium tenax), the Cabbage Tree (Cordyline australis), and the Toe-toe (Arundo conspicua), are prominent plants, which give the landscape a characteristically exotic appearance which readily catches the eye of a wanderer from the northern hemisphere.

The abundant rainfall and mild temperature produce a magnificent profusion of vegetation reminiscent of tropical jungles, a forest composed of evergreen trees and shrubs, many lianas, numerous Tree-Ferns, and a superabundance of epiphytic and terrestrial Ferns and mosses. The chief trees are Podocarpus dacrydioides, P. Totara, P. spicata, Libocedrus Bidwillii, Weinmannia racemosa, Metrosideros robusta, Quintinia acutifolia, and most of the species already mentioned as mixed forest. The Tree Ferns (Fig. 74), with their curious trunks—some of them quite two feet in diameter—made up of the persistent, scale-like bases of the fronds, are the most conspicuous plants of the forest interior. The most abundant species are Hemitelia Smithii and Dicksonia squarrosa, which grows quite fifty feet in height, being the tallest growing of all New Zealand Tree Ferns. The beautiful Cyathea dealbata, whose fronds have a silvery undersurface, is abundant in many areas, but is rather local in its distribution. The Hymenophyllums and Polypodiums, in many species and an infinite number of individuals, form a luxuriantly-delicate growth, covering the forest floor, and even the tree trunks. Indeed, a glimpse into the interior of a typical New Zealand rain-forest shows abundant reason why this land should be called "The Land of Ferns."

The interesting Kidney Fern, Trichomanes reniforme, is undoubtedly the most striking of the many endemic Ferns of New Zealand. The vivid green, rather leathery, kidney-shaped fronds have the sori inserted around their entire margins. Because it is capable of only slight adaptations to help withstand drought, T. reniforme is found only when the humidity of the air is comparatively high. Other widely-spread epiphytes are Dendrobium Cunninghamii, Earina mucronata, Actilia species, Freycinetia Banksii, many species of Ferns and Lycopodiums, and the interesting Tmesipteris tannensis.

Although the general appearance of the forest is a sombre green, it contains several fine flowering trees, but these are usually isolated specimens, and do little to light up the landscape with a blaze of colour. Sophora microphylla, better known throughout the colony by its Māori name of Kowhai, is certainly a most desirable object when the curious, golden-yellow, Papilionaceous blossoms are produced in early spring. The Rata (Metrosideros robusta) runs the Kowhai close for favourite place in public opinion. In midsummer it bears a great profusion of blossoms, of which the numerous scarlet stamens are the showy part. Other flowering trees worthy of note are Carpodetus serratus, which covers itself with quantities of small white flowers; Pittosporum eugenioides, a pleasing tree of fine habit bearing a wealth of scented, yellow flowers; P. tenuifolium, a graceful subject which produces numerous dark red flowers; and Fuchsia excorticata, a widespread tree found commonly on, or near, the edge of the forest, which periodically sheds its light brown, papery bark, thus preventing its trunk and limbs being colonised by epiphytes. It produces a large number of rather inconspicuous, reddish flowers, which are interesting because of their blue pollen. Aristotelia racemosa, an inhabitant of moist valleys, produces, in early summer, large numbers of dainty, pink flowers, which are, later, followed by clusters of small, dark-red berries.

The forest is prolific in the production of lianas, which begin life as either twiners, climbers or sprawlers. Clematis indivisa, with its huge trusses of delicate, white flowers, is a most attractive member of the genus, while the yellow-flowered, sweetly-scented C. foetida—a misnomer for which Raoul was responsible—is a very dainty plant. Rubus australis, R. cissoides and its peculiar leafless form, R. cissoides var. pauperatus; Muhlenbeckia australis, Parsonsia heterophylla, and a form of Calystegia sepium, are all abundant. Angelica geniculata is an interesting climbing member of the Umbelliferae. Compositae is represented by the yellow-flowered, climbing Senecio sciadophilus, and Myrtaceae — a family which does not perform the feat elsewhere—has several species of Metrosideros which are climbers, M. scandens and M. hypericifolia being the most common. Rhipogonum scandens, a curious Lilaceous plant with reticulately-veined leaves, bears numerous clusters of small, starry, white flowers which are succeeded by comparatively large red berries. *Dunedin.*

(To be concluded.)

NOTES FROM KEW.

In the outdoor garden, at least at Kew, early-flowering shrubs are later than usual in displaying their welcome blossoms. The Rhododendrons in particular are much behind the average date of flowering.

The Hamamelis, or Witch-Hazels, appear to be the least affected by weather conditions. Throughout January, H. mollis, the most beautiful of all Witch-Hazels, produced a wealth of blossoms. These are rich yellow, deliciously fragrant and freely produced in clusters along the leafless twigs. Few flowers are more delightful at this season of the year for vase decoration than those of Hamamelis, H. mollis for preference, arranged with the bronze-tinted foliage of Mahonia (Berberis) Aquifolium. They will last in good condition for upwards of a month and scent the room with their fragrance.

Other Witch Hazels flowering freely at the time of writing are H. arborea, deep yellow; H. japonica, rich yellow, and its variety Zuccariniana, with pale lemon-yellow blossoms. When selecting positions for planting, which may be done immediately after flowering, associate them with evergreens so as to provide an effective setting and background for the leafless flowering shoots, and shelter for the blossoms. The best specimens of H. mollis at Kew are growing in the Buxus (Box) collection, where the soil is a light, sandy loam.

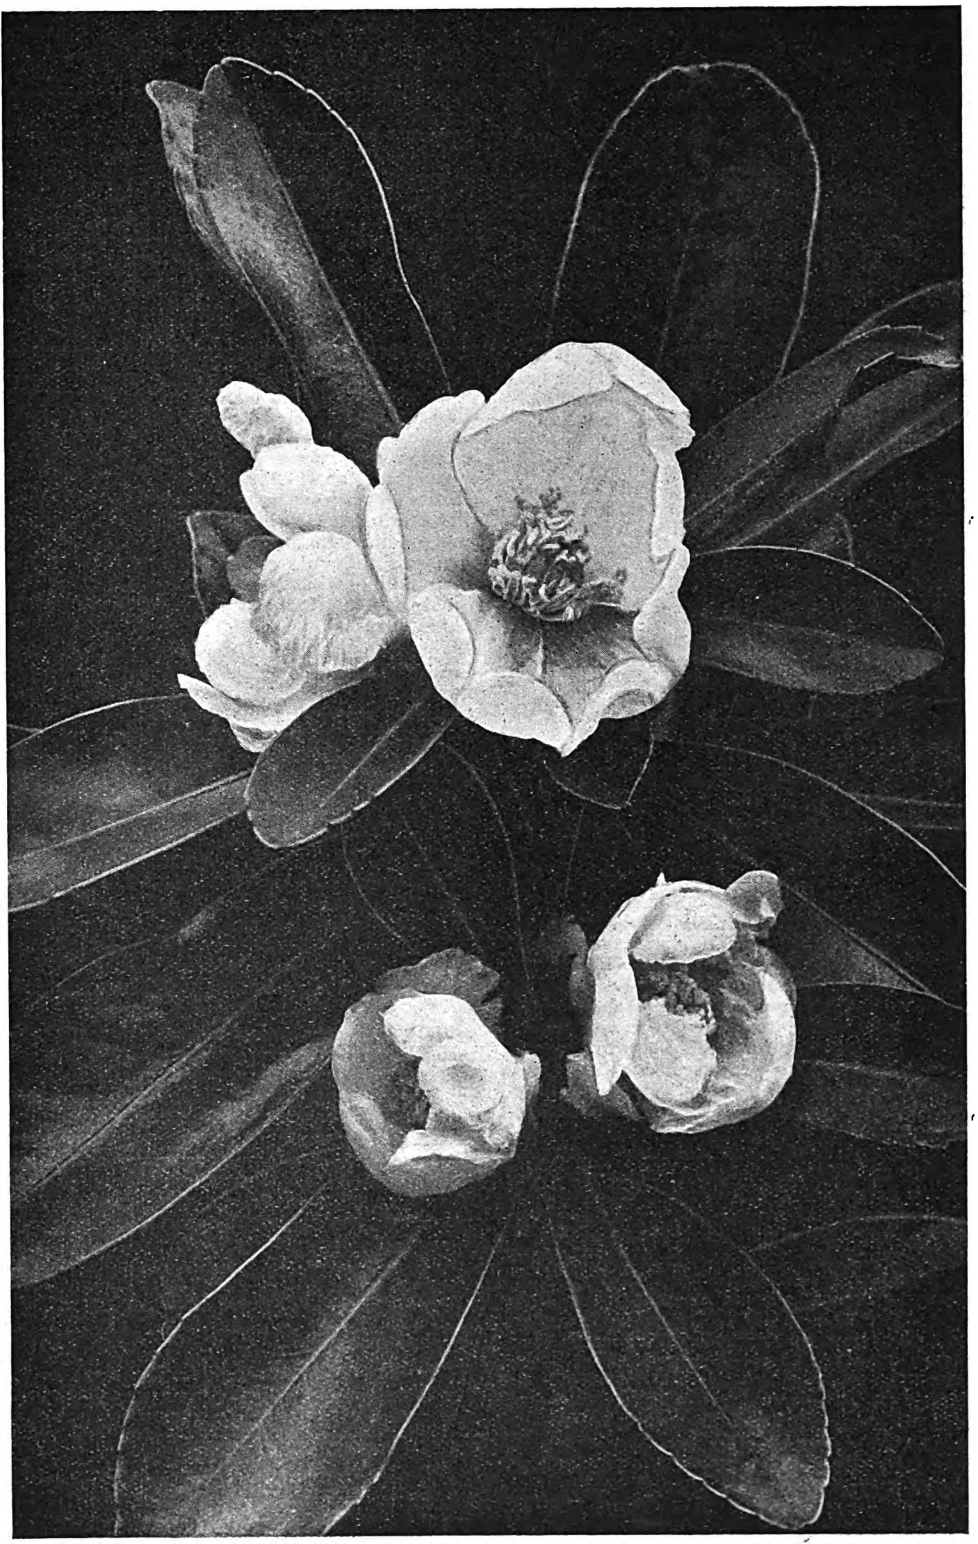

FIG. 76.—GORDONIA LASIANTHUS (?).

R.H.S. Award of Merit, February 12. Flowers white. Shown by Lt.-Col. Messel (gr. Mr. J. Comber), Nymans, Handcross, Sussex.

(see p. 128).

Viburnum Tinus is one of our best-known evergreen shrubs, but is not nearly as much planted as its merit deserves. Although a native shrub of the Mediterranean region and south-east Europe, it is more hardy than generally believed. Thriving in shade, the Laurustinus is a most useful shrub to plant as an undergrowth for tall trees. One of the best examples of this at Kew is under a Lebanon Cedar. As a bush in the open shrubbery border and as a lawn shrub, Viburnum Tinus is an attractive winter-flowering subject, opening its clusters of white flowers from about November to March.

There are several varieties, the most distinct being lucidum, hirtum, pyramidale and purpureum. The variety pyramidale makes a splendid evergreen hedge.

Few shrubs root more readily during late summer and autumn in a slightly heated propagating case or in a cold frame.

Several bushes of the Winter Sweet, Chimonanthus fragrans, are flowering more freely than usual. This, one would be inclined to attribute to the sunny days of last August and September, which ripened the wood. The flowers are produced even more freely on the unpruned bushes in the open than on a closely pruned plant trained against a wall.

Another deliciously fragrant, winter-flowering shrub is Viburnum fragrans, a recent addition to our gardens, introduced by Messrs. Purdom and Farrer. The blooms are, unfortunately, prone to suffer badly from weather conditions in the open, at least, at Kew, and for this reason the shelter of a south or west wall is desirable. A Himalayan shrub, Viburnum grandiflorum, is also in flower on a west wall. The pink-tinted flowers are borne in clusters on the leafless twigs, and both in size and colour they suggest the charming Daphne odora.

The Arbutuses, or Strawberry Trees, are deserving of much more attention in gardens. They are very ornamental, large, evergreen shrubs or small trees, being not only showy and interesting in themselves, but providing an excellent foil in the shrubbery borders and pleasure grounds for spring-flowering trees and shrubs. Further, the reddish or cinnamon-coloured bark is very striking in the winter sunlight against the dark green foliage.

The flowers of the common Strawberry Tree, Arbutus Unedo, have fallen, and those of Arbutus Andrachne are not open, but the hybrid between these two species, A. andrachnoides, as one would expect, is in flower. The Arbutus is one of the few Ericaceous shrubs which will grow on chalky soils.

The dwarf Heaths, varieties of Erica carnea are charming in flower, with a profusion of rosy-pink flowers. A choice of four from among the numerous named varieties might well be James Backhouse, King George, Vivellii, and the dainty, dwarf, white variety alba. *A. O.*

NOTES FROM A WELSH GARDEN.

A SPELL of mild weather in early February may mean retribution and regrets later on, but it is very pleasant while it lasts. Moreover, it does enable a number of early-flowering plants to get their business done with comfort to themselves and satisfaction to us. Rhododendron Nobleanum, for example, which is so often snubbed for its precocity, has had ideal weather for its welcome blooms. So much may also be stated of the Berberis commonly known as B. japonica, or the Japanese Mahonia. This very ornamental old plant does not thrive in this light soil, but, if it is small of leaf and stature, it flowers unusually well, and a bush about four feet tall is now carrying a fine cockade of its fragrant, sulphur-yellow blossoms at every tip. Azara microphylla, always attractive as an evergreen, can be relied upon to flower at this season here in almost any weather. But if it has less to lose, its blossoms being very small and hidden beneath the spreading branches, they are so highly scented that their Vanilla-like perfume can be detected for a considerable distance. Daphne Blagayana is also flowering, and its ivory-yellow clusters are so exceedingly sweet when the temperature is genial that for these alone a mild interlude would be very welcome just now.

But in spite of the open weather the winter-flowering dwarf Heaths are unusually late, and this appears to be a feature of the season elsewhere. In regard to Erica carnea and some of its varieties the phenomenal shortage of rain in January may be the reason. But E. darleyensis is at least six weeks behind its customary date. It has been more normal as to time during winters of much greater severity. Curiously enough, E. mediterranea is more forward than I have seen it for many years, and its Irish form, E. m. hibernica, is even showing colour.

Snowdrops have rarely flowered so abundantly as they have been doing since the first week of February, the blossoms excelling in size as well as in numbers. The old, yellow Dutch Crocus is welcome enough these days in a garden where mice have an epicurean taste for practically all the more expensive kinds, and it has been blazing with its customary heartiness since the Snowdrops came. The only species which succeeds in making any sort of a stand against the enemy, it being comparatively cheap, is C. Tommasinianus, a dainty little thing of palest lavender and silver-grey. The rather later C. biflorus is also tolerably permanent. Leucojum vernum carpathicum is one of the early spring flowerers that one can never get enough of. Its large, almost globular, orange-tipped bells are borne on stalks sometimes eight inches high, and they are slightly fragrant. But, in my soil, at any rate, this lovely plant seems to take years to become properly established, and during the process the bulbs have a way of disappearing.

Cyclamen coum and C. c. album are flowering in the woodland, bright spots of colour among their dull, but very distinctive foliage. Pulmonaria rubra, earliest of its early race, has been in blossom under the trees since January. Its bright, tile-red flowers are very pleasing among the green of the undergrowth, and they have no trace of the family blue or purple in their pigment. A robust grower, P. rubra enjoys considerable space for its large and thongy, rhizome-like growths which bristle with roots that are more often high and dry than anchored in the soil. Moreover, the raspy leaves of this plant will, after flowering, often be over a foot long and eight inches wide. They may be very faintly spotted, but are more often a uniform olive-green.

Anemone blanda var. Ingrami was in full bloom during February's first week, making lovely patches of a soft blue-purple, in various shades according to the age of the blooms. There is nothing more delightful than these, with A. Hepatica and colonies of Eranthis hyemalis, especially where they have been growing undisturbed for years, and the soil has a light covering of moss. The slightly later-flowering E. cilicica will not go unobserved among these, for its "frills" are more deeply cut than those of the older species, while they are distinctly bronzed, and the large flowers, especially when in full sun, are rather a richer yellow. The hybrid, E. Tubergenii, is a compromise between the two species named, with all their good points and a tendency to last longer in bloom, as the flowers are sterile.

Viola calcarata has the reputation of being uncertain in flowering in some gardens. In any case it is hardly a winter flowerer. But coming across an attractive typical plant in a good deep bluish-lavender at Mr. Ingwerson's nursery last spring, this was brought home, and it has never been without blossom since planting. Frost has destroyed the blooms several times, but with the return of milder conditions a fresh crop has always appeared, and it is still flowering with undaunted courage.

There are some variegated evergreens which afford such welcome colour at this season that even those who dislike such things may find their principles shaken. One of these is Aristotelia Macqui variegata, a native of Chili and belonging to the Tiliaceae. The ovate leaves of this shrub, from two to nearly six inches long, are a rich, glossy green, clouded with yellow markings, while the leaf-stalks and the whole of the younger wood is a bright plum-red. The general effect in the winter garden is thus very cheerful, and although the shrub is not hardy, it generally manages to carry its foliage through the greater part of the winter here. Even, when severely injured by frost, it has always started from the base in spring. As a matter of fact, I always cut the plant back in any case, for then one gets finer foliage, and the bark colour of the young growths of the year is much better than that of older wood. These shoots will grow about four feet tall in a season, and they are very elegant in habit. Since there is always, as I have suggested, a chance of the foliage being injured during the winter, a sheltered position is desirable. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

THE GENUS PRIMULA.

(*Continued from p.* 124.)

LANCIFOLIA (Pax et K. Hoffm.). Lance-leaved P. (Nivales.)

A BEAUTIFUL sub-species of P. russeola (Balf. f.), with a tuft of papery, pointed, lance-shaped leaves one-and-a-half inch to three inches long, gradually tapering to a winged stalk; margins revolute and edged with small teeth; upper surface more or less smooth, underside coated with sulphur-yellow meal. Flower stem two-and-a-half to three-and-a-half inches tall, bearing two terminal, rose-coloured blossoms, on slender stalks a quarter- to half-an-inch long. Corolla half- to three-quarters-of-an-inch across, with rounded, blunt, entire lobes; tube cylindrical below, dilated upwards, about equalling the calyx in length. Flowers in July and August. Not in cultivation.

Grows near Beju-Batang, in eastern Tibet, at about 12,000 feet above sea-level.

Culture: Good rich loam, in a damp spot, with protection from wet in winter, is indicated.

LATISECTA (W. W. Sm.). Scalloped-leaved P. (Cortusoides-Geranioides.)

A handsome, deciduous, perennial species with a slender rootstock which produces a sparse tuft of membranous leaves, with broadly heart-shaped blades about two inches long, very deeply cut into about seven, narrowly egg-shaped lobes, with wide, rounded notches between each lobe; both surfaces clothed with long, white hairs, the underside densely so; the blades are borne on slender stalks about four inches long, covered with long hairs. Flower stem about six inches tall, slender, more or less hairy, bearing an umbel of two to four rose-coloured blossoms on erect stalks about half-an-inch long. Corolla about three-quarters-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, smooth, about five-eighths-of-an-inch long. Flowers in June.

Grows in dense, shady forests on Nyima La, in Tibet, at 11,000 to 12,000 feet above sea-level.

Culture: Rich loam and Oak or Beech leaf-soil, in a cool, shady spot, with protection from damp in winter, should suit it.

LEGENDREI (Bonati). Legendre's P. (Souliei.)

This pretty, dwarf perennial is a sub-species of P. Souliei; it produces a tuft of smooth leaves about two inches long, with oval, blunt blades about three-quarters-of-an-inch long, heart-shaped at the base, contracted into a long, thread-like stalk; margins edged with comparatively large, regular, rounded teeth. Flower stem hollow, three to four inches long, bearing an umbel of about half-a-dozen violet blossoms with a white tube, on erect stalks about three-quarters-of-an-inch long, mealy at the tip. Corolla flat, about three-quarters-of-an-inch across, with linear, deeply bifid lobes; tubes cylindrical, about three-eighths-of-an-inch long, longer than the calyx. Not in cultivation.

Grows on sandstone on the mountains of Oua-Pao-Shian, in western Szechuan, at about 10,000 feet above sea-level.

Culture: Friable loam, containing lumps of sandstone, in a cool, half-shady spot, with protection from damp in winter, is indicated.

LEPTA (Balf. f.). Slender P. (Muscarioides.)

A small, delicately formed species with rosettes of thin, papyrus-like leaves about two inches long, with broadly lance-shaped or oblong-ova blades, rounded or blunt at the tip, gradually tapering to a winged, or shortly contracted into a wedge-shaped, stalk; margins edged with regular, blunt teeth, fringed with fine hairs; upper surface pale green, clothed with short down, underside glaucous and more or less hairy. Flower stem fragile, two to six inches tall, more or less coated with yellow meal and bearing a small, crown-like head of very deep purplish-blue, deflexed, and fragrant blossoms.

Corolla tubular above, then concave, about three-eighths-of-an-inch long, with rounded, obscurely retuse or toothed lobes, mealy within. Flowers in July.

Grows in damp, open pastures, on the mountains north-east of Chungtien, in eastern north-western Yunnan, at 13,000 to 14,000 feet above sea-level.

Culture: The conditions recommended are good friable loam, in a well-drained spot plentifully supplied with water when the plant is in growth. *A. W. Darnell.*

(*To be continued.*)

A FUNGUS DISEASE OF MECONOPSIS.

During the past season it was noted that several of the Asiatic species of Meconopsis were attacked by a fungus which may prove to be an unwelcome addition to the ranks of parasitic fungi attacking garden plants. The fungus concerned, Peronospora arborescens (Berk.) de Bary, is very closely allied to, if not identical with, the species attacking the common Corn Poppy, and also Papaver somniferum, in which it causes the well-known Opium Poppy blight in China and India. Since it is known to bring about serious losses in the Opium Poppy fields, and since, in one case at least, it proved very destructive in this country to the beautiful M. Baileyi,* it is advisable to put readers of *The Gardeners' Chronicle* on their guard, by pointing out the facts so far as known, and by suggesting appropriate treatment. It is far from the purpose of this article to cause anything in the nature of a scare. Where the fungus is absent, there is no reason to anticipate trouble, but where it is already lurking in gardens, unless proper precautions are taken, its spread to Meconopses must be expected.

It should be pointed out at the outset that although the new disease is technically classed as a "downy mildew," or "false mildew," it is quite distinct from the true or "powdery mildews," and consequently bears no resemblance to the common white mildew which not infrequently attacks Meconopses especially under glass. This latter disease is relatively harmless, but in order to prevent confusion with the more serious malady, it may be well to point out the differences between the two classes of fungi.

True or "powdery mildews" are familiar to everyone by their conspicuous white appearance. The various species concerned belong to the family Erysiphaceae, examples being the common mildews of the Rose, Chrysanthemum, coppiced Oak, Euonymus, Vine, Gooseberry, and of many others. The white appearance is due to the presence of an external mycelium (spawn) on the surface of the leaf or shoot. The mycelium produces spores in abundance, and it is chiefly from these that the mildew acquires its mealy appearance; hence the term "powdery." The fungus is entirely external, except for minute suckers by means of which it obtains its food from the leaf.

"Downy mildews" (or "false mildews," as they are termed on the Continent) belong to the family Peronosporaceae; they are much less conspicuous, but bring about more injury. This is due to the fact that the mycelium is not superficial but internal. Sooner or later the attacked tissues are killed, and the result is seen in blackened areas in the leaves, or if the attack is severe, in the blackening of entire leaves and shoots. The "downy mildews" are, fortunately, less familiar in gardens than the "powdery mildews," although examples occur in many of our native plants. That most notorious parasite, the Potato blight fungus (Phytophthora infestans), is a very close ally. The summer spores of the false mildews are produced on filaments which protrude through the stomata usually on the under-surface of the leaves. The spores and filaments appear as a greyish mould, which has led to the somewhat inappropriate name of "downy mildew." Resting spores formed within the leaf tissue also occur.

Distribution of the Disease and Species Attacked.

No attempt was made to obtain a complete or exact idea of the incidence of the disease on Meconopses last season, but the fact that it occurred in England, Scotland and Ireland, shows that it is widely spread. Specimens were received from Perth, Northampton and Kent, and it was observed in Surrey and in a garden near Aberdeen. Reports were also received of its occurrence in Middlesex. The first and most severe attack was reported from Ireland, specimens being received at the end of May. It was the publication of the note in *The Gardeners' Chronicle* of June 9, 1928, recording this outbreak, which led to other specimens being received for investigation. Evidence was supplied that the mildew occurred in north Middlesex in 1927. The presence of the disease was, however, far from general, since in response to enquiries several well-known growers of Meconopses replied that their plants were quite healthy. Ther was, moreover, no trace of the parasite at Kew, nor was it observed at Edinburgh or Glasnevin, although carefully searched for.

Of the species attacked, the most susceptible appears to be M. betonicifolia forma Baileyi, although a bad attack was also reported on M. grandis from Perth. Slight traces of the fungus were noted on M. Wallichii, M. superba, M. simplicifolia, M. paniculata, M. Prattii, M. latifolia and M. integrifolia, in one or other of the various gardens concerned.

Description of Symptoms and Life-History of the Fungus.

The symptoms of the disease are very definite. It shows itself first as small, blackish spots or blotches on the leaves, and these, particularly in damp weather, rapidly increase in size. The blotches, which in outline are often elongated rather than circular, may occur on any part of the leaf or petiole, and on M. betonicifolia forma Baileyi, at any rate, are deep black or almost blue-black in colour. The distinguishing feature of the disease is the presence of a grey mildew or mould on the underside of the blotch, especially along either side of the veins. This represents the fructifying stage of the fungus, consisting of exceedingly fine-branched filaments (hence the specific name arborescens) bearing spores, and its presence serves to distinguish the blotches from injury due to weather and from so-called "ordinary decay." The filaments and spores are very characteristic, and to a mycologist are instantly recognisable when examined microscopically. To the layman, the presence of the very minute grey mould on the underside of the leaf will be a sufficient guide.* If the weather be damp and mild, many infections may take place and, as the Irish specimens showed, the whole plant, including the shoot and flower buds, may be involved, and become blackened from top to bottom.

The mycelium (or spawn) of the fungus is internal, and it is only the finely-branched filaments which emerge in order to bear spores. These summer spores (or conidia) are produced in great numbers. They are short-lived, but are blown or washed off and germinate readily on damp foliage. The germ-tube of the spore enters the leaf, develops mycelium, and by killing the leaf tissues produces the black blotches. The special function of the conidia is to propagate the fungus during the growing season. When the parasite has destroyed the tissues, and, in consequence, is faced with a food shortage, it produces inside the dead tissues reproductive bodies of another kind, namely, resting spores. These are formed by a sexual process peculiar to the family Peronosporeae. They have a thick protective coat, and their function is to tide the fungus over an unfavourable period. They fall to the ground with the decaying leaves, and remain dormant until the following spring but, like weed seeds, probably all do not germinate the next season. In the spring the lowermost foliage of the Meconopsis in contact with the ground is readily infected by the germinating resting spores, and thus the cycle of the disease is completed. Once the lower leaves are infected the mycelium develops within the tissues, and after a few days bears conidia, which, blown away, germinate and start a new infection.

Many successive infections and generations of conidia may be produced during the season, and in all probability each one develops its own crop of resting spores.

There is also the possibility of the existence of an additional method of hibernation, namely, that of resting mycelium in the leaves or crown of infected plants, as has been shown to be the case with several other species of the Peronosporaceae. This is a point of practical consequence, since, if such hibernating mycelium exists, the disease would develop again in the spring without infection by spores.

Identity of the Fungus and its Distribution.

The fungus Peronospora arborescens attacks, as before mentioned, many members of the Papaveraceae, and is usually regarded as a single species. It was originally described by Berkeley in 1846 on the Corn Poppy (see *Journal* of the Royal Horticultural Society, Vol. I, p. 31), who appended to the formal description the note "the plants are attacked when quite young, and have a peculiar aspect by which they may be known at a distance." Among its other host plants are Papaver somniferum, P. dubium, P. Argemone and Meconopsis cambrica, and its presence on these plants is not uncommon. No records have been traced of the disease occurring in Papaver orientale, P. nudicaule, P. alpinum, or on the Shirley Poppy, although this does not imply that they are not subject to attack.

Some mycologists, notably Gäumann (see *Beiträge zur Kryptogamenflora der Schweiz*, Band V, Heft 4) believe that P. arborescens may be a composite species, or, at any rate, consists of a number of strains, each of which only attacks a particular host plant. Such specialisation is known to occur in the "rust" fungi. Small differences in form and size of the spores may be traced in the Poppy parasite, but, as far as I am aware, no experiments have been carried out to test the pathogenicity of the fungus on various hosts, and certainly none on Blue Poppies. Until this has been performed and the existence of definite strains proved by experiment, one can only consider the fungus as having a large range of hosts, and be prepared for our garden Meconopses to be infected by spores from any other member of the Papaveraceae.

A statement may be made here as to the occurrence of the Peronospora disease of Poppies in countries outside Britain. In Europe, the fungus has been recorded from most countries on one or other of the hosts already mentioned. It is, however, best known on the Opium Poppy, and during recent years local outbreaks of some severity have been recorded from Austria and from Yugoslavia, where, as is well-known, this Poppy is cultivated for the seeds, which are used for flavouring cakes and sweetmeats.

The importance of the Opium Poppy blight in the east may be judged from the fact that Watt, in his *Dictionary of Economic Products of India*, devoted six pages to the subject and summarises the lengthy account given by J. Scott in his *Manual of Opium Husbandry*. Butler, in his book *Fungi and Disease in Plants*, gives a more up-to-date account, and states that it occurs every year in the Opium-growing tracts in Bihar and the east of the United Provinces. In some years there are localised attacks of great severity, and occasionally epidemics over considerable areas, for which spells of damp humid weather are responsible. Butler further remarks that in the moist climate of Lower Bengal the ornamental varieties of P. somniferum suffer so much that they are as a rule not grown in the Calcutta Botanic Garden. The fungus is also stated to occur in Algeria, Egypt and Japan.

---

* As a result of recent investigations, the Kew and Edinburgh botanists are agreed that M. Baileyi is probably a geographical form of M. betonicifolia (using that name in a wider sense than originally defined). See note entitled, "The Status of Meconopsis Baileyi," by G. Taylor, *Gard. Chron.*, Jan. 22, 1929, p. 66.

* The only other fungus which could be mistaken for Peronospora is the common mould, Botrytis, which attacks dead tissues and which is familiar enough to most gardeners.

Origin of the Disease in Britain.

There are clearly two possible explanations as to the origin of the outbreak of Peronospora in Meconopsis in these islands: (1) That the fungus was introduced from the east by means of resting spores mixed with the seeds or, (2) that it has spread from the infected Papaveraceae in our gardens to the newly-introduced species of Meconopsis, this being effected either by air-borne conidia or resting spores in the soil. The balance of evidence is strongly in favour of the latter, although proof has not been supplied by actual observation.

With regard to the first alternative, if the Himalayan Meconopses have their own particular strain of P. arborescens and cannot be infected by spores from Papaver, Meconopsis cambrica, or other members of the Papaveraceae, it follows that contaminated seeds is the only possible explanation. It is well-known that in the Corn Poppy resting spores of the fungus are produced not only in diseased leaves, but in the flowers and even in the stamens, and it is possible that they may form also in the ovary wall. Flowers of the Opium Poppy are similarly affected. Hence, it seems conceivable that Meconopsis seeds contaminated with resting spores might easily have been received. It should be remembered, however, that such diseased capsules would almost certainly be shrivelled and devoid of seeds, and would thus be disregarded by collectors.

The following definite observations lend no support to the view that the disease has been introduced with the seeds. The fungus has never been noted on plants in the seed-pans or in the early stages of the growth of seedlings raised in this country; and, at Edinburgh particularly, where many thousands of plants have been reared, all have been healthy. If the seeds were contaminated, the disease would almost certainly have shown itself in the young seedlings.

With regard to the second alternative there is, except in one case, no definite information as to the origin of the outbreaks. In the Perthshire garden, however, there is strong presumptive evidence that infection arose from Meconopsis cambrica. This evidence was supplied by Mr. Andrew Harley, of Blinkbonny, Kirkcaldy, who wrote as follows:—"The Meconopsis grandis and M. integrifolia in Perthshire were grown in soil where M. cambrica had grown for many years. In this part of the garden the plants suffered very badly, much more so than in other parts." M. cambrica is known to be attacked by Peronospora, and there can be no reasonable doubt that in this instance resting spores were present in the soil. Possibly, also, odd seedlings of this species affected with the disease occurred around the bed, and from these air-borne conidia would have been distributed.

Methods of Control.

The recommendations given below are for those who wish to take all possible steps to prevent an outbreak of Peronospora. As already indicated, there is no cause for alarm, and when an outbreak occurs, serious development need not necessarily be anticipated, except in damp, warm weather. But many readers prize very highly their collection of Meconopses, and for such full, even if rather elementary, instructions are appended.

(1) Isolation from other Papaveraceae.—It is believed that all existing outbreaks have been due to local infection, and that this may take place by means of spores blown from the leaves of infected Papaveraceae in gardens, or from the Corn Poppy in fields. It is of great importance, therefore, to keep Meconopsis plants isolated from other Papaveraceae in the garden, and to prevent, if possible, the common Red Poppy developing as a weed in the immediate vicinity of the beds.

(2) The Avoidance of Contaminated Soil.—Those outbreaks which have not arisen from infection by air-borne spores must have almost certainly developed from resting spores present in the soil. Such resting spores would be present if M. cambrica or any species had been attacked by Peronospora, and the affected leaves had been allowed to fall to the ground. As a precaution, it would be unwise to plant a Meconopsis in a site where any of these plants had been grown, since, although unobserved, Peronospora may have existed. It is obviously most important not to plant Meconopses in spots where disease has occurred previously, unless great care has been taken to remove diseased foliage before it fell to the ground. For valued species, it would be best to make new beds far removed from the old site.

(3) Varying Susceptibility of Species.—Different varieties of the Opium Poppy are known to vary markedly in their susceptibility to the disease, and it is practically certain that the various species of Meconopsis will be found to show similar variation. Further observations are required, but it would appear that M. betonicifolia and M. grandis are the most likely to be seriously injured. It would be advisable, therefore, to give these species special care in the way of the most favoured sites.

(4) Treatment of Attacked Plants.—Should the disease develop, treatment will vary according to the number of plants involved and the value placed on each individual. Comfort may be derived from the knowledge that a spell of bright dry weather will probably check its development and its spread. If observed in the early stage, it would be advisable to remove with scissors infected leaves or parts of leaves, and collect these in a cardboard box which could be burned *in toto*. If not noted until spots are large and numerous, it may be advisable to sacrifice entire plants. This, however, should be done with care, since the spores are easily shed and wafted away. Special watch should be kept in spring on plants which showed traces of the disease the previous autumn.

(5) Disposal of Diseased Material.—Old, diseased foliage contains both types of spores, the summer conidia on the surface and the resting spores within. It should therefore be taken away with as little shaking as possible, and placed in a box and burned. It should be remembered that after handling diseased plants the hands are liable to be contaminated by spores, and that it would be unwise to touch healthy plants.

(6) Old Plants.—It has been noted that the disease sometimes develops rather extensively on the old foliage after the plants have flowered. Old plants, therefore, if not wanted for seeds or other purposes should, if disease is feared, be dug up, carefully removed and burned. All dead leaves fallen to the ground should naturally also be collected and burned.

(7) Disposal of Poppy Refuse.—It would be advisable to make a point of burning all old Poppy plants and also Meconopsis cambrica, rather than allowing them to decay on the ground or be thrown on the rubbish heap, since, although unobserved, the disease may have been present and the old plants may harbour resting spores.

(8) Fungicides.—So far, no exact experiments have been carried out with the use of fungicides. It is possible that a liquid copper fungicide applied to both sides of the foliage would be effective as a protective coating against germinating spores. No soil fungicide is known which will kill the resting spores.

Further Research.

The present article furnishes a general account of the parasite concerned, records the occurrence of the disease in Britain and suggests treatment. Research is now needed on the Meconopsis disease itself. Of the many problems which require investigation, one of the most important from the horticultural standpoint is the question of the existence of physiological strains within the species Peronospora arborescens and, if these be found to exist, to ascertain from which of our wild or garden Poppies the Meconopses can be infected. Research on infection by resting spores from soil known to be infected is also required, and also on the length of time these spores retain their vitality in soil. The value of the application of a fungicide, either in powder or liquid form, is naturally in need of early investigation. From the scientific standpoint, the fact that the fungus develops easily and rapidly in Meconopsis and goes through its whole life cycle, including the sexually produced resting spores, renders it a useful subject for conducting research on this interesting and important group of parasites.

The disease does not occur at Kew, and it is inadvisable to introduce it even for experimental purposes. The research is therefore being undertaken at Wisley (where the fungus already exists), and is in the hands of Mr. Donald E. Green, the mycologist on the staff of the Royal Horticultural Society's gardens. *A. D. Cotton, Kew.*

HOME CORRESPONDENCE.

Root-stock Problem in Apple-growing.—I was pleased to see Mr. Cobb's reply in your issue of January 19, p. 52, to my notes on the above subject in connection with commercial Apple-growing. His statements are very reassuring, but not altogether consistent with the views of several market growers. Mr. Cobb states, "The fact that we import millions of pounds-worth every year is proof that there is a market here." Quite so! The fact that the foreigner has to show us that there "is a market here" is of no credit to our commercial growers, but rather the reverse. Would it not be much better if English growers could monopolise the markets instead of the foreigner, as is the case now? It may be stated that is what English growers are trying to do, but they have been trying for a good many years. What I think is generally misunderstood is that, for various reasons—climatic conditions, etc.—fruit growers in this country are severely handicapped when competing with the foreigner. According to Mr. Cobb, all one has to do is to produce high class fruits and, having produced them, they can be disposed of profitably. That may be so in isolated cases, but is it so generally? If Mr. Cobb can answer this query in the affirmative, then I shall indeed be pleased, as I should like to see many more thousands of acres under Apple cultivation in this country. But, as I hinted above, it is not always that our fruits are inferior, it is the cost of production which seems to me to be the drawback. The same may be stated of Grapes where quantities are concerned, for foreign Grapes have the monopoly. Big market growers at Worthing, etc., have destroyed their vines. I quite agree that this country is capable of producing the best fruits in the world, hardy or otherwise, but can we produce them at a profit? Mr. Cobb states there has been a lot of ink spilled over the packing and grading of home-grown Apples, but adds that it is now admitted that the English grower has nothing to learn from overseas. Probably he has finished his education! Getting back to the "root of things," I should like to state that what really prompted me to write about the root-stock problem was that several people I know wondered as to where the "problem" lay. Why a problem? I know an experimental station where there are trees that have been planted upwards of twenty-five years, and they are admitted to be all that could be desired, so far as fruiting and uniformity of growth are concerned. These trees are not on selected stocks, yet, although the idea is not new, I daresay that in a few years' time, all our commercial growers will adopt the American method and graft direct on to the root. In fact, I have reason to believe this subject is receiving attention now at some of our experimental stations. But are we not behind in this? Overseas they have practised it with success for the past twenty-five years, all trees, of course, being grown as standards, as they will here eventually. *H. Howard Grace.*

Parrotia persica.—The gardener brought in some seeds which he found lying on the ground under a Parrotia persica. On consulting W. J. Bean's *Trees and Shrubs Hardy in the British Isles*, Vol. II, p. 122, I find, "Seeds afford the best means of increase, but failing these, it may be propagated by layers." We have not seen seeds in previous years, and could hardly have failed to notice them had they been forthcoming. The little "nuts" look very tempting, and should form attractive morsels for the mice who devour the seeds of a Eucryphia pinnatifolia which is close to the Parrotia. Possibly, our tree has only now reached the age at which fruits are produced, or it may be that the favourable summer and autumn of 1928 were accountable for their appearance. Our tree is some forty years old. *A. C. Bartholomew, Reading.*

Rainfall at the Cheshire School of Agriculture, 1928.—The total rainfall, as recorded in these gardens during 1928, amounted to 32·39 inches, that is, ·38 inch less than the total for 1927. The heaviest rainfall for twenty-four hours occurred on June 7, when ·90-of-an-inch was registered. The two driest months were May and September, when ·84 and ·90 inch were registered respectively. In June the rainfall amounted to 4·62 inches; this was the wettest month of the year, with twenty-three rainy days. There were 253 days on which ·01-of-an-inch or more was registered, and 168 days on which ·04-of-an-inch or over was recorded. The driest period was from July 8 to July 20, when there were twelve fine, dry days. The hottest day was on July 15, when the temperature rose to 87° in the shade. The coldest day was on December 14, when the temperature fell to 15°F. only. There were 112 days when no rain fell. The year 1928 was a good year—the crops were excellent and very healthy. It was also one of the best fruit years we have had. The above records are so similar to those of Mr. Allan's, of Tirley Garth (p. 57), that I thought they would interest your readers. *W. E. Shewell-Cooper, C.D.H. (Lond.), Horticultural Superintendent, Cheshire School of Agriculture.*

Gardeners' Pay and Status.—Having engaged in horticultural work all my life, and having foreign experience, I, with your other correspondents, consider that something ought to be done to protect gardeners against those who call themselves gardeners, know little of the work, and obtain employment at a low wage. I have been a life-long reader of *The Gardeners' Chronicle*, and during the war had it sent me, week by week, in Palestine, the Sudan and central Africa, and in places where I used to visit Kew men and endeavoured to learn all I could horticulturally. Since the war, I have taken up the profession of jobbing gardening, and I find it difficult to make ends meet, as the people in this part of Essex will not pay a decent wage for a professional man, so long as there are policemen, postmen, railway men, greengrocers and farm labourers going round in their spare time doing the work for sixpence to tenpence per hour. Is this what gardeners left their jobs in 1914 for? I can sympathise with *B. C. C. Button, Cranham.*

Perpetual-flowering Carnations from Seeds.—Where time and space permit, raising Carnations from seeds is a fascinating and interesting hobby, and although there are numerous varieties already in cultivation, there are possibilities of still further colours and shades as an additional inducement to try one's luck with seedlings. Seeds are easily obtained by means of hand fertilisation, but it is advisable to select the finest plants for the purpose, and as seedlings never come true to the parent plant, it is useless to try to raise a batch of any one particular variety from seeds. Several leading Carnation growers offer seeds at a reasonable price, which is, perhaps, preferable to saving one's own, for by saving it one knows the parent plants, whereas by purchasing it one is in the dark as to the parentage—a more sporting chance. Seeds may be sown at any time of the year, although it is preferable to sow them in the autumn in sandy loam, in pans, place them in a temperature of 60° to 65°, and cover with a sheet of glass. Germination should take place in a few days, when the pans, should be placed near the roof glass. Prick off the seedlings so soon as they are large enough to handle, using good sandy loam, and taking care not to apply too much water, as overwatering may cause the seedlings to damp off. When the seedlings are large enough, pot them into small sixty-sized pots in a similar compost, and keep them near the roof-glass. By the spring they should be gradually hardened to a temperature of 50° to 55°, and subsequently may be grown with the season's batch of rooted cuttings. They should be stopped once, and when rooted sufficiently potted into four-inch pots, using a compost of good loam, mortar rubble, wood-ash and a dusting of bone-meal, with an addition of sand. As a percentage of the seedlings are sure to come single, it is not advisable to pot them on into large pots, five-inch or six-inch pots being ample; neither is it advisable to stop the plants more than once, but to let them flower so soon as possible to ascertain their quality. If the plants are only stopped once, they should flower within fifteen months from the time of sowing, and by flowering them in this way the singles can be discarded so soon as detected. From a small sowing of hand-fertilised seeds sown in autumn, 1927, I raised fourteen plants, eight of which came double, with flowers of good size and quality, the colours being two yellow-ground Fancies, one white, two reds, one red-flaked on crimson, one flesh-pink, and one deep rose-pink; this gives an idea of the colour variations one obtains. *A. J. Turner, Newton Park Gardens, Burton-on-Trent, Staffs.*

Partial Soil Sterilisation.—I am again writing to answer some of Mr. Summerfield's queries and criticisms (see p. 67). (1) I would point out, first of all, that we have carefully tried all known methods of soil sterilisation for a year, including the method suggested by Mr. Holmes Smith; (2) that in our baking method the soil is only brought up to 210°F., and thus the beneficial bacteria are not destroyed, as Mr. Summerfield suggests; (3) even with completely sterilised soil, there would be reinfection from watering with ordinary water (the only way to prevent such reinfection would be to water with sterilised water); (4) in the baking process the soil emerges still damp—not dry as powder—and so it is impossible for plant foods to be lost as "gas" any more than it is with steaming. In my opinion, we want a cheap and yet efficient machine, and in the Reaseheath steriliser we believe we have it. *W. E. Shewell-Cooper, Horticultural Superintendent, Cheshire School of Agriculture, Reaseheath, Nantwich.*

——I would suggest to *G. W. M.* (p. 107) that he should start sterilising his soil much earlier. There is always room in empty houses to place it after Christmas, and a temporary floor is easily formed. I should never dream of sowing seeds in warm, sterilised soil; I turn it over frequently for six weeks before using it for seeds, and find it much better thus treated. Soil should not cake up if used at the right texture. *Interested.*

Lapagerias.—It would not be easy to add anything to Mr. J. Comber's practical information on the cultivation of these beautiful flowers, (*Gard. Chron.*, February 2, p. 76) and my object in writing is quite different. It is to ask if any readers remember the beautiful display which, in the old days, was a feature of the great corridor in the once-famous Royal Exotic Nurseries of Messrs. James Veitch and Sons, at Chelsea. It is just fifty-two years since I first saw this wonderful picture, and it made an ineffaceable impression on my mind. I had been taken to the nurseries by my father with a view to an engagement, and this having been promptly settled by a kindly nod from the chief, whom I came to love and respect so deeply, I had for several years ample opportunities of seeing the display again. It was an annual feature, and was greatly admired by all visitors. It may be that some veteran or other whose eye happens to fall on this note may recall it as vividly as I do after more than half-a-century. If so, he will share in my appreciation of Mr. Comber's admirable article, and hope that it will tend to revive interest in these lovely flowers. *W. P. W.*

Number of Florets in an Exhibition Chrysanthemum.—I, like Mr. A. W. Warner (p. 107), was curious to know how many florets there were in an exhibition Chrysanthemum bloom, therefore, on December 16, 1928, I chose a very good bloom of William Turner, and to my great surprise found it to contain the amazing number of 2,112 florets. *Ralph E. Street, Gardener to The Royal School for the Blind, Effingham.*

SEED POTATO INSPECTION.

Some Reform Needed.

We are at the period of the year when seed-sets of Potatos form a very important item in the agricultural outlook. Than in the northern half of the kingdom, there is no district in the British Isles more famed for its seed Potatos. A magnificent connection has been built up, and it is pleasing to note that not a little of this fine work has been done by skilled gardeners who, anxious to better their lot, have forsaken the garden to devote their whole time, skill, and energy to the production of seed Potatos. The inspection of seed Potatos by the Scottish Department of Agriculture is, however, causing some perturbation in seed-growing districts. In this respect it may be interesting to many growers to have the views of Mr. John Chisholm, Ladysbridge, Banffshire, whose reputation as a seed Potato grower stands deservedly high. Discussing the matter, Mr. Chisholm states that since the Board (now Department) of Agriculture for Scotland instituted a scheme of crop inspection for purity some ten years ago, remarkable progress has been made in the production of reliable seed-sets. The scheme, however, may now be said to have achieved its object so far as purity is concerned.

Thanks largely to the work of the officials of the Department of Agriculture, whose zeal and efficiency I heartily recognise, it is coming to be more and more widely recognised that varietal purity alone is not a sufficient qualification for good seed-sets, and that the factor of health is of even greater importance. This point was demonstrated at East Craigs in August last year, when Mr. Adam Miller, the official demonstrator, stated that seed-sets having a purity of 99·5 per cent., but badly affected with virus disease, would give a very much poorer yield than a healthy stock of only ninety per cent. purity.

Recognising this, and in order to encourage the production of healthy stocks, the Department recently instituted a "stock-seed" scheme, under which a stock-seed report is issued in respect of crops which reach a standard of purity approximating 100 per cent., and which are apparently free from the degenerative or virus diseases. Potato-growers will be at one with the object in view, but one may be permitted to express a doubt as to whether the Department is proceeding on the right lines. Last year the Department's policy was to withhold their stock-seed report from stocks that did not, in the opinion of the inspector, show complete freedom from the symptoms of virus disease, notwithstanding the fact that there was not in existence a crop of certain well-known varieties that could satisfy so stringent a test. Therefore, under present regulations, interpreted in the strictest sense, there is nothing to distinguish a superlatively healthy crop of 100 per cent. purity from a crop of similar purity in which degenerating disease is rampant. This is obviously unfair, both to the producer of the healthy seed-sets and to the prospective buyer, who, so far as the Department is concerned, does not know where to apply for the healthiest stocks that are available.

It is not suggested that the "stock-seed" report should be discontinued, or that it should be granted in respect of any crop that has not attained the highest standard of health and purity, but it appears to be eminently desirable that outstandingly healthy crops, which have not quite reached the standard of perfection set by the Department, should be differentiated from crops which are seriously affected with virus disease, although 99·5 per cent. pure. Be it noted, too, that it is obviously much more difficult to determine the entire absence of the symptoms of virus disease in a growing crop than to estimate the percentage of purity. Indeed, the former is work that can be safely entrusted only to experts, and even experts have been known to differ seriously as to the presence or absence of certain diseases, such as mild mosaic. This uncertainty also condemns the perfection policy as being, at present, impracticable and futile.

In the opinion of many growers, the Department's T.S. (purity) certificate is now of very little value in transactions for the sale of seed Potatos, except in so far as it assists growers and merchants to comply with the regulations of the Seeds Act, 1920, and the Wart Disease Order, 1923. Therefore, for the further improvement of seed-sets, there is urgently required a new certificate in which the emphasis will be laid on health. The terms and conditions of such a certificate is a matter for consideration and discussion by the Department's officials and representatives of Potato-growers and merchants. Meantime, I venture to suggest :—

(1) That there be instituted a new certificate of two grades, the limits of which shall be determined by fixed percentages in (*a*) health (*i.e.*, freedom from the symptoms of severe mosaic, blackleg and leaf-roll), and (*b*) purity.

(2) That the T.S. certificate in respect of the growing crop be continued in so far as it assists growers and merchants to comply with the Department's regulations under the Wart Disease Order, etc.

Mr. Chisholm states that he has discussed this question with a well-known seed-Potato merchant, whose reputation for handling healthy seed-sets is extremely high, and here are his suggestions —

(1) That the stock-seed scheme be continued, but improved in the light of recent experience.

(2) That T.S. and Grade A certificates in respect of the growing crop be granted where the percentage of purity and freedom from blackleg, leaf-roll and apparent severe forms of mosaic exceeds an individual and cumulative percentage to be arranged.

(3) That a report, complying with the requirements of the Regulations under the Seeds Act, 1920, be issued, in which the individual and cumulative percentage of defects would be higher than in suggestion No. 2.

I place my friend's views in juxtaposition with my own, because it is manifest that, in the elaboration of an amended scheme, differences will emerge, depending to some extent upon the angle from which the question is approached. Space will not admit of details, but I hope what I have written will make Potato growers and merchants discuss the question with a vew to bringing about some reform in the Department's present scheme of inspection. *W. K.*

THE ECONOMICS OF FRUIT-GROWING IN ENGLAND.

(*concluded from p.* 127).

With regard to the old orchards, mostly planted from 1907 and onwards, I give the actual receipts per acre, from which have been deducted all marketing costs, such as commission, tolls, and transport, but not cost of production. The table was compiled from our books in the first case to ascertain, if possible, the most profitable varieties of Apples to plant on the new farm :—

Average Receipts per Acre per annum for seven years (1919-25). Bush Trees on Paradise, planted 1907.

King of the Pippins ... ... (262 bushels at 7s. 6d.)	£99	0	0
Newton Wonder ... ... (230 bushels at 8s. 0d.)	92	6	0
Quarrenden ... ... (173 bushels at 8s. 8d.)	74	14	0
Bismarck ... ... (436 bushels at 6s. 2d.)	135	8	4
Worcester Pearmain ... ... (433 bushels at 6s. 2d.)	133	0	0
Cox's Orange Pippin ... ... (81 bushels at 19s. 9d.)	75	0	0

These orchards were originally interplanted with Black Currants and Strawberries, which two crops alone recovered the total costs of establishing the permanent Apples, so that by the time the Apple trees came into bearing there was no debt.

This interplanting of temporary soft fruits is not done much in the Dominions, partly owing to incompatability of climate and the difficulty of marketing. In England, however, it is usual and most profitable. The annual cost of production after about the tenth year has been ascertained to be round about £40 per acre, 3s. per bushel, varying, of course, according to the needs of the varieties and kinds in question.

The figures are much reduced as a consequence of neglect during the war, necessitated by the lack of labour during that period. Since then there has been a steady upward trend in price and a steady increase of crop. For instance, Worcester Pearmain averaged 7s. 2d. in 1925, 7s. 6d. in 1926, and 9s. 4d. in 1927. A younger orchard of Worcester Pearmain gave an average of 10s. 9d. in 1927, and an orchard of the same variety grown as half-standards on crab stocks planted in 1913, gave an average of 10s. 3d. in 1927.

These higher prices are the direct outcome of improvements in pest control, more thinning and better marketing. Our experience is that Apples of high grade are rising in price, and those of lower grades are falling. So low in price have the lower grades become that we no longer pick them, but after the best fruit has been picked the remainder is shaken off the trees and allowed to rot on the ground. So long as £5 per ton can be got for those low grades in bags to jam factories they pay to handle—not otherwise. The prices mentioned above include all grades, from specials packed in dozens to the lowest grades sold to jam manufacturers.

Coming to the cost of establishing, so far as we have ascertained it on the new farm, we found that in the first period of about eighteen months of the plantations, *i.e.*, from November, 1925, when we took possession, until June 30, 1927, we had spent from £27 per acre in the case of the cheapest form of fruits, to £42 17s. 0d. for the dearest combination of trees and bushes. The lower cost was for forty acres of one-year-old Czar Plums interplanted with two-year-old Black Currant bushes. The higher cost was incurred in the case of thirty acres of two-year-old Cox's Orange Pippin trees interplanted with two-year-old Gooseberries. Many other combinations were planted, such as three-year-old trees with no intercrops, half-standard Plums with Raspberries between and also intermixed Plums and Apples. The average cost during the first eighteen months for 170 acres of land planted to permanent and temporary fruits was £36 2s. 0d. per acre.

For the year ending June 30, 1928, an extra capital outlay of £5 11s. 2d. per acre was incurred, making a total debt of £41 13s. 2d. per acre. From now on the interplanted soft fruits should more than balance the annual outgoings, and by the time the permanent fruit trees are in full bearing the fields should be free of debt. As an illustration of this the field planted with Plums and Raspberries has freed itself of debt with the first crop of Raspberries. The total gross return of Raspberries being two tons per acre at an average nett price of £75 per ton. Similarly, fifty-seven acres of Black Currants planted between Plums and Apples should more than pay for all outgoings next year and commence to pay off the debt of those fields. The method of accounting was as follows.

On taking over the farm, there were sundry costs, such as thrashing the late tenant's Corn, repairs to farmyards, buildings, farmhouse, cottages, sundry drains and gates. Cutting down trees and dealing with the tops, sawing wood and odd wet-day jobs, costs of implements and tools, rates—local and drainage board, tithes and Schedule A Income Tax, legal expenses and insurances, repairs to implements and general supervision. Many of these costs could well have been capitalised and spread over a period of years, but we preferred to debit each field with them at once, and they totalled £3 10s. 0d. per acre. Secondly, nearly everything is done by piecework. The farm is laid out for tractor cultivation at least one way. No preliminary manuring is done except the ploughing in of Mustard. Every July this is sown and ploughed in. Every tree has been mulched after planting at a total cost of ½d. per tree. Nearly all carting is done by tractor haulage. A rent charge of £1 per acre has been debited annually and five per cent. interest charged on all capital outlay. No provision has as yet been made for repayment of capital. This will be commenced so soon as the revenue assumes reasonable proportions. Everything has been designed to reduce costs to the lowest level consistent with efficiency. The total staff on the 275 acres (all except thirty acres being planted) is ten men and lads, augmented in spring and summer by women for hoeing. Normally, cultivation is done with two tractors (one part time) and one horse.

I have nearly come to my time limit and have not yet touched upon fruits other than Apples, but the next most important fruit is the Plum. In this case we have little to fear from foreign countries. Such as come are inferior varieties, like the French Violets and German Switchens. The canning industry is taking Plums off our markets in ever-increasing quantities. The cost of production is less than Apples, as they rarely need spraying more than once in winter. The crop is packed straight from the tree and Plums come into bearing by the fifth year and are in full crop by the seventh. Pears are not so generally grown as Apples and Plums. The earlier varieties are more profitable than the later ones in view of the heavy importations of excellent quality Pears from California and Oregon. Cherries are rapidly increasing in acreage, mostly in Kent and Worcester. Now that the import of Cherries from France is so restricted on account of the Cherry fruit-fly maggot, the future of English Cherries is much brighter. It is a crop that very many grass farms could grow without any outlay beyond the price of the trees and stakes. Grass under Cherries must be fed regularly, preferably by sheep. Cherries come into bearing about the seventh year and continue in profit for perhaps another fifty years. Pears, Plums and Cherries may be interplanted with soft fruits in their earlier years, the latter being capable of freeing the land of initial capital outlay long before they are worn out. The greatest pull English growers have over Dominion and foreign Apple growers is this ability to cover the cost of establishing orchards quickly, but it must be conceded that Apples in Canada and the States come into bearing sooner than ours do owing to their quicker growth in their earlier years. Black Currants are the cheapest form of undercrop but have a short life. Raspberries come next, with a life of about fifteen years. Red Currants and Gooseberries have the longest life, often remaining profitable for nearly thirty years.

The quickest return is to be got from Strawberries. They come into bearing their second summer, and give three crops before needing removal. The cost of establishing a Strawberry plantation is about £40 per acre, and owing to the very high prices now obtaining are quite the most profitable soft fruit crop.

Fruit Soils.

Such figures for Apples as I have given are obtainable from any light soil in the south of England, preferably a valley gravel, above the frost line, and preferably on a north or east aspect. As regards Pears and Plums, heavier soils are suitable, provided they are perfectly drained. Impervious sub-soils are anathema to fruit trees and mean a short life. However poor in texture a gravel may be, however coarse its particles may be, provided it is deep and naturally drained it will produce the most regular crops. The Essex Valley gravels, with their mixture of finer particles of clay between the stones, form the finest soils for all forms of fruit. It is being found, however, that fruits will succeed on a great variety of soils, provided the drainage is perfect and they are high enough out of the frost line. These are the predominating factors in the success of fruits. Most other soils in such a condition and position will, however, grow fruits profitably.

One other factor looms largely in the balance sheet of a fruit farm, and that is *strain*. It is being found with fruit as with live stock, names of varieties or breeds mean much less than the strain from which they are bred. Owing to the habit of fruit trees "sporting," various undesirable strains have been distributed. It is imperative that the source of propagation be examined carefully as to purity, vigour and productiveness. A buyer of fruit trees should demand to see the parent trees or bushes from which young stock is propagated and satisfy himself that the strain is a good one. The rapid decline in the production of Strawberries and

---

* A Lecture delivered by Mr. W. P. Seabrook, of Chelmsford, at a meeting of The Farmers' Club, held at the Royal Society of Arts, Adelphi, W.C.2, on Monday, February 4, 1929.

Raspberries in particular is very largely due to propagation from worn-out strains, and also depends upon the proportion of virus diseases such as mosaic in Raspberries and reversion in Black Currants. These incurable diseases can only be avoided by rigorous selection and, as in the case of cancer in the human system, can only be eradicated by removal. There is no cure.

Summing Up.

The essential requirements for success in fruit-growing are, after all, similar to those for most other products. Well-drained soil, comparative freedom from frost, careful selection of strain to start with, control of pests and diseases, and, above all, intelligent presentation to the buyer. The production of a good sample is the first need, and, thanks to modern research, this is easier now than ever before. The careful picking, grading and packing, combined with scientific marketing, is the next need. Low grades will not become high grades by careful grading and packing, but high grades will make very much higher prices when properly handled for sale. Low grades must gradually be eliminated and must disappear from our open markets.

The small grower can—and often does—produce a better sample and pack it better than his large neighbour. His cost of production may be higher, but the National Mark scheme of marketing will put him on the same footing as his bigger neighbour and enable him to overcome the drawbacks incidental to his smaller volume and lack of continuity of supplies. Otherwise he must adopt co-operative or collective selling, so that the volume of produce is enough to bear the costs of organised marketing.

Example of Average Annual Cost of Production of Apples.

(Per acre of 200 trees, bushes on Paradise, tenth year onwards, assuming cost of establishing has been defrayed by interplanted soft fruits.)

	£	s.	d.
Rent	2	0	0
Pruning at 3d.	2	10	0
Spraying—			
Tar oils at 6d.	5	0	0
3 lime sul. lead at 3d.	7	10	0
1 ploughing		9	0
3 cultivations		6	0
Brushing grass	1	0	0
Thinning fruit at 1½d. (say 300 bushels)	1	5	0
Picking at 2d.	2	10	0
Carting		10	0
Packing and Carriage	15	0	0
Manure—2 cwt. nitrate of soda ...	1	0	0
2 cwt. potash	1	0	0
	£40	0	0

LAW NOTES.

MARKET GARDENERS v. TOWN COUNCIL.

Messrs. J. and R. Ferguson, Market Gardeners, Chattan Drive, Nairn, raised an action in the Court of Session, Edinburgh, some weeks ago against the Town Council of Nairn, claiming £3,615 damages for an alleged breach of undertaking contained in a letter dated 1921, by which the defenders undertook to reinstate, to the satisfaction of a partner in the pursuers' firm, the water supply to the nursery and market garden carried on by the pursuers at Nairn. The summons also contained a conclusion for implement of the obligation, or alternatively, for payment of £150.

When the case was about to go for proof before Lord Pitman, Mr. J. L. Wark, K.C., Senior Counsel for defenders, intimated to His Lordship that he and Mr. Macgregor Mitchell, K.C., Senior Counsel for pursuers, had been able to arrange terms of settlement satisfactory to both parties. On the one hand, the defenders got out of a troublesome litigation, and on the other the pursuers would have their water supply for their garden in a shape satisfactory to them. While the terms of settlement have not been actually disclosed, it is understood that they included a payment of £350 to pursuers.

MARKET FRUIT GARDEN.

January, in my district, was a particularly favourable month for work on the fruit farm. With a rainfall of only 1·33 inch, it was a dry month, in marked contrast to January, 1928, when there were 4·26 inches of rain. This made all the difference to progress with winter spraying, particularly as there was remarkably little wind. Most of the spraying has now been done, and on only one occasion did rain fall before the wash had dried on the trees. Last year it was the rule rather than the exception for rain to follow in less than twenty-four hours after spraying. The makers of tar-distillate washes advise that no spraying should be done in frosty weather. It is, however, almost impossible to avoid this. One cannot, of course, spray while it is actually freezing; but one must take advantage of the none too numerous fine days that occur during winter, and these are generally followed by frost at night. If frost occurs before the trees have dried, the wash freezes on them; but I have not found that this does any harm or spoils the result.

Although it has not been a hard winter, fruit trees and bushes are backward. Buds do not appear to have made the slightest movement. The pistillate flowers of Cob Nuts generally appear before the end of January; but this year none could be found at that time. It is to be hoped that this means that there will be a late flowering period, usually a preliminary to a good fruit season. I have always noticed that, when the trees hold their leaves late in autumn, as they did last year, they make a late start in the following spring, no matter whether the winter be mild or severe. It seems that they take a resting period of a certain length, and that this is not varied to any extent by the nature of the winter weather.

Control of Growth and Bearing.

Fruit-growers have always desired to gain as much control as possible over the growth and bearing of their trees. At one time, in private gardens, root-pruning and even transplanting were frequently adopted as a means to this end. With present-day knowledge of dwarfing stocks and the influence of more moderate and sensible methods of pruning the head, I imagine that these laborious practices have largely gone out of use. For the commercial grower they were seldom possible, owing to the expense involved. Other means had to be sought for controlling growth and bringing the tree into the bearing habit. Just now growers seem to be striving after these results, and after the production of large and highly-coloured fruits which usually accompany them, by means of several interesting methods.

In the Wisbech district, where fruit trees make very free growth and are somewhat slow to come into bearing, there is a great revival of interest in the old practice of bark-ringing. The ringing, usually of branches rather than of the main stem, is done round about the blossoming period. As a result, there is a reduction of growth and an accumulation of carbohydrates in the portion of the branch above the ring, leading to the formation of fruit buds during the season in which the operation is performed, and the production of fruits in the year following. All gardeners have seen similar results following the partial ringing of a branch by canker. Investigations at Long Ashton have shown that ringing is valuable as a temporary expedient for use on vigorous, over-vegetative trees which, because of their excessive growth, do not form flower buds in sufficient quantity. It may be considered, in fact, to be a substitute for root-pruning, suitable for application in similar circumstances.

Whether this method can be utilised continually, as part of the ordinary routine of fruit culture, as is being done in some places in the eastern counties, remains to be seen. One grower has carried out the practice for eight years, apparently re-opening the rings each spring. It should be explained, however, that the method of ringing followed in the eastern counties is not the same as that tried at Long Ashton. Instead of removing a complete girdle of bark from the branch or stem, two half rings are removed, on opposite sides, about three-quarters-of-an-inch wide and four to six inches apart. This probably renders the ringing less dangerous than complete girdling. The wounds are painted or tarred to hinder the entrance of disease.

An Intensive System.

A more ambitious method of control is the intensive system of fruit culture devised by Mr. A. H. Lees and described by him in the issues of *The Gardeners' Chronicle* dated May 12 and 19, 1928. Apples are planted as maidens on Type II Paradise stock, usually three feet by six feet apart. The aim is to form trees which might be described as coming between single cordons and dwarf pyramids. Perhaps they are more clearly defined as self-supporting cordons with radiating laterals about eighteen inches long. In order to secure these laterals just where they are wanted, knife-edge ringing is practised freely on the main stem. Sub-laterals are converted into fruit spurs by the annual use of Lorette summer pruning. A few years after planting, a further means of controlling growth is introduced in the form of a cover crop of Red Clover. By this system the ground is thickly populated with trees which have a larger bearing area than cordons and are free from the need for expensive supporting fences. The trees come into bearing quickly and carry fruits of fine colour.

The simplest and most obvious way in which to control growth and secure early bearing is to plant trees on a dwarfing stock. Some commercial growers now possess young plantations of Apples, mainly Cox's Orange Pippin, on Malling No. IX stock (Jaune de Metz Paradise). It will be interesting to see whether these will not give as good results as Mr. Lees' trees with considerably less trouble. Except on poor soils, where this stock is too dwarfing in effect, it gives most attractive little trees which often begin to bear in the third year after planting, and subsequently carry heavy crops of very large Apples.

Grassed Orchards.

Finally, we come to grassing down as a means of checking growth, bringing the trees into bearing, and producing fruits of high colour. I believe that much will be heard about this method in the near future, for research workers are beginning to explore its possibilities. Grass orchards of standard trees, in which the herbage is kept short and the land manured by grazing stock, are, of course, familiar to every one. Plantations in which the grass is mown and used as a mulch, and feeding done by the use of chemical fertilisers, are another matter altogether, and should be more under the grower's control. After having tried this system for ten years, I feel that I am only just beginning to know something about it. The effect of grassing down is very similar to that of root-pruning. Over-luxurious trees are checked in growth and quickly thrown into bearing. In time the trees will show symptoms of severe nitrogen starvation unless steps are taken to prevent this. Evidently feeding has to be much more generous than I used to imagine. When the problem of manuring has been solved, I believe that the use of grass in orchards will become recognised as one of the best means of producing fruits of highly saleable quality.

A New Winter Wash.

I am finishing my winter spraying with a proprietary wash made in accordance with the Long Ashton formula from highly soluble tar-distillate. The result cannot be ascertained until the summer, but I am very favourably impressed with the wash at the time of application. The sprayers find that it covers the trees more easily than the older type of tar-distillate wash, and that it does not burn their faces. While it cleans the trees very well it does not burn the grass or other vegetation under them to anything like the same extent, owing, no doubt, to the exclusion of tar acids. Other virtues are that it dries quickly and does not coat the sprayer, tank or pipes with tarry matter. Altogether, I feel that it should be a safer wash to use on the trees year after year.
Market Grower.

VEGETABLE GARDEN.

THE LEEK.

THE Leek (Allium Porrum) is a wholesome vegetable which has been grown in this country since very early times, particularly in the north and in Scotland and Wales, where it is highly appreciated, probably because of its extreme hardiness. Leeks withstand the severest weather without harm, and may remain in the open ground until required without deteriorating.

The Leek is stated to be a native of Switzerland but, although it is the ancient badge worn by Welshmen on St. David's Day, it is doubtful if anyone really knows its origin. It may have come from Egypt, where it was known many thousands of years ago. One writer thinks it originated in Druidic times, and that the plant was a symbol of Cendven, the British Ceres. Others maintain that it was the sign under which the Welsh gained a victory over the Saxons, St. David having advised them to assume the badge. Certain it is that the Rose, Shamrock and Thistle are not more honoured in the countries which have adopted them as emblems, than is this odorous potherb of which an historian has written:—

> " I love the Leek above all herbs and flowers ;
> When first we wore the Leek the field was ours ;
> The Leek is white and green, whereby is meant
> That Britons are both stout and eminent ;
> Next to the Lion, and the Unicorn,
> The Leek's the fairest emblem that is worn."

The Leek is a true biennial, that is, it continues its growth for a whole year before it prepares to flower and produce its seeds ; thus its season of supply extends throughout the greater part of the year, and by using the summer crop in a small state, it serves as a potherb for flavouring purposes throughout the year. It will grow in any well-worked soil but, like most other vegetables, responds to liberal treatment, when it attains a great size. Sowings may be made in the open ground in well-prepared seed-beds from February to April, but for most gardens a sowing made about the middle of March will suffice to provide for two or three plantations.

Where very early supplies are required, however, a few seeds may be sown in January on a gentle hot-bed, the seedlings being grown on under well-ventilated conditions and gradually hardened off for planting out about the end of March.

To obtain fine Leeks many growers make trenches for them, in the same way as for Celery, and on light soils this will be found a convenient method to facilitate the application of water, but it is not essential, and excellent produce may be obtained by growing them in drills. These should be drawn to a depth of five or six inches, about twenty inches apart, placing the plants ten inches apart in the drills. The drills afford some measure of protection to the plants in the early stages of growth, and the frequent hoeings, practised during the growing season, gradually fill the drills and blanch the necks of the Leeks. Later on further earthings-up may be made to extend the length of the blanched portion, and by this method long, perfectly blanched Leeks of the highest quality may be obtained at considerably less cost in labour than is entailed in preparing trenches.

A use for Leeks, which was more widely practised in earlier times than it is to-day, is the production of bulbs. This is effected by leaving plants in the spring, when they begin to produce flower spikes, and removing the flower-buds as they appear ; by this means the formation of bulbs at the base of the neck is induced, and these constitute a delicious vegetable of the Onion-flavoured class ; our forbears, who had a much more limited choice of vegetables than we have at the present day, used to consider these bulbs an uncommon luxury. *W. A.*

SOCIETIES.

CARDIFF GARDENERS'.

THE annual dinner of the above Association was held recently at the Queen's Hotel, Cardiff. Douglas Cory, Esq., presided, and an excellent repast was partaken of by a large number of members and friends, who were afterwards entertained to a first-class concert.

At the fortnightly meeting of the Association held at the end of January, the lecturer for the evening was Mr. J. T. Smith, of Duffren Gardens, his subject being " Trees and Shrubs." Mr. Smith dealt with his subject in an interesting manner, and illustrated it with numerous specimens. He spoke chiefly of variegated shrubs which are useful for brightening the garden during the dull days of winter, and described many in detail, including the uncommon forms of Aucubas, Elaeagnus, Osmanthuses, Taxuses, Andromedas, Pittosporums, Daphnes, Trochodendrons, Viburnums, Loniceras, Ligustrums, Skimmias, Griselinias, Hypericums, Ruscus, Grevilleas, Phlomis and Cotoneasters. He also mentioned such well-known winter-flowering plants as Garrya elliptica, Erica lusitanica and Hamamelis mollis, and spoke of the value of the variegated Conifers. His advice with regard to preparing the soil and transplanting trees and shrubs was very sound, while he also discussed tree surgery.

The competitions for the best decorative plant, and the best pot of bulbs, resulted in Mr. F. FOLK securing first prize, and Mr. L. GIBBS the second, in the former class, and Mr. E. HANN, first, and Mr. BENNETT, second, for the best pot of bulbs. Numerous points were awarded for non-competitive displays.

NEWCASTLE HORTICULTURAL.

THE January meeting of the above Society attracted a very large attendance, quite the largest for many months. The monthly competitions were very interesting, and some fine exhibits were shown. The chief prize-winners were Messrs. W. BRIGHT, T. MILLS and W. HOWARD, for Cyclamens ; Mr. J. DORAN, for Tulips ; Messrs. W. BRIGHT and T. MILLS, for ladies' sprays and gentlemen's buttonholes ; Mr. Y. R. RHODES, for Dracaena pendula ; Mr. J. DORAN, for Brussels Sprouts ; and Messrs. J. T. HALL and J. YOUNG, for Leeks. For a fine collection of Leeks, Mr. HALL gained the special monthly prize. Mr. W. WOOD was awarded the prize, given by Mrs. Hill, for the best exhibit in the show—a splendid collection of Roman Hyacinths. The feature of the evening was an instructive and interesting lecture, given by Merion Thomas, M.A., of Armstrong College, on " Plants and Air." It was illustrated by a fine collection of lantern slides.

PROFESSIONAL GARDENERS'.

GOOD progress continues to be made in the organisation of the professional gardeners of the country, and there was a large attendance at the eighth annual dinner of the Professional Gardeners' Association, which took place at its headquarters, the Guildford Hotel, Leeds, on Saturday, February 2. Mr. J. T. McCormack, President of the Association, occupied the chair, and prominent members and guests present included Mr. Harold Mitchell, President of the Bradford and District Branch ; Mr. C. H. Gartery, Huddersfield ; Mr. W. Wells, Harrogate ; Mr. F. W. Capp, Wakefield ; Mr. F. Edwards, Leeds ; and Mr. E. J. M. Edelsten, Pickering.

The Association has a membership of about 3,000, and branches have been formed at Baildon, Bradford, Harrogate and Huddersfield, while others are in process of formation at Newcastle, Sheffield and Birmingham. The Association is run on a non-union and non-political basis, its most prominent feature at present being its benevolent fund.

Mr. McCormack, in proposing the toast of the " Guests and Delegates," said the Association sought to foster amicable relations between employers and employees. He pointed out that Mr. Mitchell, the President of the Bradford branch, is an employer of professional gardeners, and, although not a professional gardener himself, is a keen horticulturist, and an active supporter of the Association. He also thanked members of the trade for their co-operation. Mr. Mitchell, responding, said that when two men worked together, although one paid wages to the other, if they could not be friends they had better part. The Association was doing extraordinarily good work, and professional gardeners who held aloof from it would lose a great many benefits. He suggested that some of the senior members should help the younger ones by means of lectures and discussions on gardening topics. Mr. Capp, one of the founders of the Association, and its first Organising Secretary, presented to the Association a framed portrait of himself, to be hung in its headquarters.

An attractive programme of music was provided.

GUILDFORD CHRYSANTHEMUM.

THE Annual Meeting of this Society was held at the end of January. The President, F. F. Smallpeice, Esq., occupied the chair.

The Secretary, Mr. Walter Miles, presented the thirty-sixth Annual Report, which dealt chiefly the annual show held last November. This was with declared to be a record from all points of view, the entries, 290 in all, being sixty-one more than in 1927. The exhibits were of a high standard all round, and the appreciation of the public was evidenced by the large attendance on both days. The report closed with an appeal for new subscribers, or further donations.

Mr. W. T. Patrick, J.P., submitted the financial statement. The total income, including a balance of £35 6s. 3d. brought forward, amounted to £209 3s. 9d. The expenses were £183 8s. 5d., being about £31 more than last year—without a corresponding increase in the receipts—which reduced the balance in hand to £25 15s. 4d.—a drop of about £10 on the year's working. This was attributed, for the most part, to a more liberal prize list.

Mr. Smallpeice was re-elected President on the motion of Mr. Joy. In accepting, Mr. Smallpeice said he appreciated the honour again conferred upon him. Mr. Patrick and Mr. Miles were re-elected to their respective offices, and the whole of the Committee was re-elected *en bloc.*

Mr. Patrick proposed a vote of thanks to Mr. Smallpeice, and expressed his pleasure that the President was able to be with them again after his long and serious illness last year.

It was decided to hold the annual show on Wednesday and Thursday, October 30 and 31, next.

GUILDFORD GARDENERS'.

Two items of especial interest marked the activities of this Society during January, the first being a very successful whist-drive on the 23rd, and the second, a social gathering on the 30th.

While such meetings are admittedly of a festive character, they yet have a serious side—they contribute to, and cement the feeling of fellowship that prevails, and at the same time serve to augment the funds whereby the more serious work is carried on.

For the whist drive Mr. A. J. Joy was Chairman of the Committee, and proved to be a genial M.C. During an interval, the President, Alderman W. T. Patrick, J.P., gave a brief address in which he made the gratifying announcement that Mr. Pettit, the Hon. Show Secretary, was receiving great encouragement in his preliminary work for the next show ; The Duke of Sutherland, Sutton Place ; Mr. Lloyd George, M.P., who has a residence at Churt, Surrey ; and Mr. Jeudwine, of Tangley Place, had promised cups, while the Earl of Onslow, Clandon Park, who has consented to become a Vice-President, had promised a Silver Medal.

In addition to the social functions, a meeting of the Association was held on January 22, when a visit was received from Mr. Lavender, of Messrs. James Carter and Co., who read an interesting paper on "Annuals." The next lecture will be by Mr. W. Auton, on March 5.

ROYAL GARDENERS' ORPHAN FUND.

THE severe weather may have been partly responsible for the small attendance at the Annual Meeting of the subscribers to this Charity, held in the Royal Horticultural Hall, on Wednesday, February 13. Probably the absence of so many members of the Committee and subscribers was due chiefly to the fact that there was no competition for the benefits of the Fund, and also, that the Charity is in a very excellent position financially.

Mr. David Ingamells presided, and was supported by Mr. George Monro and Mr. Peter R. Barr, others present being Mr. J. F. McLeod, Mr. J. M. Bridgeford, Mr. R. B. Leach, Mr. J. Wort, Mr. D. Swain, Mr. W. F. Giles, Mr. Charles H. Curtis, Mr. C. Rayner, Mr. Alesworth and Mr. A. C. Bartlett, Secretary.

The Report of the Committee for 1928 was read by the Secretary, and the accounts for the year were presented by Mr. Peter R. Barr, the Hon. Auditor, who was subsequently re-elected to that position.

EXTRACTS FROM THE REPORT FOR 1928.

Thanks to the continued support of the subscribers and donors, The Royal Gardeners' Orphan Fund has been enabled to continue its work of providing allowances towards the maintenance of the orphans of gardeners. and others in allied callings, who have been so unfortunate as to be deprived of the bread-winner of the family while they are on the threshold of life. Continued support has made it possible, not only to pay the regular allowances, but to extend them in several special instances where it has been evident that extended education would greatly improve the children's prospects by better equipping them for their life's work and, through them, benefit the country generally.

For several years the possibility of recommending an increase in the weekly payments to the orphans has engaged your Committee's attention, but they regret to report that, without a greater income, it is not yet possible to recommend any increase in the weekly allowances. The total receipts from all sources during the past year, including the balance from 1927, amounted to £3,158 1s. 6d. This sum includes a legacy from the late Mr. Will Tayler, and £35 6s. 0d,. the result of the half-crown appeal made by the late Mr. H. J. Jones. The kindly thought of these donors, who for many years were regular subscribers to the Fund, is greatly appreciated. In continuance of their financial policy, the Committee have made a further contribution towards the restoration of the Invested Funds to their pre-war position. The Annual Festival Dinner, held at the Hotel Victoria last May, was very successful, and the means of materially increasing the income of the Fund. Grateful thanks are returned to Gerald W. E. Loder, Esq., who presided and made a generous donation of one hundred guineas, and obtained a similar sum from a donor who prefers to remain anonymous. To all other donors grateful thanks are offered, and particularly to Mr. David Ingamells, who collected over £280; to Mr. Harry Miles and his helpers, who decorated the tables so tastefully; to the Stewards, and to all who contributed to the success of the Annual Festival Dinner.

The Committee announces that Samuel Wallrock, Esq., The Manor House, Stanmore, Hertfordshire, has kindly promised to preside at the next Festival Dinner, which has been arranged for May 15, 1929.

The Committee acknowledge with heartiest thanks, the valued contributions from the following gardening associations, and desire to offer the Fund's hearty thanks to the members and officials whose ready help made the contributions possible: The Royal Caledonian Horticultural Society, Altrincham and District Gardeners' Improvement Society, Sandringham Estate Cottage Horticultural Society, Southport Flower Show, Professional Gardeners' Lodge, Croydon and District Horticultural Mutual Improvement Society, Brighton, Hove and Sussex Horticultural Society, Newbury and District Gardeners' Association, Parkstone Gardeners' Association, Leeds Paxton Society, Isle of Wight Horticultural Society, Wimbledon Gardeners' Mutual Improvement Society, Bournemouth and District Gardeners' Mutual Society, Sevenoaks Gardeners' Society. West Kent Chrysanthemum Society, and Sutton Coldfield Gardeners' Society. Considerable amounts were also collected by Mr. T. H. Cook, of the Royal Gardens, Sandringham; Mr. G. J. Weston, Chatsworth Gardens, Bakewell; *The Gardeners' Chronicle*; Mr. Joseph Lytle, Garden Supplies Co., Liverpool; Mr. T. Pateman. Brocket Hall Gardens, Hatfield; Mr. Wm. Rowe, Squerryes Court Gardens, Westerham; Mr. W. Auton, Woking; Mr. C. Nippard, Bournemouth; Mr. A. Nicholl, Hursley Park Gardens, Winchester; Mr. A. H. Fulker, Reading; Mr. Wm. Austin (of Glasgow), Harrogate; and Messrs. Wm. Thomson and Sons, Clovenfords, chiefly by means of concerts and other entertainments.

It is with sincere and deep regret the Committee record the deaths, since the last Annual Meeting, of several old and greatly valued supporters of the Fund. The Rt. Hon. Lord Lambourne presided at the Festival Dinner of 1913, and as a Vice-President was always ready and willing to do everything possible to aid the Fund. Mr. H. J. Jones first became a member of your Committee in 1895, and always had the welfare of the Fund deeply at heart. The result of Mr. Jones' last appeal for the orphans has already been recorded. Mr. C. Dixon, whose death the Fund also deplores, was a valued member of Committee for a number of years; while in the death of Mr. Graeme A. Whitelaw, the Fund has lost a generous annual subscriber. The members of Committee who retire by rotation and who offer themselves for re-election are Mr. D. Campbell, Mr. Alfred Dawkins, Mr. J. E. Dixon, Mr. R. Findlay, Mr. W. J. Penton and Mr. F. C. Stainsby. For the two vacancies, your Committee wish to nominate Mr. R. C. Pulling, of Messrs. H. J. Jones, Ltd., and Mr. F. Moon, Ackwyeron Gardens, Wimbledon Park.

THE ROYAL GARDENERS' ORPHAN FUND

PETER R. BARR,
RICHARD A. WITTY, } *Auditors.*
Incorporated Accountant

February 8, 1929.

*Of this amount £205 9s. 0d. is required to meet payment of the Children's Allowances, on January 1st, 1929.

Mr. P. R. Barr pointed out that the nominal value of the invested funds was now £14,335 6s. 9d., as compared with £13,329 1s. 5d. in 1914; and the dividends now amounted to £496 15s. 0d., as against the pre-war sum of £397 1s. 5d. From this he argued that the grants might very well be increased.

The Chairman moved the adoption of the Report and Audited Accounts. The motion was seconded by Mr. C. H. Curtis, who said that all associated with the Fund would be glad to learn that the Committee had been able to replace the investments realised during the war, and had been able to increase the income from dividends. He regretted the meagre attendances due, perhaps, to the happy state of the finances which enabled the Committee to recommend the placing of all applicants on the Fund without a competitive election. He had previously, urged an increase of benefits, and after Mr. Barr's statement, he felt there was no longer any need to withhold an increase on financial grounds. The motion was carried.

Mr. Barr then proposed that the weekly grants to Orphans should be raised to 7s. 6d., and that the Committee be empowered to take such steps as are necessary to give effect to the proposal (a General Meeting will be necessary as a rule is affected). Mr. C. H. Curtis seconded the proposal, which received unanimous assent.

Mr. George Monro moved a vote of thanks to Mr. Gerald W. E. Loder, and congratulations on his election to the Presidency of the Royal Horticultural Society. This was carried, as was the proposal of Mr. Giles, that Mr. Edward Sherwood be re-elected Treasurer. The proposals of Mr. Wort and Mr. Leach, regarding the re-election of retiring members of Committee and the election of the two new members recommended in the Report, also received assent, while Mr. A. C. Bartlett's re-appointment as Secretary, gave Mr. Ingamells and Mr. Monro the opportunity to say kind things about his work, and these kindly remarks were heartily endorsed by all present. No less hearty were the thanks accorded the Chairman, who presides so genially and works so tremendously hard on behalf of the Royal Gardeners' Orphan Fund, which has its headquarters at 19, Bedford Chambers, Covent. Garden, London, W.C.2.

SALISBURY GARDENERS'.

ON February 6, in connection with the Salisbury Gardeners' Society, an important lecture was delivered by Mr. W. H. Turner, B.Sc., Technical Advisor to Messrs. George Monro, Ltd., on the particular values of certain fertilisers, and the sterilising of soil. The lecture room at the White Hart Hotel was well filled, many friends from Andover and other districts being present.

The lecturer mentioned that the practice of fertilising the soil was nearly as old as cultivation. About the year 1800, important scientific discoveries took place, and it was found that plants needed carbon, sulphur, phosphates, potash and nitrogen to sustain growth. Nitrogen was a most important plant food for the Cabbage family, while phosphates were particularly useful in the cultivation of root crops, and the potash for fruits. As regards organic manures, he was of the opinion that farmyard manure was far and away the best, particularly on heavy soils.

Proceeding, the lecturer gave some very interesting results from various trials that he had carried out, proving beyond doubt the wonderful strides that had been made through scientific research during the last century. With regard to partial soil sterilisation by the modern steam process, the lecturer stated that the soil contained good and bad bacteria, and partial-sterilisation killed, to a very great extent, injurious bacteria, and so naturally purified the soil. It was the only sure method of killing fungus and other diseases. Very useful information was imparted, which, if acted upon, would certainly improve the quantity and quality of crops.

Mr. W. F. Gullick, in proposing a vote of thanks to the lecturer, stated that this particular lecture was the two-hundred-and-fortieth delivered before the Society, and he did not remember a lecture of so technical a nature being delivered with such simplicity. They were not only indebted to the lecturer, but also to Messrs. George Monro, Ltd., for having made the lecture possible.

A remarkable collection of Potatos was exhibited by Mr. W. F. Gullick. The Chairman stated that the Potatos were grown in Fifeshire, having already been exhibited on three different occasions, and had been awarded Gold Medal. On behalf of the Society, he thanked Mr. Gullick for the trouble he had taken in procuring and staging such a comprehensive and useful collection, which gave them the right idea of the size, shape and standard of the various kinds worth growing.

PARKS AND BOTANIC GARDENS SUPERINTENDENTS.

The quarterly meeting of the North-western Branch of the Parks and Botanic Gardens Superintendents' Association was held in the Town Hall, Manchester, on Saturday, January 26, when there was a good attendance of members.

It was decided that the Branch Committee undertake the local arrangements to be made in connection with the Annual Conference of the Association, which will be held at Manchester in July next. It was also agreed that the annual meeting of the Branch be held in the Town Hall, Manchester, on Saturday, April 27.

Following the meeting, Mr. M. Morgan, Superintendent of Parks, Crewe, gave an address on "Some Experiences of a Parks Superintendent." Mr. W. W. Pettigrew, President of the Association, occupied the chair. In his address, Mr. Morgan emphasised the desirability of encouraging in the younger generation a love of nature and respect for public property. A vote of thanks was unanimously accorded to Mr. Morgan for his interesting lecture.

KINGSTON AND SURBITON CHRYSANTHEMUM.

The Annual General Meeting of this Society was held on Wednesday, January 30. In the absence of the President, Mr. H. C. Gardner was voted to the chair. The Report and Balance Sheet for 1928 were read and considered very satisfactory; a balance of £18 11s. 10d. was carried forward. The President, F. G. Wigley, Esq., was again elected, as was the Secretary, Mr. W. H. Divers; a few new members were added to the Committee, and Mr. H. Thomas was elected Assistant Secretary. A series of lectures has been held in Kingston in order to spread a better knowledge of horticulture in the district; these have been the means of adding many members to the Society, and they are being continued.

ELGIN HORTICULTURAL.

The Annual Meeting of this Society was held in Elgin, Lord Provost Wittet, the Honorary President, taking the chair. Mr. Mann, Secretary, submitted the Annual Report and Balance Sheet, which showed that last year's two-days' show was eminently successful, and that the surplus balance in hand for the year was £79 9s. 1d. The Chairman, in moving the adoption of the report and accounts, paid a high tribute to the organisers of last year's show, and stated that, although the Society was not out to make money, but rather to advance the science of horticulture in and around Morayshire, it was very satisfactory to have a nest egg. The Report and Statement of Accounts were unanimously approved.

Officers were then appointed, Lord Provost Wittet again accepting the post of Honorary President, although he had been strongly advised to give up his public appointments. Mr. George Milne, Newmill, Elgin, was elected President; Mr. John Coutts, Rosefield, and Mr. L. C. O. Smith, Vice-Presidents; and Mr. T. L. Mann was enthusiastically re-elected Hon. Secretary. Warm tribute was paid to Mr. Mann's fine work on behalf of the Society, and it was unanimously agreed to increase his honorarium by £10. The Council of both amateur and professional gardeners was also re-elected, and it was agreed that the annual show this year be held on Wednesday and Thursday, August 21 and 22. The question of a one-day or two-day show was mooted, but as the second day of the show last year more than paid for itself, it was resolved to continue the two-day arrangement. The proposal that the Society should purchase outright the material for the staging at their shows, and not have to pay a yearly fee for hiring it, was adopted.

LONDON AND SOUTH OF ENGLAND VIOLA AND PANSY.

At the Annual General Meeting of the above Society, held recently, the Report showed a satisfactory year's working. Mr. Eric Holroyd was re-elected President, and Mr. John H. Little, Brent Tor, Brentwood Road, Romford, Hon. Secretary and Treasurer.

The third Annual Show will be held at the Royal Horticultural Society's New Hall, Westminster, on July 16, 1929, when classes will be again provided for Violas (exhibition and bedding varieties), Violettas, Viola species and Pansies.

The Society will offer, for the first time, Certificates for new varieties of Violas and Pansies. The Secretary will be pleased to furnish any interested persons with particulars of the Society.

CROYDON HORTICULTURAL.

There was a large attendance of members at the recent meeting of this Society at the Y.M.C.A. Hall, North End, Croydon, when Mr. H. S. Jolly, of Kenley, gave an interesting lecture on "A Few Plants and their Natural Habitats.''

He dealt with a number of the native plants of Madeira—Gardenias, Camellias and Bouvardias—and then reviewed the flora of the Cape Peninsula. Numerous plants from India were described, and the lecture was concluded with a brief survey of Holland and its horticultural activities.

Obituary.

Georges Couderc.—The French agricultural journals have just announced the death, at an advanced age, of Georges Couderc, the celebrated Grape hybridist, to whom French viticulture is indebted, in large measure, for its prosperity. From the time of the first invasion of Phylloxera, which menaced with ruin all the French vines attacked by this terrible scourge, Couderc realised—being one of the first to do so—all that might be accomplished for the restoration of the ravaged vineyards, either by crossing American species with French varieties so as to combine the quality of the latter with the resistance of the former to the attacks of the insect, or in crossing together the various American types in order to obtain stocks adapted to different soils and climates. Couderc was a scientific man, and his work was conducted methodically. Literally thousands of crosses were effected on his beautiful estate of Aubenas (Ardèche), at the foot of the Cevennes Mountains, in the south of France. Extremely important results were obtained as a consequence of this work, and the Couderc hybrids, most of them designated simply by a number, now bulk largely in the restored French vineyards, either in the form of stocks, or as "direct producers," *i.e.*, vines which are capable of producing Grapes from which wine of quality can be made. Couderc's activities did not, however, cease with his work on the Vine; he was intensely interested in the cultivation of exotic fruit trees, and had formed a large collection. He was greatly interested in the improvement of the Orange and other Citrus trees, and had endeavoured to collect, at Aubenas, the largest possible number of types. The problem he had set himself was to obtain Oranges resistant to cold, and capable of flourishing in the open air to the same limits of climate as the Olive (see *La Revue de Botanique Appliquée et D'Agriculture Coloniale*, Paris, November, 1922). He had observed, in the hardiest members of the Japanese group of Oranges, viz., Satsuma, Unshu, etc.,—according to him, apparently hybrids of Citrus japonica and C. Aurantium—very considerable individual differences, and had been successful, by selecting resistant specimens and grafting them on the hardy Citrus triptera, in obtaining trees which were able to withstand a temperature of 14°C. below zero. He subsequently produced a number of hybrids of Satsuma, Unshu, etc., by crossing them with well-known varieties of Orange, such as Jaffa and Washington Navel. He was also interested in Pineapples, and had, in his hothouses, various seedlings of the Smooth-leaved Cayenne. Finally, towards the close of his life, the Chestnut scourge known as "ink disease," which does a great deal of damage in the south of France, occupied his attention, and he had begun a series of crosses with Japanese types considered to be resistant to infection. *A. M.*

Joseph Hoskins.—We regret to announce the death of Mr. Joseph Hoskins, at the age of seventy-five years, a landscape gardener with Messrs. Neal and Messrs. Wallace for nineteen years.

Gilbert R. Hunter.—Friends and past students of the Midland Agricultural and Dairy College, Sutton Bonington, will regret to learn that Mr. Gilbert R. Hunter, B.Sc., died, after a brief illness, at Sutton Bonington, on Sunday, February 17. He was appointed lecturer in engineering and surveying in 1923, after graduating at Edinburgh, and from the outset showed great initiative and determination. This, combined with his enthusiasm, ensured the success and development of his section of the work at the College. The late Mr. Hunter also showed a keen interest in student activities, and took a leading part in the development of the College Dramatic Society. His death will be a great loss to the College and his place difficult to fill.

Seth L. Mosley.—The death of Mr. Seth Lister Mosley, of Wasp Nest Road, Huddersfield, has removed one of the best-known residents of the borough, and a naturalist of widespread reputation. A frail man, whose life was more than once despaired of, he reached the age of eighty years—in itself a tribute to the frugal and simple mode of life which he imposed upon himself. The son of a hand-loom weaver, who afterwards became a game-keeper, Mr. S. L. Mosley was born at Lepton. His health was so poor that his total period of school life was only six months. His father became interested in taxidermy, and used to walk from Lepton to Doncaster to take lessons in the art. Mr. Mosley ascribed his love of nature and nature study to the influence of his father. Early in life he began the study of entomology, and the knowledge he acquired was so great that he was eventually selected to remodel the collection belonging to the Board of Agriculture at the Bethnal Green Museum. So well did he perform this work that he was selected to undertake a similar duty for many of the principal museums of the country, and for the museums of Melbourne and Philadelphia. Forty years ago, Mr. Mosley was appointed a botanical teacher under the Science and Art Department, and for seven years he taught voluntarily and without payment at local schools. About thirty year ago, he was appointed Curator of the Technical College Museum, and held that position for about twenty years. During his retirement he worked on an illustrated natural history of the Huddersfield district, a work which remains unfinished. For a long period he was secretary of the Huddersfield Naturalists' Society, and was a Fellow of the Entomological Society of London. He founded the Christian Nature Study Mission in 1900, and produced numbers of coloured drawings of butterflies which are considered unique. *Natural History*, which Mr. Mosley purchased in 1894, became, under his editorship, the most widely circulated organ of the kind in this country.

Mathias Ramstetter.—We regret to learn from the German horticultural press of the death of Mathias Ramstetter, a famous nurseryman of Hanover, at the age of sixty-one years. Herr Ramstetter settled in Hanover in the early nineties, where he established his business, and took from the first a prominent part of the local horticultural affairs, in which he showed himself a born organiser. Many an exhibition owed much of its success to his untiring energy and skill, and to the genial spirit which united all the sections in the horticultural trade. At the recent great Chrysanthemum exhibition in Hanover, although his strength was already failing, he made a noteworthy speech which will remain long in the minds of his hearers. His death will be a very great loss to horticulture in Hanover, and, indeed, in all Germany. The wealth of floral tributes which graced his funeral, and the concourse of friends who attended to pay their last tribute to his memory, afforded ample witness of the esteem and affection in which he was held.

W. E. Trevithick—We regret to announce the death of Mr. W. E. Trevithick, from pneumonia, on February 10, at Headfort House Gardens, Kells, Co. Meath. Mr. Trevithick was born at Helston, Cornwall, in 1858. He began his career in the gardens at Trevarno, Helston, and then went to Oleley Park, Shropshire; after some years there, he went, in 1883, to Putteridge Park, Luton. He spent two years as foreman at Wentworth Woodhouse, and four years as general foreman to Lord Wimborne, at Canford Manor, Wimborne. Mr. Trevithick was head gardener to the Marquis of Exeter at Burghley, and passed on to Gaunt's House, Wimborne, where he spent ten years as gardener to Colonel Richard Glyn. In 1912, he was appointed gardener to the Marquis of Headfort. With such wide experience as Mr. Trevithick had gained in these first-rate gardens, combined with a keen love of his work, it can be easily understood that he was a master of his craft, an expert grower of stove and greenhouse plants, and very clever at forcing flowers, fruits and vegetables. He was also an excellent botanist. Mr. Trevithick proved his adaptability early in his career at Headfort, by planting and caring for the new arboretum, a feature to which the Marquis of Headfort has devoted much energy and care. When Wilson, Farrer, Forrest and Kingdon Ward sent home seeds of their collecting, further tests of Mr. Trevithick's skill were made. Quantities of these seeds, especially Rhododendrons, reached Headfort. All of these were listed, raised, pricked-off, and finally transferred to frames by Mr. Trevithick himself. The making and stocking of the nursery from these frames was also his especial work. Many Rhododendron growers from England and Scotland have seen the results of his treatment and can testify to the excellence of the plants. The nursery plants, when big enough, were transferred to the grounds, where special preparations had to be made for them. Mr. Trevithick was a very clever propagator, succeeding with such difficult plants as Willdenowia teres, various species of Nothofagus, Eucryphia Moorei and E. Billardieri. During his service at Headfort, Mr. Trevithick staged many interesting groups of Rhododendrons, also other plants, at exhibitions of the Royal Horticultural Society of Ireland, which secured Gold Medals and many other awards. He gained the regard and confidence of Lord Headfort. The gardens and grounds of Headfort House are a memorial of good work in which the co-operation and planning of employer and gardener is evident. Mr. Trevithick's remains were followed to the churchyard in Kells by a large gathering. Lord Headfort placed a beautiful wreath on the coffin, which bore a sympathetically worded inscription to his friend. Members of his own family, the estate agent, Sir Frederick Moore, the indoor staff, the garden staff, estate workers and others, were present. There were many floral tributes. Mr. Trevithick leaves a widow who is an invalid, two sons and two daughters, for whom much sympathy is felt.

ANSWERS TO CORRESPONDENTS.

AMARYLLIS (HIPPEASTRUM) UNHEALTHY.—*M. L. F.* The leaves you sent us were badly infested with thrips and red spider, probably owing to the atmosphere in which they are growing having been kept too dry. Sponge all the leaves vigorously with a nicotine and soft-soap solution, maintain a less arid atmosphere, and turn the plants on their sides occasionally and syringe the undersides of the foliage with the above insecticide. Occasional syringings with clear water will also assist in keeping these pests in check.

ASPARAGUS PLUMOSUS DISCOLOURED.—*E. G. C.*—The plant of Asparagus plumosus is free from disease, and the dying-back of the foliage is due to unhealthy root action. The tips of many of the roots are dead, and it appears as if they have come into contact with something distasteful to them. Some alteration should be made in the compost. Make a thorough inspection of the soil to see whether there are any lumps of lime, or masses of decaying organic matter which will set up an acid medium, or ashes, which may be in contact with the roots.

CULTURE OF DIELYTRA SPECTABILIS.—*L. L.* Dielytra spectabilis is one of the easiest of subjects to force; if clumps are lifted from the open ground, potted in a moderately light, loamy compost, and placed in a glasshouse with a moderate temperature, they should soon start into growth and make useful decorative plants. In the open garden they should be grown in a cool, lightly shaded position for preference, in warm, light but rich soil. It is not difficult to establish, and when once planted may be left undisturbed for many years.

DISCOLOURED WATER IN A LILY POND.—*S. P.* If the water in the pond, and the water taken from a well beneath it, was pinkish-lilac, one could presume that it had been contaminated from the new red sandstone beneath it which is often variegated by different chemical combinations of iron; but this would not be very visible unless the well has tapped a bed of water that has stagnated for a long period, giving the iron ore time to accumulate in the water. There are chalybeate springs in the country containing various combinations of iron, but they are not highly coloured unless stagnant. You also state the water is milky, which would suggest chalk, but there is none in your district, although some might be dissolved from the concrete. It is more likely that the discoloration of the water is due to a variety of impurities in it, such as minute vegetation, animalcules, or dead organic matter. Neither dissolved chalk, limestone nor iron compounds of the more common kinds, nor dead organic matter, would be injurious to the Water Lilies. The water could be changed late in March, and the pond scrubbed out and washed, as is usually done by having a pipe in the bottom by which the water could be run away in a drain. This gets rid of the decaying vegetable matter at a time when the Lilies are resting. Large bodies of cold water are unfavourable to the Lilies when they are growing.

GARDENER'S NOTICE TO LEAVE.—*Civis.* It is always open to the employer to determine the head gardener's employment on giving him the proper notice, and it would therefore be within the power of the employer to do this if the head gardener's wife gave the employer notice determining her service as housekeeper. It does not, however, necessarily follow that the employer would take this step if properly approached.

GROWING EGG PLANTS (AUBERGINES).—*C.* Aubergines are not difficult plants to grow, provided they are kept free from insect pests. Perhaps the two most troublesome of these are red spider and white fly. The seeds should be sown in a good open compost early in March, for preference in a six-inch receptacle. When the seedlings are about three inches in height they should be potted singly into small pots, and, when they have filled these, should be transferred to six-inch pots, finally planting them in those of eight-inch size. Good results may also be obtained if they are planted out in a bed of soil. Good open loam, with some short manure or leaf mould, a little bone-meal and sharp sand added, should form a suitable compost. The size of the fruits will be improved greatly if some stimulating fertilisers are afforded the plants when several fruits have set on each. New York Purple and Long White are both good varieties to grow.

LONICERA SYRINGANTHA FAILING TO FLOWER.—*W. F. W.* The position in which your plant is growing should suit this bush Honeysuckle if the soil contains sufficient nutriment for it to make good growth. Give a mulch of well-decayed manure in May, or immediately after flowering in June, to encourage the production of new shoots on which the following year's blooms will be produced. The lilac-coloured blossoms are not always produced freely. It may be that the plants raised from seeds vary in this characteristic and, if one has a free-flowering bush, increase by cuttings or layering would be worth while.

NAMES OF PLANTS.—*S. P. S.* Acacia longifolia.—*G.* 1, Libertia paniculata; 2, Libertia formosa; 3 and 5, Helleborus colchicus varieties; 4, Helleborus niger.

NAMES OF FRUITS.—*H. J. H.* Apple Newton Wonder.—*J. P. C.* The specimen you sent was entirely out of character; send a characteristic fruit next season.

ORANGE LEAVES FALLING.—*W. W. N.* The fallen Orange leaves sent were insufficient material from which to make a diagnosis of the trouble. A small branch from which foliage is being shed should be sent. There was no sign of disease on the petiole; the scale nymphs and some red spider present should have no effect on leaf-fall. The severe pruning experienced by the plant would exercise a physiological effect, as the balance between root and stem would have been temporarily upset. The trouble may be due to poor drainage or the roots coming into contact with some material distasteful to them.

PLANT FROM AUSTRALIAN SEEDS.—*M. C.* Your plant appears to be Syncarpia laurifolia, an Australian plant belonging to the Natural Order Myrtaceae. This becomes a large tree, and has been planted extensively in India and California. We cannot, however, be certain of the identity of your plant, as a young seedling differs somewhat from the adult plant. It will not grow out-of-doors in this country, as it requires a greenhouse temperature,—an average of 40° to 50°; given such conditions you should be able to grow it in a large pot or tub.

SODIUM CHLORATE AS A WEED-KILLER.—*E. C. V.* Potassium chlorate ($KClO_3$) is well-known, but we cannot find any reference to sodium chlorate ($NaClO_3$) as a weed-killer. Another chemical combination is potassium chloride ($5KCl$), and this is easily matched by sodium chloride ($NaCl$), which is common or table salt. This has long been known as a weed-killer, and was used before weed-killers made with sulphuric acid were employed. Possibly you were thinking of sodium chloride being used in England and France for killing weeds on paths, for it has been used for more than fifty years to our knowledge, although less often now than formerly. The plan is to scatter it over drives or paths until they look white, choosing dry weather for the operation, and leaving the salt to do its work. The salt disappears in the course of a week.

Remarks.—Business suffered greatly through severe weather. All vegetables arrived in a frozen condition, in some cases despite special packing to counteract the conditions.

GLASGOW.

There was a marked decline in the volume of business transacted in the cut flower market last week in consequence of the severe climatic conditions and the poor condition of blooms from the south of England which, after their very long railway journey, arrived in a more or less frozen state. Locally grown material, having the advantage of quick transit, did not depreciate to any extent, and therefore obtained steady prices, but the general trend of values of Tulips and Daffodils was towards lower levels. Of the former, Bartigon was worth from 1s. 2d. to 1s. 6d. for 6's; Le Notre, 1s to 1s. 4d.; William Pitt, 10d. to 1s. 4d. Couronne d'Or, Tea Rose, Flamingo and Prosperity, 9d. to 1s. 2d.; William Copland, 8d. to 1s. 2d.; Brilliant and White Hawk, 8d. to 1s.; Murillo, Prince of Austria and Thomas Moore, 6d. to 1s. Daffodils were offered in greater variety, King Alfred realising 2s. per dozen; Victoria, and Sir Watkin, 1s. 8d.; and Golden Spur, 10d. to 1s. 2d.; Narcissi sold at 2s. to 3s. per dozen bunches. Carnation prices anged from 3s. to 6s. per doz. Arum and Lilium Harrisii, 10s. to 12s.; Lily-of-the-Valley, 1s. 9d. to 2s. 6d. p bunch; Lilac, 2s. to 3s.; Prunus, 2s.; Mimosa, 11s. per pad; English Violets, 2s. to 3s.; and Smilax, 1s. 6d.

The fruit market was particularly quiet, Apples being a little cheaper. Winter Nelis Pears realised from 13s. 6d. to 17s. per case for Washington brands, and 17s. per half-case for Californian. Valencia Oranges, 200's and 240's, sold at 17s. to 24s.; 300's, 17s. 6d. to 28s.; 360's and 504's, 15s. to 20s.; large, 714's, 24s. to 30s.; and large, 420's, 28s. to 33s. Palermo Lemons made 15s. to 17s. per case; and Murcia Lemons, 14s. 6d. to 16s. 6d. half-cases. Grape Fruits sold at 15s. to 22s., according to counts; home-grown Grapes at 3s. 6d. to 4s. 6d. per lb.; Cape Nectarines and Peaches, 5s. to 8s. per box; and Plums, 5s. to 6s.

In the vegetable section, Cucumbers advanced in price to 30s. per dozen; Lettuces sold at 3s. to 4s.; Cauliflowers, 2s. 6d. to 3s. 6d.; Mushrooms, 2s. per lb.; and Rhubarb, 30s. to 35s. per cwt.

TRADE NOTES.

Originality is one of the keynotes of successful advertising, and we congratulate Mr. R. F. Calvert, the well-known Narcissus specialist, of Carnsulan Nurseries, Coverack, Cornwall, on the attractive series of calendars, tastefully decorated with coloured illustrations of some of his Narcissus novelties, which he has issued in conjunction with his instructive and comprehensive catalogue.

Patents and Trade Marks.—Any of our readers requiring information and advice respecting Patents, Trade Marks or Designs, should apply to Messrs. Rayner and Co., Patent Agents, of 5, Chancery Lane, London, who will give free advice to readers mentioning *The Gardeners' Chronicle.*

WEATHER IN JANUARY.

This was the calmest January, and one with the least westerly winds, in the fifty-eight years' history of the Southport Observatory. S.W. winds also were nearly absent. Barometric pressure was very high and remarkably steady. Except during the last few days, the weather was almost continuously cold, but with little precipitation. Much colder January months are, however, on record. The mean temperature was 35·9°, or 3·2° below the average. Rain fell on 14 days—the normal number; but the total was only ·40 inch, which was 1·28 inch less than the average. An aggregate of 39 hours of bright sunshine was recorded, or merely four hours short of the normal. Frost on the grass occurred almost nightly; on 19 dates there was frost in the shade. Snow was only seen three times, and the total depth (unmelted) did not exceed 1½ inch. Thick fog was also restricted to portions of three days. Slight hail fell on the 17th. There were no gales. *Joseph Baxendell, The Fernley Observatory, Southport.*

CATALOGUES RECEIVED.

Maxwell and Beale, Broadstone, Dorset.—Hardy Primulas.
Patrick's, Sevenoaks, Kent.—Roses, Fruit Trees, Shrubs, Climbing and Herbaceous Plants, etc.
C. Engelmann, Ltd., Saffron Walden.—Carnations.
Clibrans, Ltd., Altrincham.—Sale Catalogue—Trees, Shrubs, Pot Plants, etc.
Chase, Chertsey, Surrey.—Chase Continuous Cloche.
Waterer, Sons and Crisp, Ltd., Twyford.—Clearance Sale of Herbaceous and Alpine Plants.

Foreign.

Yokohama Nursery Co., Ltd., Japan.—Tree and Shrub Seeds, Japanese Flower and Vegetable Seeds, Shrubs, Herbaceous Plants and Sundries of Japanese origin.
Henderson and Co., New York.—Flower and Vegetable Seeds, Roses and Hardy Perennials.
Treppens and Co., Berlin.—Flower and Vegetable Seeds Pot Plants and Garden Sundries.
Hill Floral Products Co., Indiana.—Roses, Carnations and Chrysanthemums.
Paul Zacharias, Ermsleben.—Wholesale Seed List.
Chas. F. Barber, Oregon.—Hoodacre's Delphiniums.

GARDENING APPOINTMENTS.

Mr. Robert Scrimgeour, for the past fifteen months Gardener to Col. P. Lester Reid, Thorpe-Mandeville Manor, Banbury, Oxon., and formerly for two years Foreman to Lord Hamilton of Dalzell, Dalzell House, Motherwell, as Gardener to General Stirling, Keir House, Dunblane. Mr. Scrimgeour commences his new duties on February 25. (Thanks for 2/6 for R.G.O.F. Box.—Eds.).

Mr. Ed. O. V. Griffiths, for the past two-and-a-quarter years Foreman in the glass department at Berwick House Gardens, Shrewsbury, Salop, as Gardener to Mrs. C. Gurney, Yew Tree House, Royston, Hertfordshire.

Mr. H. Thomas, for the past three-and-a-half years General Foreman to H. C. W. Foster, Esq., Hornby Castle, Hornby, Lancaster, as Gardener to F. A. Haworth, Esq., Birtles Hall, Chelford, Cheshire. (Thanks for 2/- for R.G.O.F. Box.—Eds.).

SOHEDULE REOEIVED.

The Rhododendron Association.—Exhibition to be held at the New Hall of the Royal Horticultural Society, Westminster, S.W.1, on Tuesday and Wednesday, April 30 and May 1, 1929. Acting Secretary, Mr. Gurney Wilson, R.H.S. Hall, Vincent Square, S.W.1.

Royal Horticultural Society.

The Report of the Council for 1928, presented to the one-hundred-and-fifth annual meeting of Fellows, on Tuesday last, provides a large amount of interesting reading. At the outset, the Council refers with profound regret to the loss sustained by the death of its President, Lord Lambourne, and to the passing of Sir William Thiselton-Dyer, Mr. Frank Reader, and others to whom the Fellows owe a debt of gratitude. The new Charter and By-laws were granted under Royal Warrant on June 9, last, and these give the Council somewhat wider powers than formerly. The numerical progress of the Society is remarkable, inasmuch as although there were no fewer than 1,557 losses by deaths and resignations, there was a net increase of 1,097 Fellows during the year; the total number of Fellows on November 13, last, was 26,356; this is a record of which any Society might well be proud. Moreover, six hundred kindred and local societies are affiliated to the R.H.S. The Report deals briefly with the various exhibitions, conferences and competitions held during the year, the deputations to Ghent and Harrogate, and the award of various medals. Then come references to the work in the Society's gardens at Wisley, and, although we have no desire to stress the point unduly, the Report certainly does not indicate a particularly handsome return for the £12,017 15s. 0d. which Wisley cost during the year. True, the various Trials conducted were of value to the Fellows and to seedsmen, and the gardens themselves are full of interest to those able to visit them. We are glad, however, to learn that—as already stated in these columns—the new disease of Meconopsis is being investigated, that research work in regard to the hot-water treatment of bulbs—so admirably begun by our late colleague, Mr. J. Ramsbottom—is being continued, and that experimental work is being carried out in connection with the effect of manures upon diseases of Roses and Gladioli, and the effect of light upon the growth and reproduction of plants. A report is promised concerning the effect of ultra-violet rays upon plant growth, but interest in the report is somewhat damped by the observation that "the general results show little in favour of the use of ultra-violet ray glasses for crop growing." The standard collection of hardy fruits is, we are told, being continuously added to, but what will probably please the general body of Fellows most is the establishment at Wisley of standard collections of such popular hardy flowers as Aubrietias, Asters, Cistuses, Crocuses, Delphiniums, Helianthemums, bearded Irises, Phloxes, Paeonies, Roses, Veronicas and Violas, and less hardy subjects such as Gladioli, Dahlias, Nerines, Freesias, Fuchsias and Lachenalias. If the collections are kept up to date and well cultivated, they should prove invaluable alike to trade and private growers. Passing on from Wisley, the Report draws attention to the principal additions made to the Lindley Library by purchase; by gift and purchase, 360 books and pamphlets have been added to this fine library during the past year. The Report concludes with thanks to the press, committees, judges and donors of seeds and plants, and draws attention to the International Horticultural Congress which is to take place in London in 1930. The finances of the Society are set out in no fewer than eighteen pages of the *Report and Book of Arrangements*. Those well versed in the art of accountancy will no doubt revel in the multiplicity of figures presented, but the ordinary Fellow finds such figures somewhat overwhelming, and looks in vain for an uninvolved statement that shows the financial position plainly and briefly. So far as we understand the position, the annual subscriptions come to £41,000 16s. 10d., and dividends and interest amounted to £2,900 1s. 9d., other items bringing the income to £53,774 13s. 3d. This left a profit of £22,686 12s. 3d., but of this sum £12,017 15s. 9d. was needed to balance the expenditure at Wisley, and £9,000 was placed to general reserve, leaving a balance of £848 13s. 6d. Certain investments have been realised—incurring a loss, on sale, of £2,087 5s. 4d.—and "partly used in the building of the New Hall," nevertheless, the balance sheet shows a General Reserve Fund asset of over £5,000 and an investment in Conversion Loan valued at £9,618 6s. 4d. It would appear, therefore, that the Fellows need have little fear for the financial position of the Society, notwithstanding its large commitments, and the prospective expenditure on increased Office and Library accommodation—an increase long overdue—and upon some other reconstructional work in the old hall.

Our Coloured Plate.—The original Odontioda Lambeauiana was raised by M. Peeters, nearly twenty years ago, by crossing Cochlioda Noezliana with Odontoglossum Lambeauianum. It arrested attention at once by reason of its brilliant colouring, the size and form of the flowers, and the graceful arrangement of the flowers on the spike. A similar cross has been made on several occasions since 1909, with the result that several varieties of Odontioda Lambeauiana have been raised and exhibited, notably O. L. Nellie, by Messrs. Black and Flory (Award of Merit, 1918); and O. L. Westonbirt variety, which was exhibited so well by Messrs. H. G. Alexander, Ltd., at the Chelsea Show in 1928, and is the subject of the Coloured Supplement Plate presented with this issue.

British Carnation Society's Secretaryship.—At a meeting of the Council, held on February 12, Mr. P. F. Bunyard, who has held the office of Honorary Secretary of this Society for a number of years, resigned, and Mr. F. W. Alesworth was elected to fill the vacancy. All correspondence relating to the Society should now be addressed to Mr. F. W. Alesworth, 17, Avenue Road, Isleworth, Middlesex.

Marking of Imported Tomatos.—The Public Enquiry into the application for an Order in Council under the Merchandise Marks Act, 1926, to require the marking of imported Tomatos in their fresh or raw state, will be held in Room 104, at 10, Whitehall Place, London, S.W.1, at 10.30 a.m., on Friday, March 22, 1929. Applications to be heard in evidence and any other communications with regard to the matter should be addressed, as early as possible, to the Secretary of the Standing Committee, Mr. H. J. Johns, 10, Whitehall Place, London; S.W.1.

The Sewell Medal for Alpine Plants..—Among the many enthusiastic cultivators of alpine plants in this country, none is more keen than Mr. A. J. Sewell, who has, in his beautiful garden at Ronneby, Oatlands Chase, Weybridge, a grand collection of alpine plants, embracing many rare subjects and the large majority of recently introduced novelties. In his unselfish desire to encourage the love of alpine plants among British gardeners, Mr. Sewell has provided the means whereby the Royal Horticultural Society is able to offer medals, struck in silver and silver-gilt, bearing Mr. Sewell's name, for exhibits of plants suitable for the rock garden or alpine house. In 1929, six medals are offered for award, two on March 26, two on May 7, and two on November 5. On each date one medal is offered for an amateur's exhibit, and one for a horticultural trader's exhibit of six pots or pans not exceeding twelve inches in diameter. The scale of points for judging these exhibits will be :—Suitability, 18 points; cultivation, 18 points; and rarity, 18 points. The competitions for these medals should prove extremely interesting, and, with alpine plants enjoying such widespread popularity as they are to-day, there should be no lack of exhibitors.

Manuring of Potatos.—The authorities of the Edinburgh and East of Scotland College of Agriculture have issued the results of experiments conducted at the Forfarshire farms of Oldbar, Lochty and Newton of Boysack, in connection with the manuring and varieties of Potatos. The average results at these three centres were as follows :—King Edward, 13 tons 6 cwts.; Arran Consul, 12 tons 9¾ cwts.; Great Scot, 12 tons 3 qrs.; Majestic, 9 tons 6 cwts. 2 qrs.; Ally, 8 tons 18 cwts. 1 qr.; and Golden Wonder, 8 tons 18 cwts. At Hillhead, Lawton and the Royal Asylum, Montrose, experiments were made with a view to ascertaining the limits of economic manuring. The mixture of manures are made up of 2 cwts. sulphate of ammonia, 2 cwts. superphosphate, 1 cwt. steamed bone-flour, and 2 cwts. sulphate of potash, distributed at the rate of 6, 8, 10 and 12 cwts. per acre. The average results at the three centres were :—Plot 1, 12 tons 9 cwts.; Plot 2, 13 tons 5¾ cwts. Plot 3, 13 tons 13 cwts.; Plot 4, 13 tons 19¼ cwts. The test here was to ascertain what crop increase could be obtained by successive applications of 2 cwts. of manure of value approximately 17s. The increase in Plot 2 over Plot 1 with Potatos valued at £3 per ton, shows a return of almost three times the extra outlay on manure. In Plot 3, the extra outlay is more than paid for, while in Plot 4, the value is still on the right side. This would seem to indicate that much larger dressings of suitable "artificials" might safely be given to Potato crops. It is proposed that further experiments on these lines should be conducted, starting with a heavier dressing and a more concentrated manure. Partly on the same lines an experiment was conducted at two centres with a view to ascertaining the effect of increasing the potash applied, and the results seem to show that an increased dressing of potash does not give satisfactory results unless the quantity of nitrogen is also increased. They show that no satisfactory increase has been secured by using more than 2 cwts. of sulphate of potash per acre, but in another experiment a satisfactory increase was obtained where the dressing of potash was equivalent to 3½ cwts. per acre.

Scottish Seed Potato Sales.—A number of auction sales took place last week in Scotland which indicate the market value of varieties of seed Potatos. At Hamilton the entries numbered 136 as against 96 last year, while the tonnage on offer also showed a considerable increase. Certain varieties, such as Arran Consul, were not in demand at any price, but of other sorts sales took place at the following quotations:—Sutton's Abundance, up to 95s.; Kerr's Pink, to 90s.; Arran Banner, to £12; Arran Chief and Arran Victory, to 65s.; Golden Wonder, to 85s.; Great Scot, to 90s.; Herald, to 80s.; and King Edward, to 107s. 6d. At Kilmarnock, the highest prices realised were:—Kerr's Pink, 80s.; and Golden Wonder, 100s.; while at a special sale Golden Wonder realised 160s., and Kerr's Pink, 75s. per ton.

Glasgow Flower Show.—The annual exhibition promoted by the Corporation of Glasgow and the Glasgow and West of Scotland Horticultural Society, is to be held in the Kelvin Hall on September 3, 4 and 5, a week later than in 1928. Owing to the liberality of the Corporation in increasing the prize money from £1,000 to £1,200, a more attractive schedule has been prepared by the addition of a honey and bee section.

Culinary Pea Competition at Westminster.—The Royal Horticultural Society is arranging a culinary Pea competition, to be held at Vincent Square, Westminster, S.W.1, on July 16. There will be no entrance fees. The classes are as follow:—(a) 6 distinct varieties of Peas, 1 dish of each; first prize £3; second, £2; third, £1.: (b) 3 distinct varieties of Peas, 1 dish of each; first prize, £1 10s.; second, 15s.; third, 10s. Any amateur may enter in either class, but not in both. Schedules and entry forms are obtainable from the Secretary, R.H.S., Vincent Square, London, S.W.1.

Brussels Linnean Society Banquet.—For many years past, it has been a tradition of the members of the Brussels Linnean Society to meet for an annual fraternal gathering, which takes the form of a banquet at which the various prizes won at the horticultural exhibitions are distributed. This distribution takes place on the third Sunday in February, and prize-winners, judges, and all the élite of the horticultural community makes its way to Brussels for the occasion. Unfortunately, this year, February was distinguished for its extreme cold, and influenza has taken a heavy toll of horticulturists in Belgium, so that there were many gaps in the ranks, and many telegrams and letters from members who were obliged to keep their beds. The banquet is also made the occasion for congratulating those who have been decorated during the past year, and this year there was quite a galaxy of members whose names had been inscribed on the roll of honour, including M. Fr. Spae, Commander of the Order of Leopold II; MM. Ch. Pynaert and V. Van der Kam, Officers of the Order of the Crown; MM. Alb. De Smet and Emile Praet, Chevaliers of the Order of Leopold II; and others too numerous to mention. Altogether, about sixty guests assembled around the tables in the large salon of the Taverne Royal, M. Firmin Lambeau, in excellent health, presiding with his accustomed geniality. The President proposed the first toast, to the recipients of decorations and the members of the press, M. Pynaert replying for the first-named guests, and M. Van Wyngaerden for the press. Other toasts followed, an orchestra enlivened the proceedings, dancing followed the banquet, and altogether a very gay and festive evening was spent by all present.

Mr. Gerald W. E. Loder.—Unanimously and enthusiastically elected President of the Royal Horticultural Society, on Tuesday last, Mr. Gerald W. E. Loder will have the full support of all horticulturists, because he is an able gardener, has a delightful personality, and is a capable administrator. In his garden at Ardingley he has fine collections of plants, and in these he takes a keen and knowledgeable interest and delight. His work on the Council has earned him such high respect and great regard that, after the death of Lord Lambourne, his colleagues honoured him by appointing him President in accordance with the terms of the New Charter, an appointment the Fellows present at the Annual Meeting endorsed in no uncertain fashion. Professional gardeners throughout the country will not forget Mr. Loder's interest in the Royal Gardeners' Orphan Fund, an interest he translated into hard work and a generous donation on the occasion of the Festival Dinner of this Charity in 1928. His capabilities as a speaker and chairman were demonstrated at that function, and he added to this reputation on February 26 by his chairmanship and his admirable address in moving the adoption of the Council's report. We add our congratulations to the many Mr. Loder has already received, and wish him a happy and successful term of office as President of a Society that only once before in its long history has been presided over by a great gardener—Thomas Andrew Knight—who was neither knight nor lord, nor needed a title to make him horticulturally famous.

MR. GERALD W. E. LODER.
President of the Royal Horticultural Society.

Beautiful Woodwork at Imperial Chemical House.—The home of Imperial Chemical Industries, Ltd., at Millbank, not far from the Houses of Parliament, is not only a wonderful building, it is a beautiful one. Although built with almost incredible speed, it is not "standardised," consequently no two of the several hundred rooms are exactly alike; indeed, there are scarcely two doors or two windows alike; in short, the British craftsmen have had their opportunity, and have taken full advantage thereof. The woodwork in the doors and panellings is a delight, and it is a pleasure to learn that the woods used came from different parts of the British Empire. For instance, the exquisite panelling in Lord Reading's room consists of Indian Laurel, dark and finely figured. Lord Melchett's room is panelled with English Walnut, several conference rooms are panelled with English Oak, while in one the handsome Australian Silky Oak (Stenocarpus salignus) is used with great skill and effect. Australian Black Bean, as used in a room on the first floor, is heavily figured, and lends itself to carving and moulding, as well as panelling. English Chestnut and Sycamore, Canadian Yellow Pine and Maple, Rangoon Teak and Mahogany from British Honduras, have been utilised in many parts of the building, either for doors, panelling or parquet flooring and skirtings, while the exquisite carvings in the Grinling Gibbons' style found in rooms on the sixth floor are in English Lime. There are no fireplaces or other ocular evidences of heating throughout the huge building, and yet, no matter what the outside condition may be, every room and corridor is pleasantly warmed. Everything possible has been done to secure the comfort of the directors and employees during working hours; leisure hours may be spent in the gymnasium, Badminton and Squash Racquets courts, etc., in the basement; while meals may be taken in the big Refectory or at the quick-lunch bar.

Permanent Allotments at Glasgow.—It has been recommended that the General Finance Committee should take into consideration the question of the expediency of Glasgow Corporation acquiring ground for permanent allotments, and that the Committee enter into negotiations with the owners of ground at present leased to the Corporation, extending to about twenty acres, with a view to its purchase for permanent allotments, if the land can be secured on reasonable terms.

Honours for Dr. R. A. Fisher and Dr. A. D. Imms.—These two members of the staff of the Rothamsted Experimental Station have been elected Fellows of the Royal Society. This is one of the highest scientific distinctions in the British Empire, only fifteen Fellows being elected each year and the choice ranging over the whole Empire. In addition, Dr. Fisher has been awarded the Weldon Prize of the University of Oxford for high distinction in Biological Science. With the election of Dr. Fisher and Dr. Imms to the Royal Society, Rothamsted now has three Fellows on its staff, Sir John Russell having been elected twelve years ago.

Pleasure Ground for Egham.—An anonymous donor has presented to the town of Egham, Surrey, an area comprising sixteen acres of land at Ankerwyke Corner, Egham, together with a refreshment chalet and attendant's cottage and tea garden, a large number of seats along the river bank at Egham, £200 towards the building of a bathing pavilion, and seven acres of land near Glanty Corner, Egham, primarily for the use of children. This generous gift has been accepted by the local Urban Council.

Cold Storage of Onions.—Experiments carried out at the Municipal Cold-Storage Works, Sydney, in connection with the treatment of Onions by refrigeration, have demonstrated that Onions can be kept in good condition in Australia from March until the end of December. This should greatly facilitate the distribution of the Australian Onion crop. Onions were placed in store, at various temperatures ranging from below freezing point to 38°F. The Onions were treated in two classes, (1) freshly-dug, and (2) well-matured Onions which had been dried in the fields for some days previous to being placed in the store. The varieties treated were Brown Spanish and Silver Skin. After three months, specimens were taken out of the cold stores and examined; they were found to be in excellent condition and of good appearance, especially those stored in a temperature below freezing point which, in the case of Onions, is 29°F. Brown Spanish withstood the thawing process well, but with the Silver Skin Onions it was found that unless they were thawed gradually they deteriorated in value. At the end of six months the remaining Onions were removed from the cold-storage and defrosted very gradually, when they were found to be in excellent condition; they compared very favourably with fresh Onions. It is interesting to note that these results, in the main points, are similar to those obtained from experiments conducted in America in the cold storing of Onions.

The World Supply of Lemons.—According to a recent issue of *Citrus Leaves*, Italy is the leading country so far as the exportation of Lemons is concerned, 7,000,000 boxes being dispatched to foreign markets each year. The annual Lemon crop of California is given as between 6,000,000 and 7,000,000 boxes, which is insufficient for home consumption, Lemons having to be imported into the United States in large quantities. Spain's annual production of Lemons amounts to approximately 300,000 boxes, but the greater percentage is consumed locally, while it is also stated that Palestine, Australia, South Africa, Sicily and some of the other smaller countries in which Lemons are cultivated commercially, barely produce enough for their own requirements.

Tree-planting of American Roadsides.—The *National Nurseryman*, of Hatborough, Pennsylvania, gives some interesting particulars of the work which is being done by the Massachusetts Department of Public Works to beautify the roadsides by judicious planting of native trees, shrubs and perennial flowers. The department is empowered by law to make roadside improvements, the work including such planting, replacements, and care as may be necessary. When a road is laid out as a State highway, it is generally made sufficiently wide to provide an area on each side for roadside improvement. No tree, shrub, or plant within such a highway can be cut, removed, or new ones added without a permit from the Department. The State has a nursery at Palmer, where trees and shrubs are propagated, and where the highway landscape supervisor trains men in the care of trees and in roadside beautification.

Gwydir Castle.—Admirers of the ancient and beautiful mansion known as Gwydir Castle, one of the most historic Tudor mansions in the country, will be relieved to hear that it has been purchased by Dr. G. H. B. Kenrick, K.C., to save it from the possible fate of being taken to America, or at any rate, becoming the property of an American owner. The first owner of the Castle, which is situated at Llanrwst, was Howell Cottmor, who fought under the Black Prince at Poictiers, and it was rebuilt in 1480. It came into the possession of the Wynn family in 1678, and remained in that family until eight years ago. The Dutch garden, with its rows of clipped Yews, is famous throughout the country; one Yew is stated to be over 1,000 years old. A fine specimen of Wistaria sinensis, covers the courtyard wall, and in the garden are two Oaks planted by the present King and Queen, who visited Gwydir in 1898. A suggestion has been made that the local authorities should organise a scheme to take over the Castle and gardens, and make them a place of public resort. It appears that it is not Dr. Kenrick's intention to live there himself.

Aid for Frost Victims in Belgium.—On the initiative of the Comte de Kerchove de Denterghem, Governor of East Flanders, Belgium, a collection is being made among horticulturists in aid of the small cultivators and nurserymen in the province of East Flanders whose produce has been destroyed by the extreme cold of the past few weeks. A special committee is being formed to organise the collection, under the presidency of M. Lucien de Cock, the well-known secretary of the Ghent Floralies.

Texan Horticultural Development—Horticultural research is making great strides in the United States, and we are not surprised to learn that under the direction of Mr. Hamilton P. Traub, the energetic Chief of the Division of Horticulture, Texas, there are to be eight experiment stations in various climatic sections of the State. The nurserymen of Texas are to co-operate with the Division in the experiments to be carried out, and will supply a good deal of the plant material necessary. It is believed that within a period of three years Texas will be well organised from a horticultural point of view.

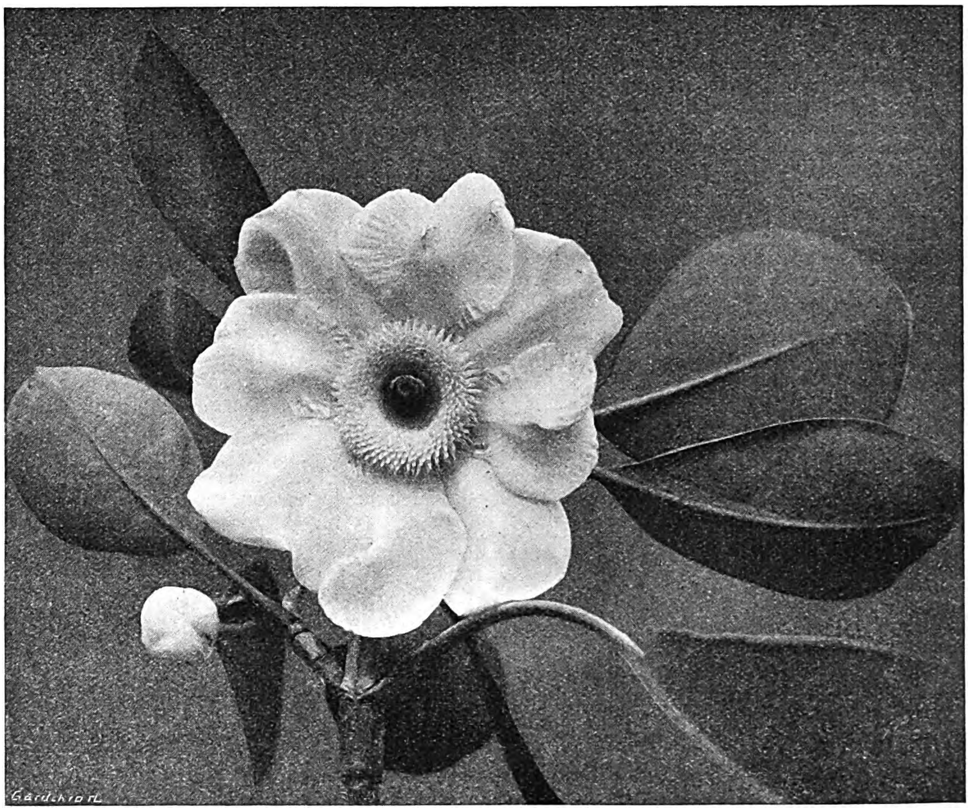

FIG. 77.—CLUSIA GRANDIFLORA.
(see p. 158).

Apple Marketing in Canada.—Commercial growers of Apples in British Columbia, owing to the magnitude of their crops, are adopting new intensive methods for the disposal of their fruits. Service stations for the distribution of them are being set up in important markets, and cartons of six or twelve Apples are stocked at these for sale to small purchasers. Apples are also being peddled in slot machines at five cents. each. It is also announced that British Columbian Apple growers may also seek to develop the at present neglected markets in Denmark, Sweden, Norway and other European countries.

Legacy to a Gardener.—The late Mrs. Emma Batty, of Cromwell Road, Hove, who died on November 23, 1928, left £200 to Mr. H. Ward, for many years gardener to her sister, Mrs. Campbell, of Charing.

Priority Right for Name of New Rose.—In the autumn of 1928, a French raiser exhibited a new Rose at a meeting of the National Horticultural Society of France; with the authority of M. Briand, the variety was named Aristide Briand, and this name was registered in November last, under the rules of the Fédération Horticole Professionelle Internationale, and published in the horticultural press. In December, 1928, an American raiser informed the President of the Rose section of the French Society, that he had the permission of M. Briand to give the name Aristide Briand to a new Rose. A special committee of the National Horticultural Society of France at once examined all the papers and dates concerned, proved that right of priority for the name belonged to the French raiser, and subsequently notified the American raiser that "Aristide Briand" could not be used by him, but suggested the use of President Briand, or Ministre Briand, as alternative titles to the one he had, unfortunately, chosen.

Appointments for the Ensuing Week.—MONDAY, MARCH 4: East Anglian Institute of Agriculture lecture. WEDNESDAY, MARCH 6: National Carnation and Picotee Society's meeting; Wimbledon and District Gardeners' Mutual Improvement Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. THURSDAY, MARCH 7: Royal Caledonian Horticultural Society's meeting; Western Commercial Horticultural Spring Show (two days); Bideford and District Horticultural Society's meeting; Sundridge and Brasted Horticultural Society's meeting. FRIDAY, MARCH 8: Royal Horticultural and Arboricultural Society's meeting. SATURDAY, MARCH 9: Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Cypripedium villosum.*—This fine addition to an interesting genus was lately exhibited to the Horticultural Society, when it received a Silver Knightian Medal. Mr. T. Lobb found it wild in the province of Moulmein at an elevation of 5,000 feet above the sea, and sent it to Messrs. Veitch, who, we believe, are its sole possessors. It most resembles C. insigne, differing more especially in the following particulars.—The scape is shorter than the leaves, and shaggy, with long, purple hairs; the petals are singularly unequal-sided, the posterior half being twice as broad as the anterior, and much undulated; they are, moreover, notched at the point, as if a piece had been struck out by a circular punch; the lower sepal is apiculate, and not merely obtuse. There is a general resemblance in colour, but the upper sepal instead of being decorated with dark, circular spots, has merely a deeply discoloured set of veins along the middle, and the petals, which look as if varnished, are a rich, warm brown on the upper or posterior half, but green on the lower half, with a deep rich brown line of separation. *Gard. Chron., March 4, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven-Moore, Manchester.

Sobralias. — These tall-growing, Reed-like Orchids, which produce their richly-coloured flowers in succession at the tops of the new growths, are vigorous rooting plants and require copious supplies of water at the roots each time the soil becomes fairly dry; those specimens that have not been repotted for a season or two, and are becoming root-bound, will be benefited by an occasional application of soot-water. As the young growths advance some of the older stems that have flowered may be removed by cutting them out close to their base, to allow more air and light to reach the new stems, to assist their development. These plants thrive well in a light position, in an intermediate temperature. As the hours of sunlight increase, the undersides of the leaves should be syringed on favourable occasions, to prevent damage by red spider and other insect pests. As the new stems lengthen, they should be tied loosely to a neat stake to prevent them bending near the base. Small plants that require more root-room should be transferred to larger receptacles, in which ample drainage should be provided, using a compost of good fibrous loam, with a few dried Oak or Beech leaves, well broken up, and a small quantity of short fibre, with plenty of crushed crocks. The ball of roots should be in a fairly moist state when transferred. Very little water will be needed until the fresh roots are active, when a larger quantity will be required. Any division of larger specimens is best carried out later in the season, after the flowering period. Scale insects are often found in the axils of the leaves, and these should be removed with weak insecticide applied with a small brush.

Vanda coerulea.—This handsome and highly decorative Orchid always commands admiration when in flower during the late summer and autumn months. Plants that have been in a partial resting state during the winter are now showing signs of activity and will require in some instances, fresh rooting material. Water should be afforded sparingly until growth is more active. The pots and surroundings should be sprayed in favourable weather, and when the plants are well established they should be allowed plenty of sunlight and a free circulation of air night and day; they only require light shading from strong, direct sunshine.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Pot Vines.—If the flower clusters were reduced to the requisite number for the crop before they came into flower, and those retained have set well, no time should be lost in getting the fruits thinned, as every day lost detracts from the size of the berries, which are never too large on pot vines. After thinning the fruits, top-dress the plants with rich compost, bone-meal or vine manure, after which feeding with diluted liquid manure must be relied upon for sustaining the vines, as the soil in the pots will soon become exhausted. Syringe the walls of the house and surface of the bed, and keep the evaporating pans filled with diluted liquid manure; this will help the vines, provided it is not strong enough to injure the roots and foliage. Pinch back the laterals, and stop at the first leaf those which develop on shoots carrying bunches; those on the other growths may be allowed a little more freedom, as every full leaf exposed to the sun will help the development of the berries. Ventilation will require attention hourly, as anything approaching a check or chill may result in rusted or scalded berries. A little air may be given with a rising temperature of 75°, and gradually increased or reduced, as the case may be, until the temperature remains steady at 80°. Gradually reduce the air and finally close the house in time to secure a rise in temperature to 85°, when atmospheric moisture aided by gentle warmth in the pipes, will favour rapid development of the foliage and berries.

Late Vines.—These vines, having been pruned, top-dressed and cleansed, should now be started, closing the house at once. This is especially important where such varieties as Lady Downe's and Gros Colmar are grown. Both these varieties require a long season of growth to bring out their best qualities, and no other Grapes illustrate and confirm the opinion that improved flavour accompanies good colour, better than do these varieties, especially the latter. Berries deficient in colour are very inferior, and good colouring can only be obtained by starting the vines early. Mrs. Pearson, Mrs. Pince, and other late kinds are all improved by a long season of growth. The advantages of an early start are apparent in a season like that of 1927, when vines started of their own accord stood little chance of maturing a crop of Grapes. A little fire-heat may help in the autumn, but no amount of fire-heat will finish ripening the Grapes when once the leaves begin to decay. The best time to apply fire-heat is at the commencement of the season, when a little suffices. Should the summer prove hot and dry, no harm will follow, as artificial heat may then be almost dispensed with for the remainder of the season. All these Grapes require time as well as heat, hence the importance of an early start. Such varieties as Alicante, Gros Maroc and Alnwick Seedling are classed as late Grapes, but they do not require quite so long a season; Muscats, however, are best started in February.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Layering Rhododendrons, etc.—The operation of layering Rhododendrons and other shrubs may be carried out at any season, but spring is usually regarded as the best time. Layering is a simple method by which good plants of choice varieties may be obtained in a short time, yet it is seldom adopted in private gardens. With Rhododendrons, as with other plants, it is essential that the part layered is fixed firmly into the ground by pegging it down, using strong Hazel or other pegs, or bent wire. It is also important that the layers be placed at a sufficient depth to ensure a regular supply of moisture during the summer. Before layering them, the stems should be cut partly through or notched, to check the flow of sap and to cause roots to be emitted sooner. Unless the soil is of a peaty nature, it will be advisable to surround the part layered with a compost of peat and leaf-mould in the case of Rhododendrons, Azaleas, and other peat-loving shrubs. As a general rule, Rhododendrons are best left for two years before severing the layered portion from the parent plant; some may require longer if there has not been a constant supply of moisture. The majority of deciduous shrubs may be rooted from cuttings of either soft or hard wood, but there is sometimes the lack of accommodation to practice this method and, where only a few plants are required, layering will be found a ready means of securing them. These layers will, as a rule, be ready to sever from the parent plants at the end of the first season.

Aquilegias.—As with some other herbaceous plants, the best results with Aquilegias are obtained by raising them from seeds annually, especially in the southern parts of the country, where they are not so long-lived as in the north, and, after the first season of flowering, soon lose vigour and dwindle away. To secure good specimens for planting in their flowering quarters in the autumn, seeds should be sown now without delay, as Aquilegias require a long season of growth if the best results are to be obtained. If space is available in cold frames during winter, I have found sowing seeds in early autumn, pricking out the seedlings when large enough into boxes, and wintering them in frames, then transplanting to well prepared nursery beds during early April, a good method. The few extra months of growth thus secured afford the necessary time to build up strong, vigorous crowns which give excellent results. There are many well-known strains of the long-spurred section, which are the most useful for garden decoration. Some firms offer distinct colour varieties, but it is impossible to procure a strain which is sure to come true to colour. The nearest approach to trueness is secured in shades of blush and blue. Among Aquilegia species, the most popular is A. glandulosa, from Siberia. This delightful plant, of close, tufted habit, with large flowers of a beautiful dark blue, grows to about nine inches high, and is ideal for grouping on the rock garden. It likes a deep, moist, well-drained, sandy soil, and resents disturbance when established; it loses vigour after a few years, therefore periodical sowing should be practised to keep up a supply of healthy plants. A. coerulea is a slender plant, in height ten to fifteen inches, useful for planting on large rock gardens. It has not a robust constitution and should be raised annually from seeds. A variety of this known as A. c. Mrs. Nicholls has much to recommend it as a choice plant for the front of the herbaceous border. Growing about eighteen inches high, it is a vigorous grower and bears flowers of a pale Cambridge-blue. A. alpina, another useful sort for the rock garden, grows to about twelve inches in height and has flowers of a dark blue; it likes a moist, sheltered spot, in sandy loam. A. pyrenaica has flowers of a bright lilac-blue. For the herbaceous border, A. chrysantha, from California, is one of the best of the species; it grows to about four feet high, its flowers being deep yellow, tinted with cream and pink at the base. A. Skinneri, in its true form, is a rare plant, with greenish-yellow flowers, the long spurs of which are bright orange-red. This species, like many others, gives the best results if raised from seeds each year.

HARDY FRUIT GARDEN.

By Henry H. Cook, Lecturer in Horticulture, Reading University.

Strawberries.—In recent years the cultivation of the Strawberry in this country has given considerable anxiety to private and commercial growers alike. What was at one time considered a profitable subject to grow, particularly in Kent and Hampshire, Devonshire and Cornwall, is now a very risky commercial proposition. Where the plants do grow the yield of fruits is most unsatisfactory. But, in the main, the plants have absolutely refused to make headway. Various suggestions have been put forward to account for this decrease in cropping powers and failure of growth, such as that the soil has become Strawberry-sick; that varieties propagated vegetatively for many generations undergo a natural deterioration; or that it is due to the presence of a virus disease. The decline is very serious in private gardens, but the loss must be considerably greater to commercial growers. There is every reason to hope, however, that a new lease of life has been given to the Strawberry, for investigations conducted at Long Ashton, Bristol, by Messrs. Ball, Mann and Staniland, have definitely proved that the plants have two periods in which they produce roots, viz., July, August and early September, and again towards the end of March and in April. These observations show that no sooner is a runner planted in July, than the root system begins to develop. Strong laterals extend from the main roots, and others are produced adventitiously from just beneath the basal leaves. The crowns grow but very little during the autumn months. By March, more fine lateral roots (feeders) are produced, and by the end of April they are very numerous and are, of course, all important as organs of food supply. Bearing these points in mind, every encouragement should be afforded the plants during these two periods. In July, after the crop has been cleared, form a mulch by hoeing a couple of inches deep between the rows, and drawing the loose soil up about the base of the plants, immediately below the bottom leaves, for it is at this point that the plant emits a fresh ring of main rootlets. The earliest opportunity should now be taken, when the ground is in a workable condition, to stir the soil between the rows with the hoe or hand cultivator, and to apply a top-dressing of artificial manure. The following mixture should suit most soils:—four parts of fine bone-meal, or bone-flour; two parts of sulphate of potash, and one part of sulphate of ammonia. Apply one good handful per yard of row, and sprinkle it close up to the plants, avoiding the foliage. It should be lightly worked into the surface soil, but farmyard manure should not be applied yet, unless it is forked in, as it only tends to prevent the warmer atmospheric air from reaching the roots. New plantations formed last July or August should be gone over carefully, and any of the plants which have become loosened at the roots by frost should be made firm again. Ground which has been prepared by trenching, etc., for a new plantation, should first be cropped with something that will mature and be cleared by mid-July, such as early Peas or early Potatos. These will leave the soil in ideal condition for Strawberry planting.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hatfield, Hertfordshire.

Hydrangeas.—Young Hydrangea plants that were propagated last season and have been wintered in cold frames or in a very cool house, may now be started into growth. The temperature at this stage may be from 50° to 55°. Until growths and roots are active, a little care should be exercised with regards to watering, but when they are in full growth and in a healthy condition they require ample supplies of water, supplemented by frequent applications of liquid manure. Hydrangeas may now be secured in quite a number of colours, blue-coloured flowers being the most favoured, and several substances are used to cause the blooms of Hydrangeas to take on this colour. There are several proprietary articles recommended to attain this end, but much will depend on their constant and regular use. Older plants may still be allowed to remain in cool-quarters to provide a succession to the younger ones, but they must be examined occasionally as they should never be allowed to get too dry.

Malmaison Carnations. — Young plants obtained by layering last August, which have been wintered in a cool house in sixty-sized pots, may, now that the days are lengthening, be potted into larger receptacles. The compost should be of an open nature and, in such condition, may be made tolerably firm by ramming. Two-year-old plants that were potted on last autumn may now be watered more freely than of late; weak soot-water will prove very beneficial to growth and, a little later, concentrated Carnation manure may be afforded, although care is necessary not to use this too freely, otherwise the centres of the blooms will be coarse. Frequent fumigating to keep aphis in check is necessary to obtain the best results.

Pelargoniums.—Old Pelargonium plants that were cut hard back last autumn will now be starting into growth and, if they are developing too many young shoots, they should be disbudded. Rooted cuttings that were potted singly into small pots may now require to be transferred into larger receptacles, and when they are well established in the new compost their growths should be pinched back to ensure a bushy habit. Grow the plants in a cool house on a shelf near the roof-glass to favour the development of short, sturdy growths, and fumigate or spray them at short intervals to ward off attacks of green fly.

Statice Suworowii.—This Statice is useful for greenhouse decoration. Seeds may be sown now in an intermediate temperature and, so soon as the seedlings may be handled safely, prick them out in pans or shallow boxes, subsequently placing them singly in small pots, from which, when sufficiently rooted, they may be transferred to five-inch pots, in which they may be flowered. Care is always necessary when affording these plants water at the roots for, if once over-watered in their early stages, they will end in complete failure. Later, a successional batch may be sown to produce flowering plants at the end of the summer.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Potato Onions.—These, which are superior to Shallots, may now be planted. The sets should be planted twelve to fourteen inches apart, in rows eighteen inches apart. The bulbs may be planted with a trowel. When they have matured, they may be pulled and dried off in the same way as for Shallots. The bulbs are much larger than those of Shallots and are more after the type of Onions.

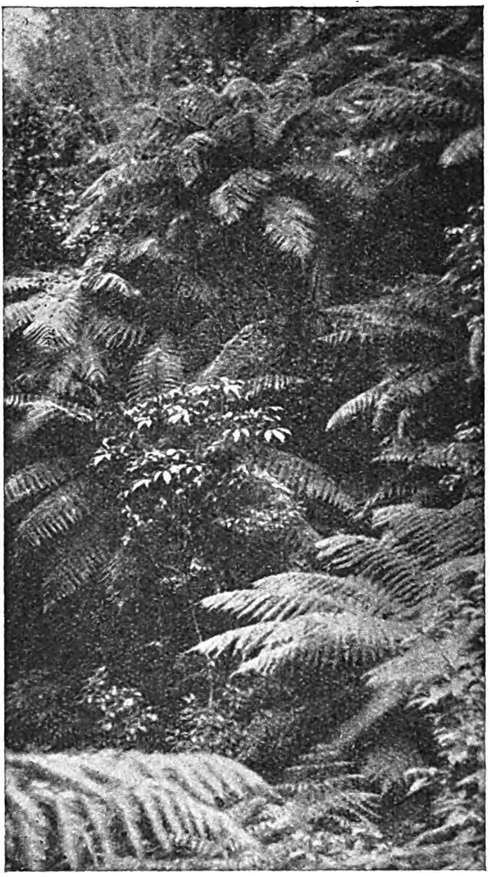

FIG. 78.—NEW ZEALAND FOREST.

Dicksonia squarrosa and Melicytus ramiflorus.

(see p. 161.)

Garlic.—Garlic should be planted now, preferably in a corner where it may remain. Garlic should be replanted every three or four years.

Seed-sowing.—Seeds of Celery, Celeriac, Parsley, Lettuce, Cauliflower and Brussels Sprout may be sown in boxes and germinated in heat. Snowball Turnip, and Beetroot, may be sown in frames to provide an early supply of roots.

Digging.—The ground from which Celery has been removed should be dug as deeply as possible, marking each end of the trench with a stake. This ground may be utilised for tall-growing Peas, the seeds being sown where the trenches were. Other vacant ground should be cleared of rubbish and then dug, dressing it, if necessary, with new lime. Another method of applying the lime is to place it in heaps on the ground after it has been dug, to allow it to slake itself, after which it may be distributed evenly and forked in, taking care not to leave the lime in thick patches; mix it well with the soil during the process of forking; if it is left in patches it may harm the roots of plants coming into contact with it.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

The Rock Garden.—Should favourable weather be experienced, March is a busy month in the rock garden. All decayed foliage, weeds and moss should be removed, and, if any replanting is to be done, the sites should be prepared, filling the pockets and beds with suitable compost. I find most alpines grow and thrive in a good, sandy loam, to which a fair quantity of sharp chips has been added. This may be used as the staple soil, leaf-mould, peat, or lime being added to suit the various plants. Established alpine plants should be top-dressed, using compost similar to that prescribed for planting, and the soil between them should be pricked over with a hand-fork. Planting should be done about the middle of the month. Autumn-rooted cuttings of alpines do splendidly if planted straight from the cutting frame; they may be planted more closely than pot plants, and consequently cover the allotted space in a shorter time. Endeavour to plant large patches of the various subjects if room permits, to secure as bright an effect as possible. Protecting material—panes of glass, etc.—that have been used for covering winter-moisture-hating subjects, should now be removed, as the lengthening days and more abundant sunshine render them unnecessary.

The Wild Garden.—Beds or specimen plants of Rhododendrons and Azaleas will benefit greatly if afforded a good top-dressing of peat or leaf-mould, although a good mulch of cow-manure, if procurable, is much better but, being rather unsightly, should be partly covered with soil. Cornuses and Willows, which are grown for winter effect, should be cut hard back now. Prune all shrubs which flower on the current year's wood, if this should be necessary. Many of these shrubs do fairly well without pruning, if room is allowed for their development, but a few, Hydrangea paniculata and Buddleia variabilis, for instance, do better if pruned rather hard. Remove all suckers from grafted Lilacs, Rhododendrons, etc. Planting of all deciduous trees and shrubs and all types of Roses should be finished at an early date.

Seed Sowing.—If a suitable opportunity occurs, a sowing of a good round-seeded variety of Pea may be made in a south border. Broad Beans may also be sown, Aquadulce being the best early variety, but if the ground is wet, defer the sowing for a week or two. If cloches or hand-lights may be placed over the seeds when sown, the resulting plants should be quite as early in producing crops as those raised in boxes under glass and planted out.

Sweet Peas.—Transfer autumn-sown plants, which are to be flowered under glass, to their final quarters, whether pots, boxes or a bed. They should be grown in light, sandy loam, not too rich, it being better to depend on surface feeding or applications of liquid manure after the first flowers develop than to give them a rich compost. Thoroughly water the plants before turning them out of the small pots, so that no further watering will be required until they have obtained a good root-hold in the new soil.

Pricking-off Seedlings.—As seedlings attain the rough leaf stage, prick them off at once and place them in a slightly warmer atmosphere for a few days; but hardy plants, Cauliflowers, Cabbages, Onions, Lettuces, etc., should not be kept for any length of time in a high temperature, or failure may result. So far as possible, place the seedlings so deeply that the cotyledons touch the soil, whether in pots or boxes.

General Work.—All growing plants under glass, with few exceptions, will relish a good sprinkling or syringing with clear water on bright days; this should be done early in the day, so that comparative dryness may obtain by evening.

PLANTS NEW OR NOTEWORTHY.

CLUSIA GRANDIFLORA.

According to Engler's classification of Guttiferae, Clusia is one of two genera forming the tribe Clusioideae. The genus comprises nearly a hundred species, inhabiting tropical America and the West Indies. They are mostly climbing epiphytes, usually destroying the trees on which they grow by strangling them. Of this comparatively large genus only a few species are cultivated in this country.

Under cultivation Clusia grandiflora is a strong-growing evergreen, requiring plenty of room in which to develop its horizontally extending branches. The leaves are thick and leathery in texture, dark green above and pale beneath, with a conspicuous mid-rib. Both surfaces are perfectly smooth, bearing a marked resemblance to those of Ficus elastica.

The flowering of this plant in cultivation is very uncommon, and few had the pleasure of witnessing it in this garden a few days ago, when a plant only two years old and barely two feet in height produced a flower. After some period of apparent idleness the large, fleshy, terminal bud revealed its treasure. This uncommon sight was of very short duration, for without any gradual transition from bud to fully open flower, it appeared in the night and just as quickly made its departure.

The flower (Fig. 77) was some six inches across, and any suggestion of grossness was completely dispelled by the ethereal delicateness of the colouring of the petals. The latter, usually eight in number, are white and wax-like. At the base of each is an irregular band of pink, of a purity and brightness all too rare in colours. In the centre of the flower is a group of staminoides, agglutinated together and overlayed by a soft layer of resin, appearing as a yellow, glossy disc; surrounding this are rows of ivory-white stamens, about five hundred in number, the inner rows being much shorter than the outer rows.

Clusia grandiflora is dioecious, and the Cambridge plant is the male form.

A large specimen flourishes here in the stove house, and its big leaves, often measuring eighteen inches in length, are a feature of great attraction the whole year through. Planted about forty years ago in a ten-inch pot, it soon reached the limits of its allotted space. The centre was cut back to nine feet from the ground, and the result of that operation was the production of six strong limbs in the upper two feet, leaving a clear stem of seven feet. The branches have from time to time been cut back, resulting in other lateral growths, which have often been treated in the same drastic manner.

This specimen flowered annually for a considerable period (see *The Gardeners' Chronicle*, December 2, 1905, Fig. 147), until a few years ago, when it received a severe check due to the failure of the heating apparatus. Three flowers were usually borne at the end of a shoot, the central one opening first and hiding the two side buds which opened later, each bloom being from seven to eight inches in diameter.

Growing in a mixture of loam and peat, and afforded liberal quantities of moisture in the atmosphere and at the roots, its cultivation presents no great difficulty. If the roots are allowed to ramble, they will, as is evident from the specimen here, soon leave the pot and search further afield for nutriment and moisture. The natural tendency to produce aerial roots is plainly visible in this lovely epiphyte, although it is growing under normal terrestrial conditions.

Clusia grandiflora may be propagated by cuttings, although this is often a very slow process and from six to eighteen months are required to produce a plant. This obstinacy in rooting seems to be due chiefly to the large amount of callus formation, and the removal of part of this obstruction prevents unnecessary delay. *Leonard G. Atkins, Botanic Gardens, Cambridge.*

ALPINE GARDEN.

PENTSTEMON HETEROPHYLLUS.

It is generally admitted that Pentstemon heterophyllus is one of the most beautiful of all the species of Pentstemon, and although it is recognised as a plant of not long duration, for it has the habit of dying off suddenly without giving any warning of its intentions, it is yet so easy to propagate that this delinquency should not deter the planting of it. It may be raised with ease from seeds, although plants so raised are liable to vary in colour, while cuttings of the young growths taken during the summer and inserted in a bed of sand in a cold frame root readily, and, if grown on and wintered in pots, make good flowering plants for the following season.

P. heterophyllus is an attractive subject for the rock garden, being best planted in groups of three or four in a warm position, not too fully exposed to the glare of the sun, and in moderately light, loamy soil. It forms a bushy plant and produces, from a semi-woody, short main stem, during the latter part of summer, slender stems to a height of one foot or so, bearing slender, tubular flowers of clear, rich blue, pale-throated and wide-mouthed, and marked and flushed with purple colouring. These inflorescences are produced freely, so that a group of P. heterophyllus in full bloom is a magnificent spectacle and one which cannot fail to command admiration. If one cannot accommodate it on the rock garden, it might well be afforded a position at the front of the herbaceous border, or in other favourable positions.

RANUNCULUS GRAMINEUS.

Although the mountain Buttercups include many beautiful sorts which are popular for the alpine garden, few of them are more desirable than the lovely R. gramineus, from the European Alps. It is not uncommon and is by no means difficult to obtain, while under cultivation it flourishes if planted in a cool, but not shaded nook, in deep, loamy soil.

R. gramineus forms a tuft of, as its specific name implies, grass-like leaves, narrow, and of a lovely glaucous, bluish-grey colouring. These alone are very attractive, but when in association with them during late spring and early summer, the glossy, rich lemon-yellow flowers are produced, the appearance of this Ranunculus is indeed charming. For these flowers are of good size and substance, clear in their colouring, slender-stalked, and borne gracefully on erect stems to a height of up to one foot.

This species is quite distinct among the many members of its family, and its culture should present no difficulties, for it is easy to establish and is, when happy, free in growth. I have also seen R. gramineus used very effectively as a pot plant in the alpine house, to which treatment it responds well.

This Buttercup is frequently referred to as R. graminifolius, but R. gramineus appears to be its correct name. *Kent.*

SEDUM LYDIUM.

According to the late Mr. Reginald Farrer, this small Stonecrop "affects mossy damp places and stream-beds at sub-alpine elevations in the mountains of Lydia and Caria" (see *English Rock Garden*), and although I, personally, have not attempted to grow it under such conditions, I can hardly picture it giving more satisfaction than it does when grown in the hottest and driest of situations, in poor, sandy soil, for when so treated, S. Lydium develops into a close mat, barely more than one inch high, and its growths, closely packed with tiny, cylindrical and fleshy leaves, lose all semblance of greenness, and take on deep and rich bronzy colouring, which they retain throughout the year. These growths are, during summer, terminated with small and compact heads of dark-anthered, pinkish flowers, but, to my mind, the charm of this Sedum appears in the rich colouring of its stems and leaves, even although they may be produced under what would appear to be unnatural conditions.

S. Lydium, like the majority of its relatives, is free-growing, its growths rooting as they spread, and, being of low stature and compact growth, it may be employed effectively for planting in the interstices of stone-flagged paths or steps on the rock garden.

TANAKAEA RADICANS.

Among the many attractive plants which Japan has given us is the dainty little, dwarf evergreen, Tanakaea radicans, which, in English gardens, asks no more than a cool, semi-shaded position and a free root-run in peaty or leafy loam. If such conditions are available in the alpine garden, and the average well-constructed rock garden has many cool and sheltered nooks, this subject may well be afforded a place, there to form a close and spreading tuft of slender-stalked, elliptic-pointed, leathery and regularly-toothed, rich green leaves; or, if not desired on the rock garden, T. radicans may be established in the open woodland, in a position not too far distant from a path, for it is of lowly stature and must therefore be viewed closely to be fully appreciated.

Tanakaea radicans is sometimes shy in the production of its flowers, but when this failing has been overcome and it is happily established, the tufts become crowned, in late spring and early summer, with dainty sprays of small blooms, in general appearance not unlike those of a dwarf Spiraea, and in colour a creamy-whiteness, borne on stems six or eight inches in height. It is only recently that this plant has been offered in this country, but now many nurserymen have stocks of it, and no difficulty need be experienced in obtaining it. *M. W.*

FLOWER GARDEN.

CONVOLVULUS ALTHAEOIDES AND C. TENUISSIMUS.

Convolvulus althaeoides is a common plant in many parts of the Riviera, where it shows a partiality for hot, sunny railway banks and dry walls. It has a rambling habit, thrusting its long, slender growths among the herbage or any low bushes that may come in its way. The flowers are of the open vase-shape common to the genus, nearly as large as those of the familiar Bindweed (C. sepium), and in colour a soft, amaranthine-pink, with a deep purple eye. The lower leaves are ovate, but the upper ones are deeply cut into narrow segments; they are all hairy.

C. althaeoides does not seem to be much of a success in our gardens, save in mild districts, and even in such it needs a warm, sunny place. Although it is frequently listed by nurserymen, the plant they usually send out under this name is, as Mr. E. A. Bowles has pointed out (*My Garden in Summer*), not C. althaeoides, but C. tenuissimus. This latter is easily distinguished by its greyer, almost silvery, leaves and stems, its more vigorous habit, and general hardiness. The only points of resemblance between the two species are the multifid foliage, the size and shape of the flower, and the twining, straggling manner of growth.

But in addition to the whiteness of the leaves and stems of C. tenuissimus, there is a difference in the colour of the blossoms, those of the latter being a brighter, almost rosy-pink. C. tenuissimus is an exceedingly attractive subject, but one that must be used with care, for it is a most enterprising traveller. I once had to take up a four-foot path and several square yards of rock work in my efforts to eradicate it, and even then it was only after years of pinching off every scrap that appeared that I finally saw the last of it.

Even so, this is such a charming plant, and its rosy blooms are so delightful in their setting of finely-cut, silvery foliage, that it is well worthy of being given some sunny corner of poor, stony ground, where it may weave its elegant tangle without jeopardising the lives of its neighbours. *A. T. J.*

TREES AND SHRUBS.

SALIX LANATA VAR. STUARTII.

Mr. J. Fraser (February 9, p. 107) rightly states it would be well to have the correct spelling of the name of this excellent little Willow. I saw it first in Mr. Clarence Elliott's nursery in the spring of 1926, and noted it as different from any form with which I was familiar. Strangely enough, two or three days afterwards Mr. H. E. Mason, of Alderley Edge, wrote offering me a plant and some cuttings for Wisley, which I gladly accepted, and it and they are now growing well. With them, Mr. Mason kindly gave its history. From this I gather that the plant was raised by the late Dr. Stuart, of Chirnside, N.B., after whom it was named. The correct spelling of the varietal name is, therefore, clearly "Stuartii."

The whole of the stock came into Mr. Mason's garden through Mr. John Wood, of Fitzroy Square, and Mr. Mason distributed cuttings to the Donard Nursery Co., to Mr. C. Elliott, and to certain private gardens.

The exact status of the plant is, perhaps, a little doubtful, and I hope Mr. Fraser may be able to clear it up. A herbarium specimen here from Mr. Mason's garden is endorsed by Mr. D. A. Haggart, who knows S. lanata well in its native Scotch haunts—"Salix lanata × lapponum or S. lanata × lapponum × repens . . . I think the cross S. lanata × S. lapponum the more probable." *Fred. J. Chittenden, Wisley.*

GENISTA AETNENSIS.

In a genus largely composed of dwarf or even prostrate shrubs, this species is of exceptional height, attaining, as it may, to twenty feet, with the appearance and trunk of a small tree. Nor is this height reached at the expense of decorative qualities, as happens with some of its allies, for the Rush-like, pendulous branches will clothe it almost to the ground level and so conceal any tendency to legginess. These slender growths are almost leafless, of a shining, greyish-green colour, and carry, in late summer, a shower of golden-yellow flowers, which are usually borne singly, but sometimes in pairs. The flowering period is often quite prolonged, scattered blossoms appearing until September.

Genista aetnensis is a native of Sicily, being found on the slopes of Mount Etna, as its name denotes. In cultivation it seems to require a warm, fairly sheltered spot, and rather dry or sandy soil, so that a wall is often a good position for the species. Nevertheless, it will grow to its largest size even when not so situated, provided there is good drainage and a little shelter from cold winds. Propagation may be effected by seeds or by cuttings inserted in a cold frame. It was introduced into cultivation in 1826, and is figured in the *Bot. Mag.*, t. 2,674, under the name Spartium Aetnense. *B. O. M.*

LONICERA HEDGES.

On page 107 (February 9), your correspondent *F.* refers to the numerous kinds of plants which he has seen used for hedges, including Lonicera nitida. I wonder, has your correspondent seen a hedge of Lonicera ligustrina var. yunnanensis (now called L. pileata var. yunnanensis at Kew). While, undoubtedly, L. nitida makes a beautiful hedge, I think the ideal plant for the purpose should possess more rigidity, and it is in this particular that L. p. var. yunnanensis excels, for it is of stouter growth. The leaves are a little larger and of a darker green (which is no improvement) than L. nitida, but the stouter habit of the variety renders it better for a hedge. When grown as a bush it also seems to retain its leaves on the uppermost parts of the plant in a way that L. nitida does not. It seems to me that, perhaps, the popular taste has adopted the wrong subject in planting L. nitida so extensively for hedges. As I have heard of a spurious form of L. p. var. yunnanensis which does not possess the characteristics of the true plant, it may be that herein, in part, lies the explanation of the comparative obscurity of L. p. var. yunnanensis. *J. Matchett Watson, Killiney Nurseries, Co. Dublin.*

GORDONIA ALATAMAHA.

There are numbers of plants, decidedly good ones from the decorative point of view, which are very little cultivated. In some cases the reasons for their comparative exclusion from gardens are well justified and can usually be traced to perhaps a particular failing in the plant's make-up. In other instances the cause is more difficult to find and may be of a nature unrelated to the plant itself.

The Gordonia (or Franklinia) with which this note deals, belongs to this class of lesser-known plants. A shrub of indisputable merits, it has one unfortunate weakness, best expressed by that unsatisfactory term, "lack of hardiness." But even then it is doubtful if this weakness is quite so serious as to warrant the general neglect that, in the past, this plant seems to have encountered.

A native of North America, it is the hardiest of approximately thirty other members of a genus scattered for the most part over tropical and sub-tropical Asia.

Gordonia Lasianthus, the Loblolly Bay, was the first of the genus to be named after Dr. James Gordon, of Aberdeen.[*] It is the only other American species, and is occasionally met with, but its inability to withstand the rigours of our winters debars it from a place in northern gardens. One other, an evergreen, Gordonia anomala, is sometimes seen in the greenhouse or even in sheltered places outside in Europe, and to a lesser extent in America.

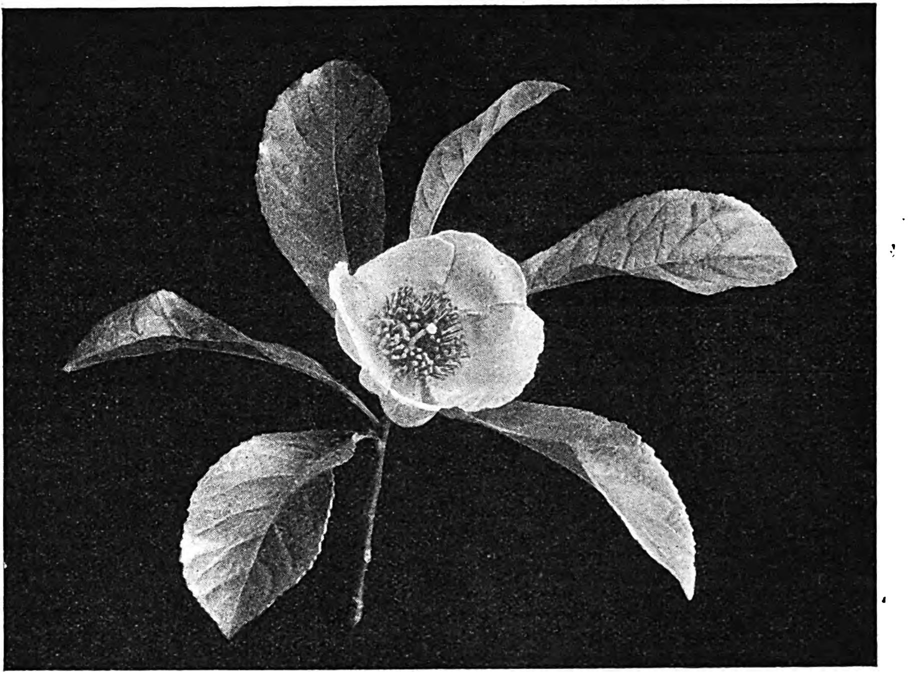

FIG. 79.—GORDONIA ALATAMAHA.

Gordonia alatamaha is a deciduous shrub, or tree, under good conditions attaining a height of thirty-five feet. A cultivated specimen once growing in the Bartram Botanic Garden, Philadelphia, was described as being so much as fifty feet tall.

In New England, as a result of frequent frost injury, it reaches a little over six or seven feet in height, and bears upright, basally-produced branches. In especially severe winters, however, it is liable to be killed back, possibly to within a few inches of the ground. In this event, the following season will see the production of plenty of young growths which, with favourable conditions, will bear flowers at the normal time.

The bark is smooth and the leaves, about twelve centimetres long, are obovate-oblong, serrate, hairy beneath and short-petioled. The short-stalked, silky, spherical buds open out into the purest white, Camellia-like flowers, golden-anthered, four-petalled, and about seven centimetres across. These are produced in continuous succession from the end of September until killed by frost. Should the plant be a fruiting specimen, and these are by no means common, the round, woody capsules will ripen the following year. It is this season of flowering, uncommon among hardy shrubs and at a time when the Gordonia is already exhibiting a bright display of crimson foliage, that makes this subject such a valuable asset to the garden.

Discovered in 1765 by John Bartram, at Fort Barrington, on the Altamaha River, Georgia, Gordonia alatamaha was first introduced into cultivation by William Bartram thirteen years later. From this original, and perhaps two subsequent introductions, all the existing specimens are descended. Since 1790, all efforts to re-locate this plant in its native habitat have gone unrewarded.

In this connection it is interesting to note that William Bartram[*] twice mentions that it was in the spring that he came across ". . . the new flowering shrub resembling the Gordonia, in perfect bloom as well as bearing ripe fruit," implying that the Gordonia flowered and ripened its fruits in spring and early summer. An early record for Philadelphia (1831) shows that it was then flowering in that vicinity in November, its normal season as we know it. This behaviour may be only natural, but it leads one to inquire to what extent such an apparently altered flowering period can be dependent upon changed climatic conditions.

Considering its "hardiness," or "ability to survive," in so cold a climate as Boston, it would seem highly probable that, although pronounced short-lived at Kew, there must surely be locations in the more favoured parts of Great Britain where this deserving shrub would be able to amply repay the little care necessarily expended upon it. Nevertheless, the Gordonia has still to be listed only among the decided rarities of the garden.

---

[*] In a covering letter Mr. Skinner points out that Altamaha and alatamaha are correct renderings (Franklinia Alatamaha and Gordonia pubescens were earlier names). His statement, however, that Gordonia was named after Dr. James Gordon, of Aberdeen, is not in accordance with Bailey (*Standard Cyclopedia of Horticulture*), or with W. J. Bean (*Trees and Shrubs Hardy in the British Isles*), while *Bot. Mag.*, t. 668, states, "The name of Gordonia was given in honour of the late Mr. James Gordon, a very celebrated cultivator of rare plants in Mile-End, by Mr. Ellis, who settled the genus from a specimen which flowered at Benjamin Bewick's, Esq., at Clapham, in the year 1768."—Eds.

[*] *Travels in North America*, by William Bartram, p. 467, (Philadelphia, 1791).

During the last century a number of plants were recorded as flowering in England, but these are now, with few exceptions, if any, apparently non-existent. It is to be hoped that the more recent efforts to cultivate this plant will meet with every success.

Emulating its natural choice, a sheltered, moist situation on a soil inclined to be peaty, would be nearest the ideal, although in the matter of soil the Gordonia is not fastidious. *H. T. Skinner, Arnold Arboretum.*

LATE-SUMMER AND AUTUMN-FLOWERING SHRUBS.

DURING July, August and September, hardy flowering shrubs are few compared with those of the preceding three months. As the early part of March is a very good time for planting such subjects, the following selections of flowering shrubs may prove of value to intending planters.

The named varieties of Ceanothus are among the most showy of the late-summer and autumn-flowering shrubs, producing, as they do, from July until October, a succession of flower spikes in numerous shades of mauve, blue and pink. They delight in warm, sunny positions and well-drained, light and porous, rather than heavy, soils. The best flower spikes result from fairly hard pruning, shortening the old flowered shoots of the previous year back to within four to twelve inches of the main stems during March. A selection of the best varieties includes Gloire de Versailles, deep powder-blue; Henri Defossé, rich, dark blue; Marie Simon, a dwarf, free-flowering, pink-flowered hybrid; Gloire de Plantieres, deep blue; Ceres, rose-pink; Indigo, rich, deep blue; Perle Rose, carmine-rose; Pinguet Guindon, lavender, tinted pink; Topaz, bright blue; and Arnoldii, a free-growing sort with branching panicles of pale, powder-blue blossoms.

In all but the coldest localities the varieties of Hibiscus syriacus, or Tree Mallows, as they are termed, are very valuable autumn-flowering shrubs. They grow to ten feet high or more in the mild climate of the south and west, and positions in full sun should always be chosen for them, as H. syriacus is a native of the Orient, where the climate is milder and more sunny than that of Britain. The partiality of the Hibiscus to sunshine was well demonstrated during the hot summer of 1921, when the bushes produced clusters of blossoms all along their branches. Such a useful flowering shrub is worth a south wall or fence in cold northern gardens.

There are varieties with single and double blossoms, the former, as a rule, being the most pleasing. The best of these are Coeleste, light blue; Hamabo, white, with chocolate blotches; Rubis, ruby-red; and totus albus, white. Double sorts include Lady Stanley, white, blotched maroon; Duc de Brabant, red; Jeanne d'Arc, white, with rosy markings, and amplissimus, vinous-rose.

Two hardy Hydrangeas, H. arborescens var. grandiflora, from the United States, and H. paniculata var. grandiflora, from Japan, are valuable autumn-flowering shrubs in gardens where the popular Hydrangea hortensis fails. If subjected to fairly hard pruning each year in February or March, cutting the growths back to within a foot or eighteen inches of the ground, the plants grow three to four feet high and produce an abundance of large heads of milk-white flowers. Both are effective shrubs for grouping in the pleasure grounds and at the front of shrubbery borders.

Two Brooms are of special value for late summer-flowering. Cytisus nigricans, although introduced two centuries ago from Central Europe to British gardens, is not commonly cultivated. This shrub requires fairly close pruning each year in spring, before new growth begins, as the flowers are produced on the current season's growths. The pruning will keep the bushes to a height of from four to five feet, and from July to September many slender racemes of yellow blossoms will be produced. Seeds provide a ready method of increasing this species. The second Broom is Spartium junceum, one of the best half-dozen flowering shrubs for town gardens, although it does best when planted in open, sunny positions. The plants thrive in poor soils and are splendid subjects for dry banks. Its one fault is a long, gaunt habit of growth when left to fend for itself. The remedy for this is to nip off the ends of the shoots several times during the summer when the plants are young and, subsequently, to shorten a proportion of the growths each year in March. This treatment practically ensures a wealth of blossoms from July to October annually.

The New Zealand Veronicas are delightful flowering shrubs in sheltered positions, but in cold districts they are invariably damaged by frosts and cold winds. As a rule, they appear happiest in maritime regions. The hardiest of all is Veronica Traversii, an attractive evergreen bush up to five or six feet high and as much in diameter, which, in July, becomes covered with white flowers. Others deserving attention are V. angustifolia, white, tinted with lilac; V. anomala, white, tinted pink; V. Hectori, with white, pink-tinted blossoms; and V. Autumn Beauty, a free-flowering, dark blue variety of spreading habit, which attains a height of twelve to eighteen inches.

Olearia Haastii is a close-growing, evergreen bush of rounded habit, from about five to eight feet tall, and covered in July and August with clusters of white, Daisy-like blossoms. An occasional specimen of this Daisy Bush, ten or twelve feet high, may be met with, but by this time the specimens are rather loose-limbed. Few shrubs respond more readily to drastic pruning. Cutting the growths back hard to the old wood during April induces new shoots to grow freely from wood two inches or more thick, and by the second season good bushes result.

Two species of Clerodendron, namely, C. trichotomum and T. Fargesii, from China and Japan, attain the dimensions of small trees when trained on single stems. They are, however, more attractive when grown as large shrubs on a lawn, or in a shrubbery border. Both bear white flowers during August. C. trichotomum has dark blue, almost black, fruits, those of C. Fargesii being porcelain-blue. A third species, C. foetidum, from China, is only shrubby in mild localities. At Kew the stems are killed to the ground each winter, but vigorous young shoots grow from the stools up to four feet or more high, and are terminated in autumn by large corymbs of attractive, purple-red flowers. *A. O.*

ROSE BREEDING.

IN his lecture to the International Rose Conference, Mr. Osborne, of Kew, stated that there is scope for the production of a hardier race of Roses than the Hybrid Teas, a race capable of withstanding the Canadian winters. I quite agree with Mr. Osborne, and as I have carried out some experimental work with this end in view, some of the results may be of interest to other Rose-breeders.

On the whole, I have found that hybrids of R. rugosa, with even such an extremely hardy H.T. as Grus an Teplitz, are not reliably hardy, a row of seedlings of this cross having been killed, root and branch, during the winter of 1926-27. Our native species, or hybrids of them with other species, seem, to me, to give most promise as a good foundation for a new and hardier race. In this part of Canada we have three native species, namely, R. acicularis, R. blanda and R. suffulta. Of these three, I find that the first-named does not mate readily with other species, but a hybrid between it and R. rugosa will set seeds to the pollen of a great many other species and types. Crossed with R. Beggeriana, it has produced a shrub having glossy, rugose foliage, and rather thin-petalled flowers that are produced continuously from June until frost comes. The handsome fruits are twice the diameter of those of R. Beggeriana and are produced freely. This hybrid, and a few between the dwarf Polyantha Roses and R. rugosa, and R. rugosa × R. acicularis, are the only hybrids of my raising which have so far inherited the habit of continuous flowering. Many other hybrids having this R. rugosa × R. acicularis cross as seed parent have been raised and are under test for hardiness, including some having as pollen parents such fine varieties as Rev. Page Roberts, Madame Butterfly, Etoile de Holland and Grus an Teplitz. One of the latter, although it has not yet flowered, is a very vigorous and promising looking bush.

Rosa suffulta, like R. acicularis, I have found hard to work with, but have managed to secure hybrids between it and R. blanda alba, R. rugosa and Harisson's Yellow; some of these may prove fertile and therefore a basis for further experiments.

Rosa blanda has, however, proved the most amenable species, and I have succeeded in crossing it with many other Rose families, including R. rugosa, R. multiflora, R. Beggeriana, R. spinosissima and the old, double Pink China Rose. One of my R. blanda hybrids, which I have named Betty Bland, has double, pink flowers throughout June, and its bright ruby-red canes give quite a touch of colour to our winter landscape. It has proved both hardy and fertile.

Of course, a great many of my hybrids have proved quite sterile, several of them being mere freaks; in one case, having neither petals nor stamens. Curiously enough, some of the worst offenders in this respect have had the Moss Rose as pollen parent. Seedlings having Frau Karl Druschki as pollen parent have also been quite worthless and sterile. Quite a few of my hybrids have not been quite hardy here, and as hybrids of our native species, with the exceptions already named, flower on the old wood only, it is sometimes difficult to flower those that are killed back in winter. One hybrid between R. blanda and Clothilde Soupert was seven years old when it flowered first, and although I managed to fertilise R. blanda alba with its pollen, this hybrid has never produced seeds. Neither our native species nor their hybrids seem to take kindly to cultivation in pots.

I feel sure that under European conditions work of this kind could be carried forward far more quickly, and if some of the noted European Rose-breeders were to tackle this problem, I confidently believe that we would soon be rewarded with a race of garden Roses, descendants of our American and North Asiatic species, sufficiently hardy to withstand the most severe continental climate without protection. *F. L. Skinner, President of the Manitoba Horticultural Association.*

NOTICE OF BOOK.

Irises.

THIS little book* is intended primarily for American beginners in Iris growing, but it will no doubt be useful to those who are starting the cultivation of Irises in this country. There is a useful and interesting "Introduction," by Mr. Robert S. Sturtevant (Editor, American Iris Society), in which he states that Mr. Rockwell is just the man to write the book needed: "He knows Irises; but, quite as important, he knows what the gardener needs to know and how the information should be presented—conveniently and yet pleasantly." Incidentally, Mr. Sturtevant explains the task of the American Iris Society, and what he states of it, *mutatis mutandis*, may very well apply to our own Society.

Although a list of recommended kinds is given on pp. 79-82, the author observes (p. ix): "This book is designed to be used as a supplement to bulb catalogues and growers' lists. There you will find listed and illustrated, often in colour, not only the varieties of Iris mentioned in these pages, but the many fine new Irises which are introduced by dealers and Iris growers from season to season." The author gives full details as to the Iris itself—its varieties, requirements and enemies. He emphasises the good nature of the tall, bearded Irises as "being depended upon largely to take care of themselves," and concludes his chapter upon them: "The tall Bearded Irises are always a safe bet!"

---

* *Irises*, by F. F. Rockwell—The Home Garden Handbooks series—price 4s. 6d. Macmillan Co., New York.

The book is well furnished with illustrations, of which there are ten pages, besides insets in the text. These, although not large, will be very helpful to the tyro. The beginner in America seems to get more help and encouragement than he does with us, although it may be hoped that the expansion of the Iris Society, and the Wisley Trials, will make up our deficiencies. We congratulate Mr. Rockwell on a very useful, unpretentious, sympathetic piece of work.

NOTES FROM A NEW ZEALAND PLANT HUNTER.

(*Concluded from p.* 141).

On the upper slopes of the mountains the mixed Podocarp forest usually gives way to Beech forest, composed entirely of species of Nothofagus, with practically no undergrowth except the natural regeneration of the trees, while the sheltered watercourses abound in Plagianthus (Gaya) Lyallii, probably the finest white-flowered tree in New Zealand, with which is generally associated a rampant undergrowth of crown-forming Ferns, especially Polystichum vestitum.

Forest conditions (Fig. 78) usually dwindle away between 3,500 feet and 4,000 feet, to be succeeded for several hundreds of feet by a belt of scrub consisting of a very heterogeneous collection of shrubs. The gigantic family of shrubby Veronicas (or Hebe, as it is now the fashion to term some of them) forms a dominant note in these upland shrubberies. Although several well-defined species are to be met with, many of them are of local distribution, and all seem to hybridise freely with each other, a failing extremely common in all the larger New Zealand genera, with the result that natural hybrids abound throughout the country. Other members of the scrub community are Cassinia fulvida, many species of shrubby Senecios, some of which are most attractive; Gaultheria antipoda, G. rupestris, Dracophyllums in great variety, and many species of Coprosma—a most confusing genus of dioecious shrubs, the species being most easily determined by study of the differently coloured, translucent fruits which are borne in great abundance. Another genus which has many members noted for their fine flowers is Olearia. The more common species are O. arborescens, O. ilicifolia, and their suspected hybrid, O. macrodonta, O. moschata, and O. avicenniaefolia, and it may be interesting to note that O. Haastii, familiar in British gardens, is extremely rare in the wild state in New Zealand. Lycopodium volubile, a fine trailing plant which is greatly valued for decorative work, is an inhabitant of the sub-alpine scrub areas, where it scrambles over the shrubs, its growths sometimes attaining twelve feet in length.

Above the scrub belt are the open rocky moorlands which are the home of so many gems of the New Zealand flora, and where the scrub and moors meet is the abode of that aristocrat among Buttercups, Ranunculus Lyallii. This magnificent plant may be identified by its large, peltate, concave leaves forming huge saucers in which rain-water collects. In its native country, this plant is commonly termed the Mountain Lily which, like so many other common names, is quite inappropriate. R. Lyallii, in growth form, is not unlike the common Caltha palustris, having the same type of fleshy leaves and juicy stems. The beautiful, snow-white flowers are borne in great trusses of twenty or more, each being from two to three inches across, with a number of bright golden anthers. The glossy, dark green leaves, quite fifteen inches in diameter, and the flower-stems rising two feet above the leaves, form a most stately plant, so a colony of R. Lyallii swaying in the wind is well worth climbing 4,000 feet to see. Another species of Ranunculus worthy of a place in the garden is R. Buchanani, which also bears white flowers, but is much smaller than R. Lyallii, and has its leaves deeply segmented after the style of the typical Ranunculus leaf. Both these species were described and illustrated in *The Gardeners' Chronicle* of December 29, 1928. R. Godleyanus, a fine species confined to the Mount Cook district, has flowers of good size and a very fine deep yellow, while the light green, almost entire leaves are broadly oblong in shape. It is a handsome plant which has scarcely known the bonds of domestication, so far.

Among the numerous grasses in the alpine meadows are found the small white Viola Cunninghamii; several species of Gentians (all the New Zealand species are white, and G. corymbifera is the most noteworthy), Geum parviflorum, and the beautiful, large-flowered G. uniflorum; several species of Astelia, and the wonderful Celmisias, of which C. coriacea is probably the best of the genus, despite the fact that it is one of the most widely-spread. This desirable plant, at its best, forms an erect rosette of silvery, lanceolate leaves, from the centre of which arise several scapes bearing heads from three to four inches in diameter, with a golden disc, and long, narrow, pure white rays. This superb form passes by almost imperceptible gradations into smaller varieties. The other species of Celmisia are many and varied. The growth-forms vary from erect rosettes two feet high to tiny species with leaves only one-eighth-of-an-inch in length, which creep along the surface of the ground.

Bulbinella Hookeri, a fine, golden-yellow flowered Liliaceous plant, is abundant in the sub-alpine meadows throughout the South Island. The herbaceous Senecios are undoubtedly the most striking plants in many areas; of course, where Ranunculus Lyallii and some of the finer Celmesias are in evidence, the Senecios have, perforce, to take a minor position, but when, in sole possession of an upland valley, where there is plenty of moisture and good drainage, they light up the landscape with the abundance of their beautiful blossoms in a manner almost incredible to those who only know their dowdy relatives. The two aristocrats are Senecio scorzoneroides and S. Lyallii, the former producing white flowers, and the latter yellow. They hybridise freely and with little trouble one may have all gradations of colour between the two types.

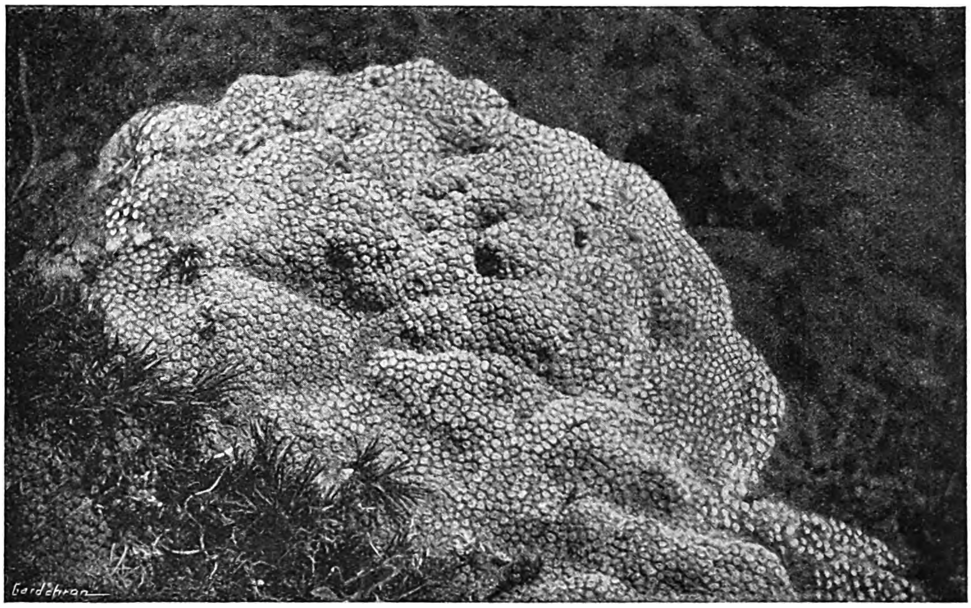

FIG. 80.—RAOULIA BUCHANANI.

The Aciphyllas are typical of mountain areas, the most abundant form being A. Colensoi, var. maxima, a plant of very stiff and rigid habit; the leaves are usually more or less bi-pinnate, the leaflets terminating in sharp spines; the dioecious inflorescences grow to over six feet high. There are many species of Aciphylla and they vary greatly, from the giant just mentioned to the tiny A. multisecta, which rarely reaches nine inches in height. An Antarctic genus of some note in the alpine flora is Ourisia. The common and beautiful O. macrocarpa has somewhat the habit of a Candelabra Primula. O. glandulosa and O. caespitosa are two beautiful carpet-forming species which inhabit moist, sunny moraines, where they produce numerous white blossoms during early summer.

The peculiar and well-known Vegetable Sheep, Raoulia species (Fig. 80) are inhabitants of dry alpine areas. These curious plants are very variable, the genus having been founded more upon habit than upon well-defined and distinctive characters. They are perennial herbs which bear numerous, densely-tufted heads, packed closely together, forming huge, rounded masses several feet long and sometimes over two feet high. When seen from a distance some of the species certainly look like sheep, so much so that shepherds have been known to send their dogs several miles to round up these "stray" members of the flock.

Owing to isolation, New Zealand, to which the nearest land-mass is Australia, over 1,000 miles away, has developed a very interesting flora, fully three-fourths of which is endemic. Many of these plants are justly famous in the horticultural world, but are extremely difficult to procure. It may be mentioned that so much as 10s. per ounce has been given for seeds of Ranunculus Lyallii within the past year.

Primitive New Zealand was either "bush" or tussock land, and in neither of these areas are there many striking herbaceous plants of high horticultural value. Therefore, it was not until the distant and inaccessible mountain valleys were explored that much of the country's interesting plants of horticultural value were brought to light.

There are many large genera in the mountain flora, and these seem to be in a state of movement, because although a number of well established species have evolved, there are still large numbers of unfixed natural hybrids, many of which are fairly widespread vegetatively, but seem incapable of producing fertile seeds. Therefore, it seems that natural hybridisation and inaccessibility are the two chief reasons why so many New Zealand plants have not yet come into general cultivation. *Dunedin.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XV.—At Camp II.

We stayed on at Chibaon until April 18, dispatching the loads as coolies came forward, which they did reluctantly. The air was thick with flying rumours; how there was an epidemic up the valley, and we were advised not to go on; how the young men of a certain village had barricaded the path and would not let us pass; and how another village had refused to supply us with transport or food—all designed to hamper, if not to turn us back. But as time went on, and little bands of coolies came and went with their loads, reporting that arrangements had been made for our reception at Meiliang, another two marches northwards, we paid less and less heed to this evil broadcasting, and went quietly on with our preparations.

During the fortnight I was here (April 5-18), we had six really wet days, and on six days practically no rain fell. When the mornings were fine and hot, a gale would spring up without warning in the middle of the day, blow for a couple of hours, and be succeeded by a brief thunder storm loosed from the western mountains. Thanks to our altitude, 3,250 feet, we escaped the horrors of the 'hot weather,' although even so, the temperature on fine days bounded up to 90° in the shade; but on wet or cloudy days it was only about 70°. The advantage of altitude was felt at night, the average minimum temperature being about 51°. We were camped in the midst of cultivation, in the heart of the village, and therefore we became 'the cynosure of neighbouring eyes.' Even our abridged toilets were carried out under close scrutiny, and it became embarrassing as well as disconcerting. There were always crowds of Mishmis with nothing to do except to watch us, although when we wanted coolies they just melted like clouds in the silent summer heaven; it was clear as daylight that they just disliked coolying, and, indeed, they had their own jobs to do.

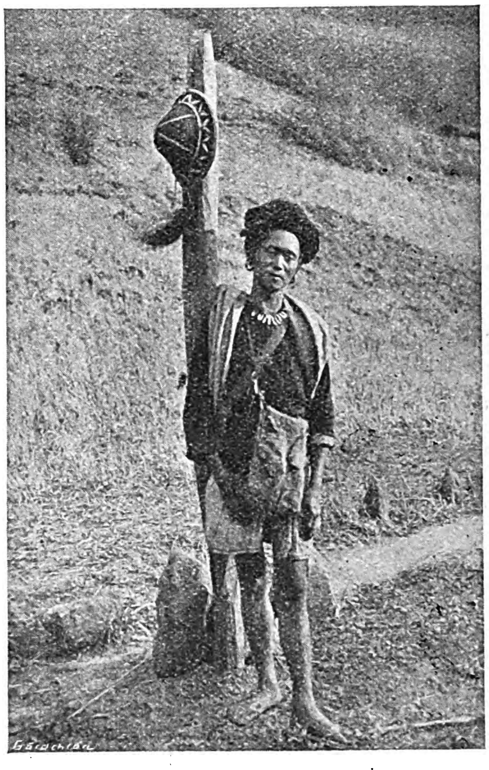

FIG. 81.—THE GAM OF MEILIANG.

He assisted Captain Kingdon Ward and is shown wearing a necklace of human teeth.

The broadly funnel-shaped valley which stretched away behind us to the horse-shoe ridge, was patched with cultivation, past and present. Most of the slope was clothed with high grass, and there were rougher parts, covered with trees. Two paths, both overgrown, led towards the forest, but it was a hot and tiring climb by either, sometimes through dense, secondary growth, and sometimes over newly-felled jungle, before one found oneself in the shade of the rain forest.

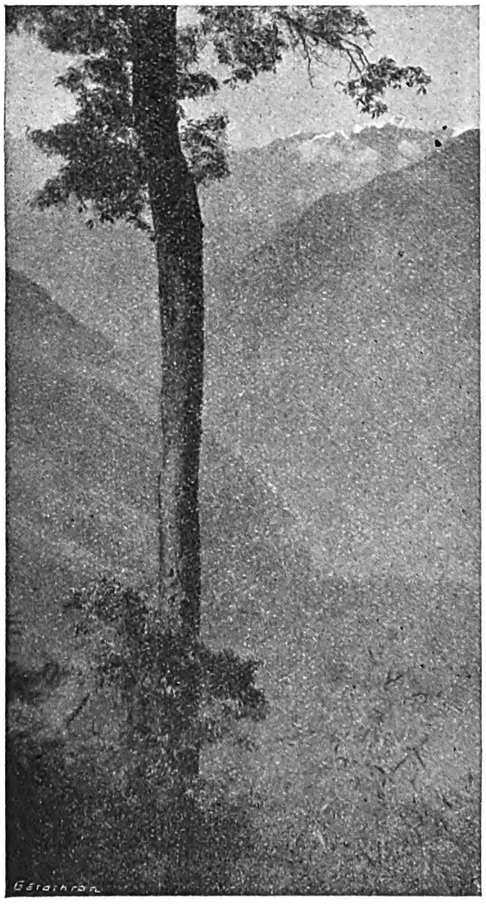

FIG. 82.—THE DELEI VALLEY, MISHMI HILLS.

Great activity prevailed in the fields, where weeding, burning and sowing were all going on feverishly. At this season, the Opium and Pea crops were ripe. Every hut had its Poppy garden of sleep, carefully fenced in; the flowers were nearly all white, a few red. The Peas were a tall variety with purple flowers like the wildest of the wild; but they were quite good to eat. For the next few weeks we almost lived on Peas and Sweet Potatos, and it was a bad day for us when the latter were finished. Eggs could sometimes be obtained, but fowls rarely. The fact is, when a Mishmi falls ill, he slays a fowl, and eats certain parts of its anatomy, which is supposed to cure him. Thus a fowl is a potential drug in case of disease, and as every man is his own doctor, few were found willing to supply us with food from the family pharmacopoeia, even at an exorbitant figure. Eggs, when available, were comparatively cheap, and we soon discovered why. We observed that they were always what are called 'shop eggs,' or just 'eggs,' at home—for we taught the cook to detonate those which had an electioneering look about them, at a safe distance; in short, the wily Mishmi never parted with an egg until the hen had given it up as a bad job. It was a well-hatched plot!

The village vegetation comprised Peach trees, Bananas, clumps of Bamboo, a few small Palms, and Albizzia Julibrissin, the latter very common wherever there were crops, and now in full bloom.

Mishmi huts (Fig. 84) are long and low and dark, built of Bamboo and thatched with grass; they are raised from the ground on piles, the space beneath being used as a pig-sty, while under the eaves, baskets are suspended for the family fowls. A few cattle are also kept, although for what purpose I could never discover; probably they are sacrificed in times of crisis, and used as medical comforts.

The secondary growth was a wild tangle of grass and shrubs, including the following:—Edgeworthia Gardneri, Alnus nepalensis, Ficus Cunia, species of Pieris and Gaultheria, Luculia gratissima, several species of Rubus, Buddleia, Saurauja, Coriaria, and Osbeckia; also the following climbing plants among others:—Smilax, Sabia, Crawfurdia, Porana, various Leguminosae, Menispermaceae, and so forth. The growth was very thick and quite impossible to penetrate. The temperate rain forest, on the other hand, is fairly open, there being comparatively little undergrowth, and that chiefly of Ferns and small Monocotyledons. Climbing plants are not nearly so abundant here as they are in the sub-tropical jungle below, although the epiphytic flora is probably as large and varied.

On April 8, I made an excursion into the forest, and on the 11th, Buttercup and I went for a long climb up the ridge, the day being fine and very hot. Following the path I had discovered, we made straight for the point I had reached on my first evening at Chibaon, and then turned up the mountain. At once we began to find Rhododendrons in promising variety. The first was a medium-sized tree 'Irroratum,' with flowers of daring purple, rasped with clusters of darker stars; not only is such a blackberry-and-apple colour unique in the section 'Irroratum,' but rare in the whole range of Rhododendron, hybrids included. In high lights, the flowers took on a more crushed-strawberry tint; but the shade varied a good deal, as did the spotting. To be seen at its best, this species requires a strong light, which, of course, it seldom gets inside the forest; but it showed up well along the crest of the ridge; the flowers last well, and the tree blooms over a period of four weeks, more or less. I suspect that an 'Irroratum' collected in the Seinghku valley in 1926, not seen in flower, is the same species; on that occasion I got very few seeds of it, as it had misflowered badly.

Just coming into bloom was a 'Thomsoni' Rhododendron with astonishing leaves nearly a

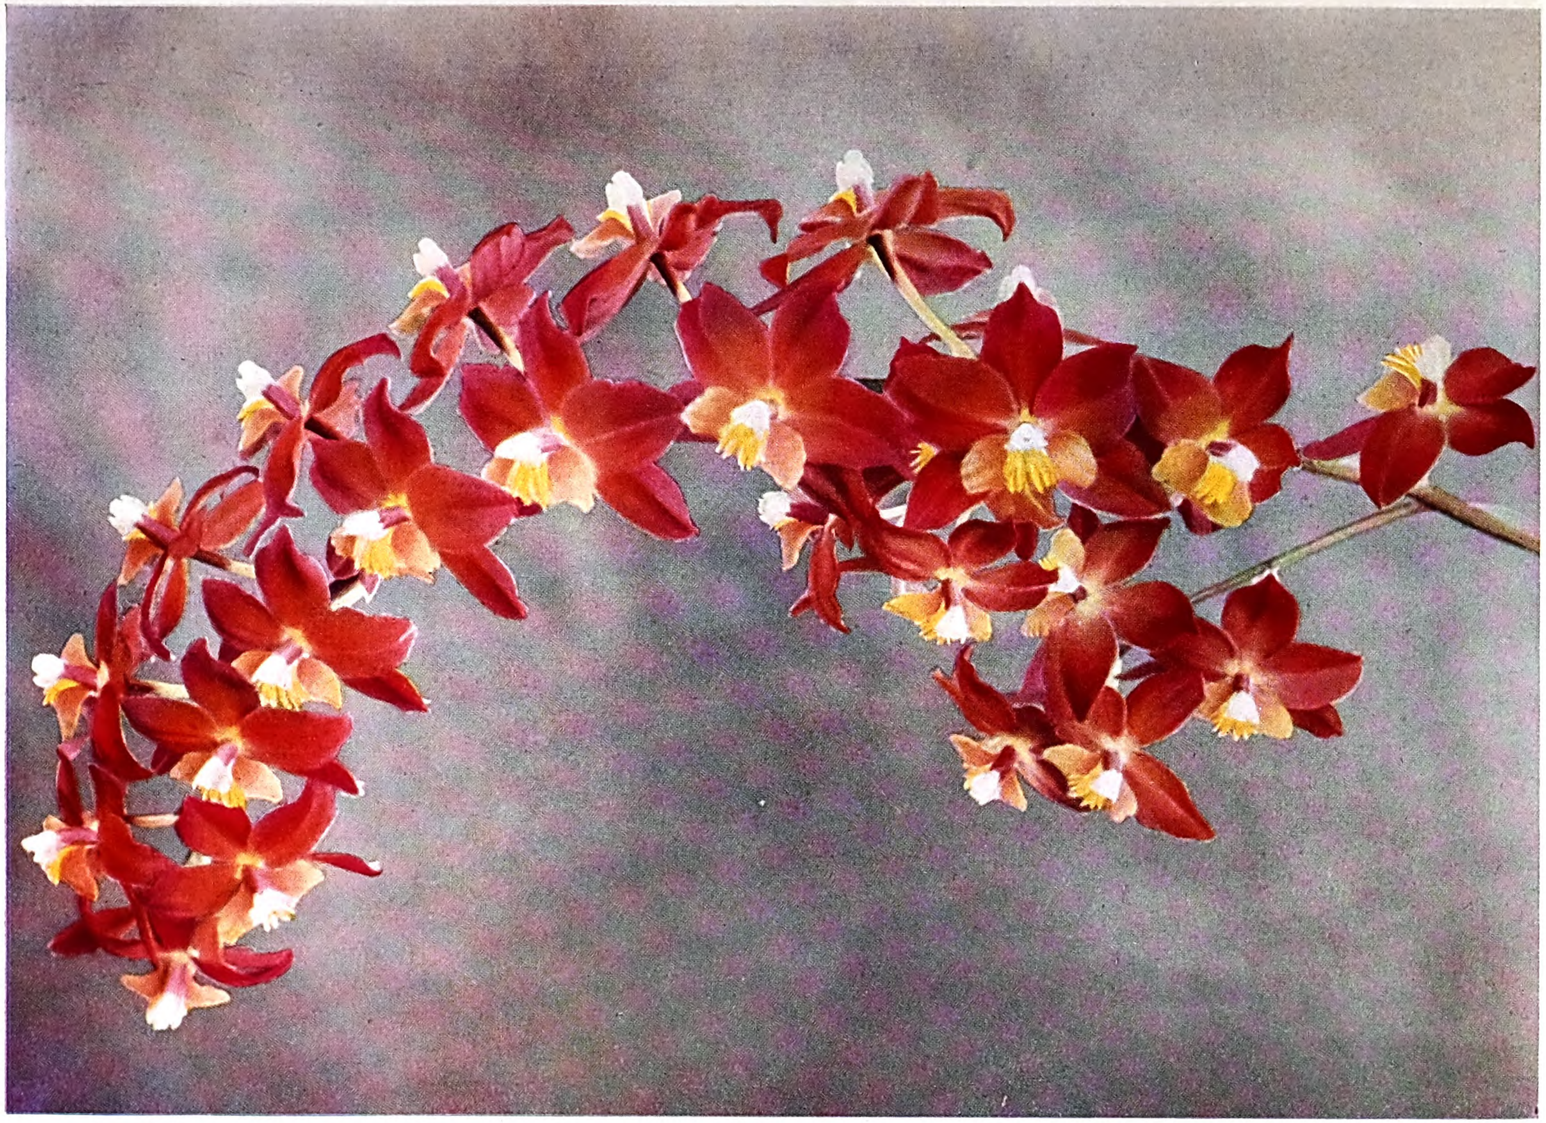
Supplement to "The GARDENERS' CHRONICLE."



ODONTIODA LAMBEAUIANA, WESTONBIRT VAR.

foot long and five inches wide; the buds had a hint of pink in them, but when 'Big Bill Thomsoni' opened, the enormous bells were virginal-white, in trusses of three or four—there was no room for more. Big as the leaves were, they did not hide the flowers, and except in the depth of the forest, the bush did not become a tree; it was, in fact, a very manageable size, and its charms were enhanced by the smooth, tawny-purple bark and weirdly contorted branches. 'Big Bill Thomsoni' is a fine Rhododendron, and, moreover, it was the first of several which I had not met with in the Seinghku or Di Chu valleys during my expedition of 1926; as my alpine camp in the Seinghku valley was barely sixty miles distant, in an air line, this was matter for congratulation.

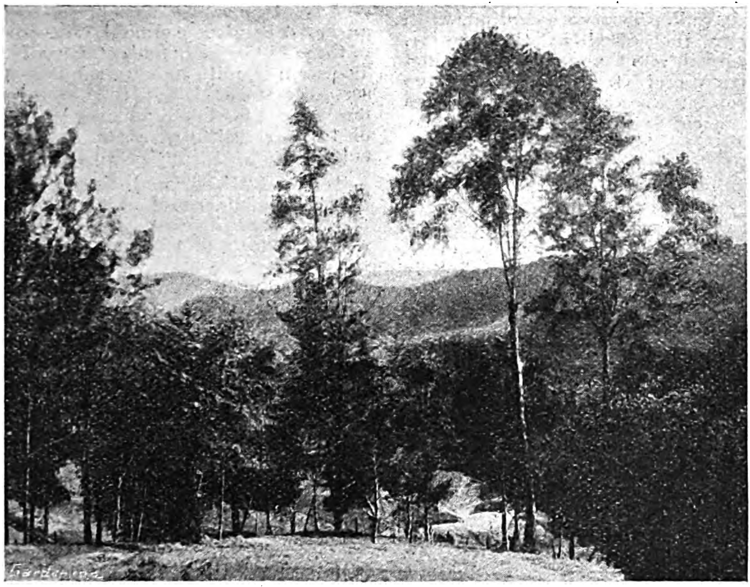


FIG. 83.—A HILL STATION IN ASSAM.
The trees are alien—Grevillea robusta and Coniferae.

The next Rhododendron met with on the ridge looked very much like R. bullatum, but it was nearly all over; eventually I found one plant in bloom, with very fragrant, white flowers, although the leaves of the 'Edgeworthii' and 'Maddeni' series are so different, woolly in the former, lepidote in the latter, the flower structure is very similar in both, and the series are undoubtedly very closely allied.

Inside the forest, R. arboreum was flowering in lurid splendour, and not many days later the 'Stamineum' broke into a yeast of white foam. This last, which recalls R. Mackenzianum, (although that has pinkish flowers) is disappointing. As a forest tree it is gawky, and the queerly shaped flowers, for all their elegant purity and dainty fragrance, fall too soon; the trusses, too, are meagre. Even so, viewed from the outside, across a glen, it shows up as a fine dome of soft blossom. But it is undoubtedly at its worst in the forest, as are all its kith and kin; the pinched flowers, in floppy trusses, the whorled leaves of an everyday shape crowded at the ends of the bare branches, and the torn, papery bark, [all help to give it an 'anyhow' look. Growing on a sunny or wind-swept ridge, however, the long, lean branches are telescoped, and the awkward, leggy-looking tree becomes a compact shrub with a firm contour; then, when a mantle of blossom surrounds the whole, with the scarlet of dead leaves and the purple plumes of the newly-born showing through, this 'Stamineum' takes on an entirely different and pleasing appearance. And that undoubtedly is the way to grow any 'Stamineum' whose characteristic peculiarities otherwise are its undoing. Unfortunately, as a family, they are soft, and even in a sheltered position cannot withstand the home climate; small chance then of their surviving under conditions which would keep them clipped and garnished! *F. Kingdon Ward.*

(Alt. 3,000 feet.)

NOTES FROM WISLEY.

In the matter of frost, Wisley rarely escapes lightly, whether in winter or late spring and in spite of its position it often experiences lower temperatures during cold spells than do much more northerly districts. During the recent period of exceptionally cold weather so many as 33° of frost were registered on the grass and well over 20° in the screen. The effect of this is naturally to be seen among the less hardy plants in the gardens, and considerable withering of foliage is noticeable in the case of Bamboos, and rather delicate shrubs, such as Abelia and Ceanothus. However, so far as can be seen at present, the mortality is by no means so high as might have been expected, and it is noteworthy that upon the Rhododendrons, including many somewhat tender species, the effect of the frost has been extremely slight. Among the Heaths, the flowers and foliage of certain large specimens of Erica lusitanica have been blighted, but the several good varieties of Erica carnea which are in bloom, such as E. c. gracilis and E. c. King George V, have been scarcely affected. Many varieties of E. mediterranea, one of the best of which is Brightness, are also flowering well. Many months must elapse before the flowering of the Lings, but Calluna vulgaris alba var. rigida gives a very good imitation of being in bloom, owing to the fact that it still retains its old flowers, the petals of which remain silvery-white and show up well against the fresh green foliage.

Snowdrops and Leucojums are still almost the only bulbs in flower in the wild garden, but shrubs such as Hamamelis mollis and the more vigorous H. japonica var. Zuccariniana help to make up for the general deficiency of bloom. The foliage of several Barberries has been damaged by frost, but that of Berberis concinna is still attractive although its leaves, which are crimson above, are beginning to fall and thus to show their white reverse. A few of the Oaks have retained their foliage, and among them Quercus coccinea, Knaphill variety, the leaves of which still betray a strong tinge of red, is outstanding.

Plants in the alpine house, which have been without heat throughout the cold spell, have in some cases suffered rather badly, and the blooms of Primulas in flower, such as Primula Forbesii and hybrids of Primula Juliae, have been withered, many flowers of the latter turning bright blue. The effect of the frost is also painfully visible in the case of plants of Haberlea, and even of Morisia hypogea, the flowers and foliage of which have been scorched. The early-flowering Saxifrages, however, have withstood the trying conditions conspicuously well, and the pretty, snow-white blooms of Saxifraga Burseriana tridentina are unblemished, while those of S. Burseriana major and S. B. minor are about to open. Kabschia Saxifrages which are also coming into flower include the charming little hybrid Perle Rose, with clear pink flowers, and the Cilician Saxifraga Kotschyii, with lemon-yellow blooms. In addition to Saxifrages, the pretty dwarf Thrift, Armeria caespitosa, which has been producing occasional blooms during the winter, is now commencing to flower a little more freely. The Crocuses in the frames outside the alpine house continue to bloom and among them the yellow flowers of Crocus minimus are noticeable.

In the heated greenhouses Lachenalias sent to Wisley for trial and comparison are in flower. Lachenalia pendula superba, with red flowers, is nearly over, while the yellow-flowered Arabia and Spa are not yet at their best. Varieties of this flower but recently received which show promise include Chaffinch and Brightness. In the same house the standard collection of Freesias should be in bloom very shortly and will afford means for comparing many new varieties. A Fuchsia trial is also in progress, but the plants will not be at their best until July or August. In an adjoining house is to be seen a trial of Dwarf Beans, which were sown in the middle of January, and which should be ready to pick at the end of March. Most of the fifty-eight varieties on trial appear very healthy and robust, particularly the variety Helmingham Early Prolific, which has very large leaflets. There is a noticeable tendency among some varieties, as, for instance, Ne Plus Ultra, to climb, in distinct contrast to the stocky habit of varieties, such as Osborne's Forcing.

One of the most important trials to be held in the open at Wisley this year is that of annual Asters, of which five hundred stocks have already been sent in. The number of sections or classes into which this flower is being divided by seedsmen is growing rapidly, and in some cases the total amounts already to thirty or forty. This trial may, perhaps, afford the means of determining whether the strains are sufficiently distinct to justify so many classes.

It may not be realised that some of the seeds raised at Wisley are grown in the laboratory itself, as, for example, those of the Chinese Primula Littoniana, with its mauve and scarlet flowers. Seeds of the latter are germinated on moist blotting paper kept in the light and at a temperature of 50° to 60°. After about a fortnight, the tiny seedlings are pricked out, with the aid of tweezers, into seed-pans. *J. E. Grant White.*

NOTES ON SOME BRITISH PLANTS.

MALVA SILVESTRIS VAR. VIOLASCENS.

MR. H. WHITLEY, of the Primley Botanic Nursery, Paignton, South Devon, collected, in Somerset, a Mallow which is being distributed in the horticultural trade as Malva "Primley Blue." Flowering specimens were received at Kew in October, 1928, and have not been exactly matched. There is no doubt that the plant is to be classified under the Linnean M. silvestris, but it does not exactly agree with any specimens at Kew, nor does it coincide with any of the described varieties, so far as can be ascertained. It is, therefore, described here as a new variety of the species.

M. silvestris, L., var. violascens, Turrill, var. nov. Planta perennis ad 1·2 *m. alta. Rami petiolique pilosi, pilis et simplicibus et stellatis instructi. Folia numerosa, laminis usque ad* 3-4 *cm. longis et* 4·5-6 *cm. latis, lobis usque ad* 1-1·5 *cm. longis et* 1·5-2·5 *cm. latis. Calyx* 9 *mm. longus. Petala circiter* 2 *cm. longa,* 1·4 *cm. lata, violascentia. Carpella glabra.*

The colour of the petals on the living plant was matched with Ridgeway's Dauphin's-violet (*Color Standards and Nomenclature*, 1912, Plate xxiii), and that of the veins of the petals with dark, dull, bluish-violet (Plate xxxvi).

GERANIUM ENDRESSII VAR. ARMITAGEAE.

In the *Journal of Botany*, lxvi, 44, 88 (1928), an account was given of G. Endressii, J. Gay, as it occurs in Cornwall. Two varieties, one with two forms, were recognised in the species, which, it was agreed, was taxonomically distinct from G. striatum and G. nodosum. I have since received specimens and living plants of a series of Geranía cultivated by Miss Armitage, Dadnor Garden, Herefordshire. An examination of these specimens enabled me to name all except two. Of these, one, on morphological grounds, was judged to be a hybrid between G. Endressii and G. striatum, and the other is considered to represent a new variety of G. Endressii. It is impossible to decide definitely if hybridisation has or has not been a cause of the origin of this variety, but the facts suggest gene mutation, perhaps induced by conditions of cultivation.

Geranium Endressii, J. Gay, var. Armitageae, Turrill, var. nov. Petala oblanceolata apice rotundata, obtusa, vel subacuta integra vel leviter crenulata, haud emarginata, 1·6-1·7 *cm. longa,* 4-4·5 *mm. lata* ; *stamina fertilia, antheris apiculatis.*

Cultivated by Miss E. Armitage, Dadnor Garden, Herefordshire. The petals in the living state are deep rosy pink.

LISTERA CORDATA, R. BR., IN HANTS.

In Townsend's *Flora of Hampshire*, ed. 2, 416 (1904), this species is recorded from "near Bournemouth," and from "Branksome woods." E. F. Linton, in his *Flora of Bournemouth*, p. 205 (1900), quoting the same localities, states : "The fact that this species, so unexpected in a county on the south coast, has been rediscovered 'near Bournemouth,' but on the Dorset side of the border, renders it very probable that the two discoveries represent only one station. It is much to be desired that the plant should be found in Hants., and there are suitable woody slopes about Bournemouth, Herne, etc., where it might be reasonably hoped for ; but until it has been so detected, it cannot now be claimed as a Hampshire plant."

It is therefore worth recording that a specimen of Listera cordata collected near Brockenhurst, Hants., June, 1927, by R. Findlay, has been received at Kew. The specimen is a small one and the flowers are in bud, but there is no doubt of its identity.

VIVIPARY IN DACTYLIS GLOMERATA, L.

Viviparous specimens of the common Cocksfoot are received at Kew from time to time. The majority show the development of vegetative shoots in the inflorescence, correlated with the growth of the glumes into green leaves. A specimen received through Mr. E. Thurston, however, is so extraordinary as to warrant record. It consists of the upper part of one plant and evidently represents a branched inflorescence with a subtending leaf. The lowest branch of the inflorescence consists entirely of vegetative shoots with fairly well developed green leaves. The second branch and the terminal part are dense aggregates of viviparous shoots from which grow out much reduced partial inflorescences on slender stalks. These partial inflorescences have normal glumes with perfect florets. The specimen was collected by W. Tresidder, at Pentewan, Cornwall, November 17, 1928.

In some localities, in some seasons, D. glomerata has two flowering periods—early summer and autumn. In late-flowering specimens, especially in wet autumns, some degree of vivipary is common. It is possible that the specimen here described was one whose late inflorescence-bearing stem became bent over and that proximity to damp soil stimulated vegetative growth which, however, did not entirely prevent the formation of partial inflorescences. *W. B., Turrill, D.Sc., Kew.*

THE SAFFLOWER.

THE Safflower (Carthamus tinctorius, L.), or Bastard Saffron, although so named after Meadow Saffron (Colchicum autumnale, L.), is in no way related to it botanically. It is a member of the Natural Order Compositae, and somewhat resembles a Thistle in appearance. A handsome annual, it attains to a height of three feet or more under favourable conditions. The stem is quite smooth, the leaves oblong and serrately prickled, and the flower-heads, which are rather more than an inch long, are made up of tubular florets of a brilliant orange to red colour.

Schweinfurth has distinguished a variety, inermis, which occurs in Egypt, differing from the type in having the lower leaves less spinulous, and in other minor characters. The flowers of the variety are stated to be frequently orange, red apparently being the normal colour for those of the type.

Carthamus tinctorius has been cultivated so extensively, not only in the east, but also in southern Europe, that it is difficult, if not impossible, to say exactly where it is native. In his *British Plant List*, Dr. Druce gives Abyssinia as the home of the plant, while some other authorities have described it as native to southern Asia. The plant has been cultivated in England, and is apparently easy to grow, the seeds being sown in the spring in a gentle bot-bed, and the plants afterwards transplanted; but very few, if any, are grown in England to-day. Occasionally, solitary specimens may be found growing on waste lands in a pseudo-wild state. Such plants are often stunted in their growth.

The plant is still widely cultivated in Asia and Egypt, and yields a number of products of economic importance. The most interesting of these is the red dye, carthamine, extracted from the flowers. The tinctorial powers of the plant have been recognised from very early times, and the plant, as a consequence, held in high esteem. The dye, indeed, is excellent in colour, although somewhat fugitive ; but its extraction is so difficult that, in Europe, at any rate, its use has been completely superseded by that of coal-tar dyes. Safflower-red, however, is still in big demand in the east, being used in Japan and elsewhere for the preparation of rouge, as well as for various other dyeing purposes.

As a matter of fact, the florets contain two colouring matters, a yellow one present up to about thirty per cent., together with the red one, carthamine, which occurs to the extent of only about 0·5 per cent.

To obtain the valuable red dye, the flowers have first to be thoroughly treated with water, perferably containing a little vinegar, to remove the yellow colouring matter. The residue is treated with a solution of washing soda, in which the red dye dissolves. Bleached cotton is then introduced into the solution and acetic acid (vinegar) added. This causes the whole of the dye to be deposited on the cotton, from which it is then extracted by means of a fresh solution of washing soda. It can be re-precipitated from this solution by means of a weak acid, such as tartaric acid, filtered off and further purified, or deposited direct on to chalk or talc in order to make rouge. Owing to their tinctorial properties, the florets have been used as an adulterant of Saffron.

The seeds of the Safflower are rich in an edible oil, and have been put to many uses. Not only are the seeds employed as poultry food, but they are also made into cakes for cattle, being pressed for this purpose either whole or after husking. The former type of cake contains a higher percentage of soluble carbohydrates than the latter, but a less proportion of albuminous compounds and a considerable amount of woody fibre. The cakes keep well, and cattle, which do not take to this dietary at first, are stated soon to become accustomed to it.

The oil may be obtained from the seeds by expression. In India, it is employed in the preparation of an oil used to preserve leather vessels, ropes, etc., from the rotting action of water. In Egypt a burning oil is stated to be obtained from Safflower seeds.

It is doubtful whether an attempt to re-introduce the cultivation of Safflower into England would prove beneficial from an economic point of view, but the rather unusual colour of the flowers renders the plant attractive, on which grounds, if on no other, it deserves to be better known. *H. Stanley Redgrove, B.Sc.*

NURSERY NOTES.

BICENTENARY OF MESSRS. DICKSONS AND CO., OF EDINBURGH.

The bicentenary of a Scottish seed and nursery firm is no ordinary event; in fact, there are but two firms in Scotland which have reached their second hundredth year: Messrs. Austin and McAslan, in the west, and Messrs. Dicksons and Co., of Edinburgh, in the eastern part of the country.

The Dickson firm originated at Hassendeanburn, near Hawick, in 1729, and soon after 1764 the business was transferred to Edinburgh. The founder of the firm was one Archibald Dickson, who was succeeded by his son, Robert Dickson, and the business remained in the hands of the Dickson family for well over a century. It is interesting to note that one member of the firm, Mr. Walter Dickson, was made a burgess and freeman of the burgh of Canongate in 1787, and that another member of it, Mr. Andrew Dickson, was appointed the treasurer of the Caledonian (now the Royal Caledonian) Horticultural Society when it was founded at Edinburgh in 1809, in which capacity he continued to act for well over twenty years. The joint-secretaries appointed at the same meeting were the distinguished Edinburgh horticulturist, Mr. (afterwards Dr.) Patrick Neill, of Canonmills House, and Mr. Walter Nicol. Another member of the Dickson firm, Mr. Thomas Dickson was elected as a Councillor of the Society at the same meeting, which was held in the Physicians' Hall, George Street, on the site of which the head office of the Commercial Bank of Scotland, Ltd., now stands.

When the Dickson business was transferred from Hassendeanburn to Edinburgh, a seed shop was opened at Shakespeare Square, which occupied the site of the present General Post Office, and large nurseries were commenced at Leith Walk, which then consisted for the most part of open fields, with isolated blocks of buildings at intervals. Here many of the leading Scottish gardeners of that time received part of their early training, and to 1, Waterloo Place, which was acquired by the firm as their business premises after the demolition of Shakespeare Square had been decided upon for the erection of the new post office, hundreds of young Scottish gardeners from all parts of the country gravitated on term days to find employment in the splendid gardens of the many beautiful mansions of Scotland, England and Ireland.

It is also interesting to note that the greatest of all Scottish authors of horticultural, agricultural and arboricultural literature, John Claudius Loudon, who was born at Cambuslang in 1783, and whose father was formerly a farmer in the neighbourhood of Edinburgh, spent some time as a pupil of the Dicksons at the Leith Walk Nurseries, where he carried out some of his horticultural experiments, before he removed to London, there to commence his wonderful career as a landscape gardener and author, in 1803. After occupying the nurseries at Leith Walk for over a century, in 1875 the proprietors of the ground, the Governors of George Heriot's Hospital, notified Messrs. Dicksons and Co. that they would resume possession of the land in that year, and this compelled the firm to find new ground for their nurseries, which they were fortunately able to procure in the vicinity from Mr. Balfour, of Pilrig.

In 1800, according to Grant's *Old and New Edinburgh*, proposals were made to convert the adjoining lands of Redbraes into a "Vauxhall," but the scheme fell through, and the ground was soon afterwards acquired by Messrs. Dicksons as nursery ground. The nurseries at Pilrig and Redbraes were carried on uninterruptedly for a number of years after 1875, but in 1891 the necessity for acquiring other ground arose through much of the Pilrig nursery being appropriated for railway extensions, and the firm decided to transfer their nursery to another site where disturbance of this nature would be much less likely to occur. In this year, therefore, a move was made to a new site on the lands of Craigmillar estate, on the southern boundary of the city, where about one hundred acres were obtained, and which now constitute one of the largest nurseries in the country. In 1922, having acquired much more commodious premises at 20, Charlotte Square, the firm vacated the shop and offices at 1, Waterloo Place, which had been their headquarters for over a century, and transferred to the former address, whence the whole of the seed and nursery business is now carried on.

There does not seem to be any record of when the last of the Dickson family ceased to be connected with the firm, but in the first half of last century Mr. James Alexander the elder, a native of Banffshire, became sole proprietor of it, and some time after this he was joined by two brothers, Messrs. James and William M. Welsh, and still later by his nephew, Mr. James W. Alexander, who died in 1890. Afterwards, Mr. W. H. Massie, who died in August last, was taken in as a partner, and in 1913, Mr. John Halliday Alexander, a son of the late Mr. James W. Alexander, entered the firm, and at present the two partners are Mr. J. H. Alexander and Mr. James Welsh, a son of the late Mr. W. M. Welsh.

Such is a short resumé of the history of one of the best known and most outstanding seed and nursery firms in Scotland.

THE NATIONAL IMPORTANCE OF FRUIT-GROWING.—I.

In a series of four short articles, written as a result of certain rather misleading views stated in the press, and, in particular, in a certain paper recently read before the Farmer's Club, it is proposed to indicate the present economic position of the fruit-growing industry in this country, considering first, the question of the internal demand for fruits; secondly, the possibility of increasing the supply; thirdly, the costs involved, and lastly, a general survey of the position.

While in no way wishing to discourage fruit-growers, or potential fruit-growers, it is only prudent to draw attention to such authoritative figures as are available. At the same time it should be noticed that the depression in agriculture which undoubtedly exists, is less in this than in any other European country, except Poland. The index figure for ordinary agricultural commodities in 1928 was 145, as against the figure for the cost of living, which was about 160. The figures for top fruits, such as the Apple, are similar to that for the standard of living; while those for soft fruits are, in many instances, greater. It is to be seen, therefore, that fruit growing, if depressed at all, is less so than ordinary agriculture, and that soft-fruit growing, so far from being depressed, is in a better position than top-fruit growing, and a considerably better one than ordinary agriculture.

In a paper read before the Farmers' Club on February 4, 1929 (see *The Gardeners' Chronicle*, February 16, p. 125, and February 23, p. 146), Mr. Seabrook stated: "The total consumption of fruit in England is put at £200,000,000" per annum. It seems that in this respect Mr. Seabrook must have been misinformed, since, in the *Report* of the Imperial Economic Committee, 1926, it is stated "the total imports for 1925 are £44,800,000." To this figure must be added the value of home produced fruits consumed in England, which, from the *Census of Production for England and Wales*, 1925, amounts to £9,720,000. If a further allowance of £3,000,000 be made for fruits produced in Ireland and Scotland, the total value of fruits consumed in this country is £57,520,000, and not £200,000,000, as Mr. Seabrook represents.

On examination of the figure of £44,800,000 given by the Imperial Economic Committee, it is found that £31,000,000 is accounted for by Oranges, Lemons, Grapes, dried Currants, Sultanas and other tropical fruits. Included in the balance is the sum of £5,000,000 for canned fruits, some of which cannot be replaced by home production, leaving £8,800,000 for Apples, some of which, when imported, are out-of-season fruits. If to this figure be added the value of fruits produced in England, Ireland and Scotland, the total value of hardy fruits consumed in this country is found to be £21,520,000. Of this total, it has been shown that of fruits capable of being produced in England, £12,720,000 worth is produced in the British Isles and £8,800,000 elsewhere. There would seem, therefore, to be, financially, a relatively small market to be captured by the English fruit-growers in spite of Mr. Seabrook's more optimistic implications. *A Norfolk Grower.*

(*To be continued.*)

THE GENUS PRIMULA.

(*Continued from p.* 143).

LEPTOPHYLLA (Craib). Spurge-leaved P.
(Petiolaris-Davidii.)

A perennial species with at hick, woody rootstock clothed at the base with numerous membranous, persistent scales. The thin, rigid leaves, in tufts, have oblong-elliptic, elliptic, oblong-egg-shaped, or egg-shaped blades, rounded at the tip and tapering to a wedge-shaped, winged stalk at the base, in all about five inches long; margins furnished with narrow, blunt teeth which are very minutely fringed; upper surface green, more or less smooth, underside covered with minute down. Flower stems one or two in number, three to six inches tall, bearing from five to nine blossoms, bluish-purple in colour, the shape and size of which does not seem to have been recorded. Flowers in May. Not in cultivation.

Grows in open situations on the Plateau of Tsetchoupa, in Yunnan, western China, at about 9,500 feet above sea-level.

Culture: As for other members of the section Petiolaris.

LEUCANTHA (Balf. f.). Milky-flowered P.
(Candelabra.)

A very beautiful Candelabra Primula, with a tuft of lance-shaped or oblong-oval, blunt leaves from six to nine inches long, gradually tapering to a scarcely distinct, winged stalk; margins undulate and furnished with small, hooked teeth; both surfaces the same tint and sprinkled with numerous minute, meal-producing, glandular hairs. Flower stem nine to sixteen inches tall, stout, coated with white meal towards the tip and bearing several superposed umbels of white, golden-eyed blossoms, on slender, spreading stalks about three-quarters-of-an-inch long. Corolla about three-quarters-of-an-inch long, with egg-shaped lobes; tube longer than the calyx. Flowers in June.

Grows in moist alpine pastures, on the mountains around Muli, in south-western Szechuan.

Culture: As for P. Beesiana, of which it is considered a sub-species.

LEUCOCHNOA (Hand.-Mazz.). White-stalked P.
(Nivales.)

A robust, perennial species, with a stout rootstock which produces a tuft of narrowly lance-shaped, pointed, fleshy leaves, four to eight inches long, with revolute margins and indistinct, broadly-winged stalks; upper surface more or less smooth, underside coated with white meal. Flower stems eight to fourteen inches tall, one to three in number, stout, bearing one or two superposed, many-flowered umbels of purple blossoms, on down-curved stalks, half- to one-and-a-half inch long, coated with white meal. Corolla flat, about three-quarters-of-an-inch across, divided into five broadly oval, blunt lobes fringed with minute, glandular hairs; tube more or less cylindrical, about three-quarters-of-an-inch long. Flowers in June and July.

Grows in decaying vegetation on the mountains of south-western Szechuan, at 10,000 to 11,000 feet above sea-level.

Culture: Rich fibrous loam, leaf-soil and powdered limestone, in a damp, shady spot, should suit it. *A. W. Darnell.*

(*To be continued.*)

HOME CORRESPONDENCE.

Gardeners' Pay and Status.—In the issue of *The Gardeners' Chronicle* for February 16 (p. 125), your correspondent, *H. B. O.*, states that had I been present at the Annual Dinner of the Professional Gardeners' Association, held at Leeds on February 2, I should have changed my opinion regarding the absence of an organisation worthy of the name to protect gardeners' interest. Since my note appeared in your columns, I have received a letter from the Secretary of the Professional Gardeners' Association, together with literature explaining the aims and objects of the Association. I gladly withdraw my previous statement, but venture to suggest that there are a great many gardeners who, like myself, had scarcely heard of the P.G.A., if at all, which fact stresses the need for the Association to advertise itself among gardeners. After perusing the literature, I feel sure that such an organisation would be welcomed and supported by both gardeners and employers, and no one will deny the need for it. Its object should be sufficient to guarantee the support of all interested in horticulture. In conclusion, I hope *B. C.* took the advice of Mr. Platton, and scanned the situations vacant columns, as some of the advertisements make one wonder if certain advertisers really expect to get a competent gardener at wages little better than those paid to labourers. *J. Batty, Tyn-y-Coed.*

Freesias from Seeds.—Your correspondent *G. B.* (p. 96), states that Freesias in their natural state are great lovers of moisture, and are often found growing on the bank of a running brook or stream. I presume *G. B.* has seen them growing thus in their native land. I have often wished to meet someone who knows Freesias in their native land, so that I could learn all about their climatic and soil conditions. I have always understood, however, that Freesias grow in a somewhat dry and hot part of the country, and that the natural water supply is rather uncertain. Their behaviour under cultivation rather points to this, and the conformation of the plants' growth below the soil rather leads me to believe that they are prepared to fight dry conditions. Under cultivation, I have never found them to require frequent watering—in fact, they are never watered unless the soil is really dry, and in the early stages of growth very careful watering is required. As to compost, I never use leaf-mould, and always think manure is best omitted, certainly in the case of young seedlings, which do not require feeding so early in life. Surely four seeds in a six-inch pot is not enough. I would certainly sow ten. I always find it better to under-pot rather than over-pot Freesias. *G. H. Dalrymple, Bartley.*

Woolly Aphis.—On p. 127 of *The Gardeners' Chronicle* for February 16, 1929, Mr. H. H. Cook, writing on the above pest and various remedial measures, states, "So far, I have not seen a painter's blow lamp advocated. Yet it is a most effective means of eradicating this pest above ground." I have been using this method for about fifteen years. I conducted a gardening class for several years at the Redditch Technical School, where I used to advocate this method and when I gave my lecture, "Aphides: their Habits, Customs and Natural Enemies," to the Fellows of the R.H.S. on July 27, 1920, I think I mentioned this method. I also advocated the use of creosote oil for spraying. As regards the blow lamp, in the hands of an intelligent person, I do not think there is anything better than this for destroying woolly aphis. I have used it many times, and also for canker wounds, and for mealy bug on the Grape vine during the dormant winter period. Aphides have been one of my "pet" subjects for observation and research for many years. *J. G. Blakey, Bromsgrove Road, Redditch.*

Notable Successes with Vegetables.—In the history of horticulture many remarkable exhibits have been recorded by well-known private growers, but it is doubtful whether there have been any results so outstanding as those achieved during the past year (1928) by the Hon. Vicary Gibbs, V.M.H., of Aldenham House, Elstree, Hertfordshire (gardener, Mr. E. Beckett, V.M.H.), in his several and varied displays of vegetables, exhibited at the great shows of the Royal Horticultural Society and at other exhibitions in the provinces. Briefly the more noteworthy exhibits were as follow:—CHELSEA, MAY 23—Royal Horticultural Society's Great Show: Collection of vegetables arranged on a space thirty-three feet by twelve feet. The R.H.S. Gold Medal was awarded for this exhibit (Fig. 86); also the Sherwood Cup for the best exhibit of any kind in the show, for this group. ELSTREE, JULY 21—Collection of vegetables arranged on a space thirty-three feet by twelve feet. Large Gold Medal and Silver Cup. SHREWSBURY, AUGUST 15—Collection of vegetables arranged on a space thirty-three feet by twelve feet. The President's Trophy, value thirty guineas, awarded for the finest exhibit selected from the non-competitive groups throughout the show. LONDON, OCTOBER 9—Royal Horticultural Society's meeting at the New Horticultural Hall. Collection of vegetables awarded the R.H.S. Gold Medal and the Congratulations of the Council of the R.H.S. This exhibit of vegetables also earned the Lawrence Gold Medal for the best exhibit of any kind staged at any of the Society's Shows during the year 1928. *D. B. C.*

Recalcitrant Gout-weed.—A patch of Gout-weed (Aegopodium) grows in the back lane just outside my garden wall. Year by year it increases, and is always a menace. Various steps have been taken to reduce it; year by year, the blossom is mowed off to prevent seeding. Once I ordered a digging attack; much was dug out and dealt with, but, incidentally, small bits of root were scattered to all points of the compass—result, an increased acreage, perhaps favoured by the cultivation. Having observed that the Mint patch was well nigh exterminated by the few falling droplets of "tar-distillate" winter wash applied to neighbouring Black Currants, this suggested a killing agent; some was watered on at double strength—the grass, the Dandelions, and the Nettles all went black, but the Gout-weed flourished as the proverbial "green Bay Tree." Next, the best part of an hundredweight of agricultural salt was spread over the patch, again the Gout-weed aped the Bay Tree. An experimental fruit tree wash was sent to me for trial; in the advertised dilution it killed even young wood of a Rose, reduced Apple buds to a parlous condition, and did some visible harm to Pear and Quince—evidently a potent agent, but, alas, a strong dilution did not convince the Gout-weed of its "mortal" nature. Next, partly with a view of reducing the nitrogenous content of the soil and so inducing some starvation, bleaching powder was thought of. A pound was dissolved in about a gallon of water; half-a-gallon of this was sprinkled freely on a small area, the can was filled up with water and another patch watered; again, the remaining half-gallon was diluted and a third patch treated. Once more the grass, Nettles, and Docks withered off, but not so the Gout-weed. Another failure was with one of the advertised weed-killers of non-poisonous habit; possibly the more efficient poisonous sorts might have a better effect, but one can hardly scatter such around on a public way. Meanwhile, "Floreat Aegopodium." *H. E. D.*

Black Currant Mite and Lime-sulphur.—Your correspondent, Mr. H. H. Cook (p. 95, February 9) does well to draw attention to the good resulting from spraying Black Currants with lime-sulphur, one in twelve, at the correct period. While at Lydney Park Gardens, I followed up this treatment for several seasons, repeating the spraying when rain washed away the lime-sulphur. In spite of adverse criticism, the bushes were decidedly cleaner and more healthy in every respect as a result of the spraying. *G. H. E., Taplow.*

Asparagus.—Mr. Staward's advice regarding the cultivation of Asparagus is sound, but anyone visiting the Evesham district and observing the method of growing this excellent vegetable in single rows, will find an object lesson in good culture. Most of the growers, and they are legion, sow their own seeds and transplant as and when the natural difficulties of soil permit. They have established a reputation for high-class produce. *G. H. Emmett.*

Partial Soil Sterilisation.—Practical growers have to adapt themselves to the various conditions that arise. Mr. Falconer's method of soil sterilisation is a thoroughly practical one and capable of dealing with quantities of soil, but surely it is better to be prepared with clean soil rather than be up against the loss of a crop of Cucumbers, such as a large grower experienced last year.—*G. H. E.*

VEGETABLE GARDEN.

CULTURE OF BRUSSELS SPROUTS.

I WAS very interested in the article on the Culture of Brussels Sprouts in your issue for February 2 (p. 87). It is still a debated point as to which are most appreciated—large, or medium-sized sprouts. Some few years ago everyone preferred the medium-sized "buttons," and October was usually considered quite early enough to begin picking. Now, I find, the end of August is not too early, and that large sprouts are most in demand. I am enclosing two specimens of each of two varieties which are grown extensively here in the Evesham district. I have been unsuccessful in discovering their names, so will class them as No. 1 and No. 2. No. 1 is an early sort. I have grown it with great success in a private garden, and its "buttons" were much appreciated when cooked. As will be seen, No. 1 has been very severely injured by frost, and in this district there are thousands of this type of Brussels Sprouts spoiling owing to lack of demand and over production. Picking was abandoned, and then frosts, followed by much rain in October, ruined the crops. It is indeed pitiful to see acres of Brussels Sprouts in this condition. The sprouts are the largest I have ever seen, and before being spoilt by frost were as firm as one could wish. No. 2 you will see, is still in prime condition, and will, I am sure, take the place of the early variety in the future. I suggest enough of the No. 1 variety should only be grown for picking from the end of August until October, to be followed by the later sort. No one can be surprised that large sprouts command the best market; they certainly look better in the shops, and there is less waste; they cook a good colour and are of excellent flavour. There has been a great increase in the culture of Brussels Sprouts during recent years. I know of firms who annually devote from twenty to one hundred or more acres to this crop. This season prices have ranged from 10s. per pot of 40 lbs. to 2s. 6d. per pot, but I should put the average at 4s. 6d., at which figure, of course, it is a paying proposition. The culture of Brussels Sprouts is one which requires skill. Good sturdy plants should be planted out three feet apart each way on land which has been well manured, ploughed or deeply dug, and made firm by rolling, especially in the case of light soils. About the middle of June, when the plants are making free growth, a good dressing of nitrate of soda should be given and the soil stirred, but not too deeply, as Brussels Sprouts are surface rooting. About the first week in August the centres of the tops of the plants should be pinched out; this, of course, checks the growth of the plants and encourages the buttons to form and swell more evenly. This method, of course, should not be practised in private gardens, where a continual supply of "buttons" is required from September until March. *James Page.*

[The specimens of Brussels Sprouts which Mr. Page sent us fully confirmed his remarks with regard to their size and firmness; the largest "button" of variety No. 1 measured four-and-a-half inches deep and three-and-a-half inches through, while No. 2 was two-and-a-half inches wide and deep.—Eds.]

RHUBARB.

It has often occurred to me that little use is made of the space under greenhouse stages. The accompanying photograph (Fig. 85) will illustrate one of the many uses to which such valuable space may be put. In these gardens every available foot of room in glasshouses is always occupied, as will be gathered from the illustration, which shows pots on the pathway in which Dwarf Beans are sown; so soon as these are germinated the pots are stood on the stages, and another lot takes their place. While I deprecate the crowding of plants, I am of opinion that the cost of running glasshouses warrants every care being taken to get the most out of them; by forethought and judicious management it is really surprising how successions of plants or crops may follow one another, with the houses always full and paying a handsome profit.

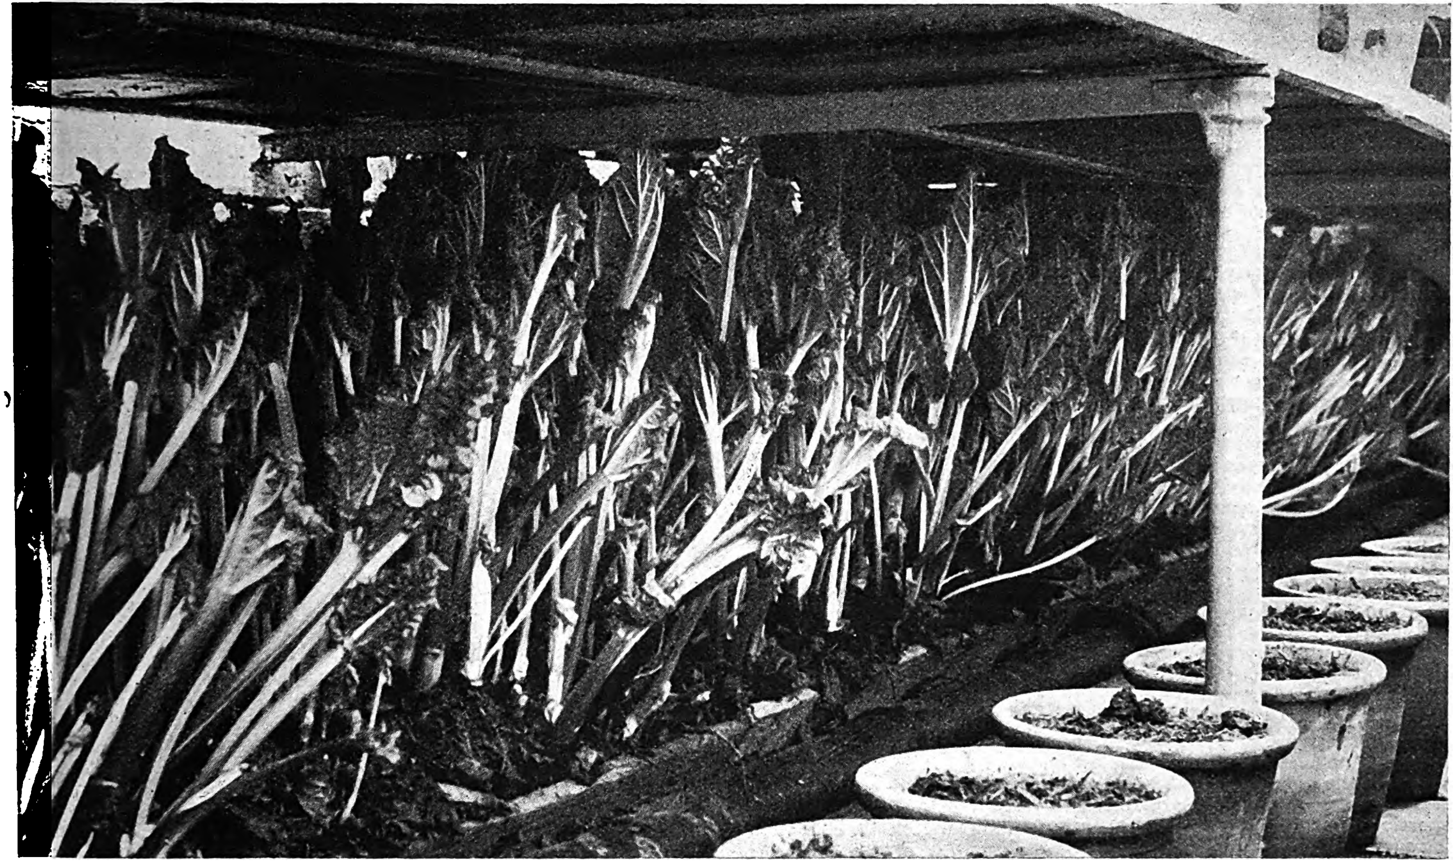

FIG. 85.—RHUBARB UNDER A GREENHOUSE STAGE.

Given available space under stages, Rhubarb may be provided from the end of November until the crop is ready to be pulled outside. This Rhubarb is far superior in quality to that grown in the open, provided no manure is used in the forcing, as this imparts a peculiar flavour which is quite objectionable. Half-decayed leaves, packed well around the roots and well-watered, are all that is necessary to provide the crowns with suitable moisture.

Most garden soils will suit Rhubarb, and during the present month strong roots should be cut up into sets and planted one yard apart each way, in land that has been well prepared. To prevent waste of room, Broad Beans may be sown between the sets at the time of planting and these will in no way interfere with the Rhubarb and the necessary cultivation. While good crowns may be produced in two years, I recommend a three-year system, and as really good crowns are desirable for forcing, no pulling from these crowns should be allowed, or they will be weakened. In my opinion this method of growing Rhubarb to be lifted for forcing is better than covering a patch with pots, boxes, or other material, as the time taken in the recovery of the crowns after they have been weakened, does not compensate for the trouble.

I know of no other crop which is more profitable than Rhubarb for forcing, nor one which will put the ground into better condition; especially is it useful where the dreaded finger-and-toe disease of Brassicas is prevalent, as the three years' rest from such crops usually starves out the disease.

Rhubarb for early forcing must have a period of rest, and this is best secured by lifting the roots in late autumn and exposing them to the elements; the more frost there is, the better.

The varieties Early Albert, Linnaeus, and The Sutton are especially useful for forcing, the last being of such excellent colour and quality that I assume it will be more largely grown when better known. *Allan Falconer, The Gardens, Cheadle Royal Hospital.*

CELERY.

The Celery—Apium graveolens—is a highly prized salad and delicious vegetable, and possesses also considerable medicinal properties, its action being carminative and diuretic. It is also used as a flavouring and tonic in combination with other drugs, such as Coca, Kola, etc., and is recommended as an excellent antidote to rheumatism.

A biennial, native of Europe, including Britain, it is one of our oldest cultivated plants, and its quality depends largely on good cultivation. A light, rich soil is best adapted for its growth, as, although a water-loving plant, it is apt to rot in winter on cold, retentive soils. Like many other biennials, anything in the nature of a check tends to force the plants into premature flowering, therefore, to produce solid stems and hearts it is important that the plants should be kept growing steadily from the germination of the seeds onwards. Too early sowing should thus be avoided, for if it is found impossible to plant the seedlings out when of suitable size, the consequent check at an important stage of growth may result in bolting.

For very early supplies, a small sowing may be made in February, but for the maincrop, early March is soon enough, and this should be made in a warm house or pit. So soon as the seedlings have formed the third leaf they should be pricked off into boxes of light, rich soil, and grown on under moist, warm conditions. When the leaves begin to meet they should be again transplanted, and at this stage no better conditions can be given them than a partially spent hot-bed covered with shallow frames and lights. So soon as established they should receive abundance of air, removing the lights entirely during the day, and finally when the weather is favourable, leaving the plants entirely exposed preparatory to planting out. A later sowing may be made about the middle of April, the seedlings being pricked out in a warm, open border, and finally planted out for late supplies.

The best Celery is generally grown in trenches, and the site having been selected, these should be prepared so early as possible in the spring. They should be heavily manured, and early preparation not only allows the soil and manure to consolidate, but also admits of the ridges being cropped with Lettuce, Spinach, and other quickly-maturing crops. If the trenches are about one foot in depth they will afford some protection to the young plants, and if advantage is taken of a showery day for transferring them with good balls of soil and roots, they will grow away quickly without check. Subsequent culture consists chiefly in keeping the surface soil stirred and free from weeds, the removal of side-shoots, the supply of abundance of water in dry weather and, finally, blanching.

Blanching may be effected by the use of paper bands, but is generally done by earthing, which should be carefully carried out in three stages. The plants should be allowed to grow as freely as possible for some time after planting, and when they have made sufficient growth for earthing to commence, the soil should not be pressed too firmly against the leaves on the first occasion. The object of earthing up is to exclude light, but care should be taken that soil is not forced inside the leaf-stalks; the centres should also be left quite free to allow the heart-leaves to push up and expand naturally, or deformed heads will result. At the final earthing up the soil should be made firm and smooth and sloped each side from the centre, so as to effectually throw off the rain and thus protect the hearts.

The action of alternate frost and thaw soon causes Celery to rot, and it is good practice to protect the ridges in severe weather. Thatched hurdles afford an excellent means of protection and may be removed easily in mild weather, but dry Bracken and long litter laid on the ridges to form a light covering is very frost-resistant and may likewise be used.

Among the enemies of Celery, slugs and snails may be dealt with easily, but great injury is frequently caused by the Celery fly, Acidia heraclei, if prompt steps are not taken to check its ravages. The eggs are laid on the upper sides of the leaves in April and hatch in a few days, when the larvae immediately pierce the tissues of the leaves and feed on their substance. There are several generations during the summer, each brood becoming naturally more numerous than the preceding, if not checked, hence every effort should be made to prevent the first flies from depositing their eggs. Sprinkling soot or lime on the leaves when the dew is on them helps to prevent the fly from depositing its eggs; very light sprayings with paraffin emulsion at intervals of ten days from the beginning of April onwards also act as a deterrent.

A parasitic fungus also attacks Celery and is particularly virulent in some seasons. As a preventive, the plants should be sprayed periodically with a solution of liver of sulphur in the proportion of 1 lb. to forty gallons of water, using a mist-forming sprayer. *W. A.*

GARDEN MANURES FOR MARCH.

All growers are aware that potash is a highly valuable artificial manure which often forms a governing factor in production, and the increasing consumption of potash salts in this country bears testimony to the fact that it can be employed profitably in modern, intensive cultivation. Under an older system of manuring, when farmyard manure was available in abundance, it was often considered that further supplies of potash were not necessary, but it should be borne in mind that the average farmyard manure only contains about 12 lbs. of potash per ton, therefore land that is heavily dressed with farmyard manure does not receive a very large amount of potash from this source.

Under present conditions, it is difficult to obtain adequate supplies of farmyard manure, but the various artificial manures offer a ready means of increasing the quantity of elemental plant food in the soil, and it is doubtful whether the potassic element is always sufficiently considered. Probably one reason for this is that it is generally considered that many soils, and clay soils in particular, contain potash in sufficient quantity for the needs of crops, but while the chemical analysis of soil may show an abundance of potash in a given soil, amounting even to several thousand pounds per acre in the first foot, the application of so small a quantity as one or two hundredweights of potash salts per acre frequently causes a substantial increase in crop. This can only be due to the fact that the potash in the soil in question is in such a state of combination with other soil constituents as to form compounds which will not dissolve in water at a sufficient rate to meet the needs of the plant. The plant can only utilise the potash which enters its substance by the root-hairs, therefore it must first be dissolved by the soil-water, either alone, or assisted by the acid exudation of the roots. Hence, if only a very small proportion of the original potash in a soil is available for the immediate needs of the crop, the application of the same element, in a more or less soluble form, quickly meets these needs.

But it is on the light soils that the lack of potash is generally most marked, and when under conditions of intensive culture for the production of such garden crops as Potatos, Turnips, Beet, Carrots, Onions and Celery, the effect of potash shortage readily shows itself. The effect of potash starvation is frequently seen on such soils, particularly in Potatos, by the yellowing of the margins of the leaves, causing restricted growth and the reduction of the crop to a ver low level, and it not infrequently happens that a mixed fertiliser, offered as a Potato manure, contains too little potash to correct such conditions. In a home-made mixture, the potassic element may be increased at will to meet particular soil conditions, and whereas the generally recommended dressing of 1 cwt. of sulphate of ammonia, 1 cwt. of sulphate of potash and 2 cwts. of superphosphate may give excellent results on a moderately heavy soil, the addition of a further 1 cwt. of sulphate of potash may be necessary to obtain the most satisfactory results on a light soil that is known to be deficient in potash.

Potassic manures increase the formation of starch and sugars, and are, therefore, specially serviceable in the production of high quality Potatos and nutritious roots. They also tend to moderate the rank growth which is favoured in soils of high nitrogen content, and at the same time they neutralise the effect which nitrogenous manures have of delaying the ripening of a crop. Their effect on grass is to benefit the herbage as a whole, but they specially stimulate the Clovers and other Leguminous plants, and should thus be used with moderation on lawns. So far as fruits are concerned, potash is an important element both in the production of sugar and ripening of the crop, and it has been shown that a crop of Apples may be expected to carry away considerably more weight in potash than of phosphoric acid and nitrogen combined. It will thus be seen that an adequate supply of potash to orchard trees which have reached bearing age is of paramount importance; and the need is accentuated in orchards laid down to grass, for thorough tillage as an aid to the liberation of the dormant store of potash in the soil is no longer possible under such conditions, and the deficiency has to be made good.

Kainit is probably the cheapest form of potash, but it should always be applied in the autumn or early winter. It contains a large quantity of common salt and is especially valuable to such crops as Beet, Carrots, Turnips, Asparagus and Brassicas; for Potatos, it is much better to supply sulphate of potash in the spring when preparing the ground for planting. A dressing of 1 cwt. or 1½ cwt. of sulphate or muriate of potash per acre may with advantage be given to such crops as Globe Artichokes, Peas, Beans, Celery and Lettuce, either when sowing or planting, or during the early growing season, while plantations of Currants, Gooseberries and Raspberries, which have not been dressed with kainit, may also be given up to 2 cwts. per acre during the spring. *W. Auton.*

SOCIETIES.

ROYAL HORTICULTURAL.

February 26.—It being the occasion of the Annual General Meeting of the Royal Horticultural Society, this fortnightly meeting was held in the New Horticultural Hall. Considering the bitterly cold weather and snowfall, it was a much better show than might have been expected, and it included a pleasant variety of all possible kinds. Orchids were very well shown; the many plants of Cymbidium and Oncidium were especially effective. The Orchid Committee recommended two First Class Certificates and five Awards of Merit to novelties. It must be quite a long time since the Floral Committee found no novelty worthy of distinction, but on the present occasion neither section recommended an award. There were six novelties of fair merit before Section B, but only a nondescript greenhouse Cyclamen was submitted to Section A, and this was promptly and rightly rejected. The chief floral features in the hall were forced shrubs, alpines, Carnations, Roses and stove plants The exhibits of fruits and vegetables were more imposing than usual at this time of the year. The central collection of vegetables arranged so skilfully by Messrs. Sutton and Sons was exceedingly valuable, as also was the collection of Potatos from Messrs. Dobbie and Co., while the dishes of Apples illustrated the best sorts for late use. There were the usual pleasant paintings of garden scenes and flowers, and the beautiful transparencies by Messrs. Malby and Co. included several for use in *The Gardeners' Chronicle*.

Orchid Committee.

***Present*:** Mr. Frederick J. Hanbury (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. Lionel de Rothschild, Mr. Stuart H. Low, Mr. John C. Cowan, Mr. T. W. Taylor, Mr. Fred. K. Sander, Mr. A. A. McBean, Mr. Charles H. Curtis, Mr. H. G. Alexander, Mr. Arthur Dye and Colonel Stephenson Clarke.

First Class Certificates.

Cymbidium Letty, Wyld Court var. (*C. Merlin* × *C. Gottianum*).—This has flowers of large size and wonderful substance, borne on an erect spike. The flowers are white with a suspicion of blush. The lip is blush with dark purple-brown markings and a yellow central line. Shown by Sir William Cooke, Bart. (gr. Mr. H. Butcher), Wylde Court, Hampstead-Norris, Newbury.

Laelio-Cattleya Sunbelle, Brockhurst var. (*L.-C. Serbia* × *C. Thora*).—A very fine hybrid with large blooms of fine form and colour. The wide, fringed petals are rosy-mauve, the sepals a trifle darker. The wide lip has a large, dull yellow area, with pinkish-mauve side lobes and a frilled, purplish-mauve apex. Shown by F. J. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead.

Awards of Merit.

Cattleya Remy Chollet var. President (*C. Monarch* × *C. Trianae*).—This has large flowers, of which the plant bore two on one stem. The sepals and petals are soft mauve, the base of the lip is also mauve, but the broad apex is deep Tyrian-purple, with a mauve margin. The throat is deep yellow. Shown by Messrs. Sanders.

Cymbidium Morvyth, Exbury variety (*C. Redstart* × *C. Alexanderi*).—In this charming hybrid the flowers are of a lovely, soft rose-pink colouring with darker veins and shading. The lip has a horse-shoe-shaped, deep red mark on the apex. Shown by Lionel de Rothschild. Esq. (gr. Mr. B. Hills), Exbury, Southampton.

Odontioda Acis var. Radiant (*O. Royal Gem* × *O. Orion*).—A handsome and richly coloured hybrid with flowers of large size and good form. The sepals and petals are deep cardinal crimson, while the lip has a purplish apex and a golden crest. Shown by Messrs. Charlesworth and Co.

Odontoglossum Harold var. Distinction (*O. eximium* × *O. Jasper*).—A bright and distinct hybrid, with shapely flowers of rich, deep red colour, with fleckings of white, and a white, golden crested lip. Shown by Messrs. J. and A. McBEAN.

Cymbidium Rosanna (*C. Kittiwake* × *C. Alexanderi*).—Flowers of fine substance, milky-white and blush-tinted, some of the sepals having a pink line. Lip blush-pink, with numerous bright rose-purple dots at the apex. Shown by Messrs. H. G. ALEXANDER, LTD.

GROUPS.

Cymbidiums and the golden-lipped Oncidium splendidum were prominent features in the large group arranged by Messrs. SANDERS. Varieties of Cymbidium Vesta and C. Venus were particularly good, and there was a grand spike of C. President Wilson. Aerides cylindricum, the rare Aerido-Vanda Mundyi, Masdevallia civilis, Coelogyne graminifolia, Trias picta and Bulbophyllum mundulum were interesting Orchids associated with the bolder Phalaenopsis Schilleriana, Cattleya Tityus, C. Monarch, C. Remy Chollet, Brasso-Laelio-Cattleya Pink Pearl var. Sunrise and the brilliant Laelio-Cattleya Hypolita.

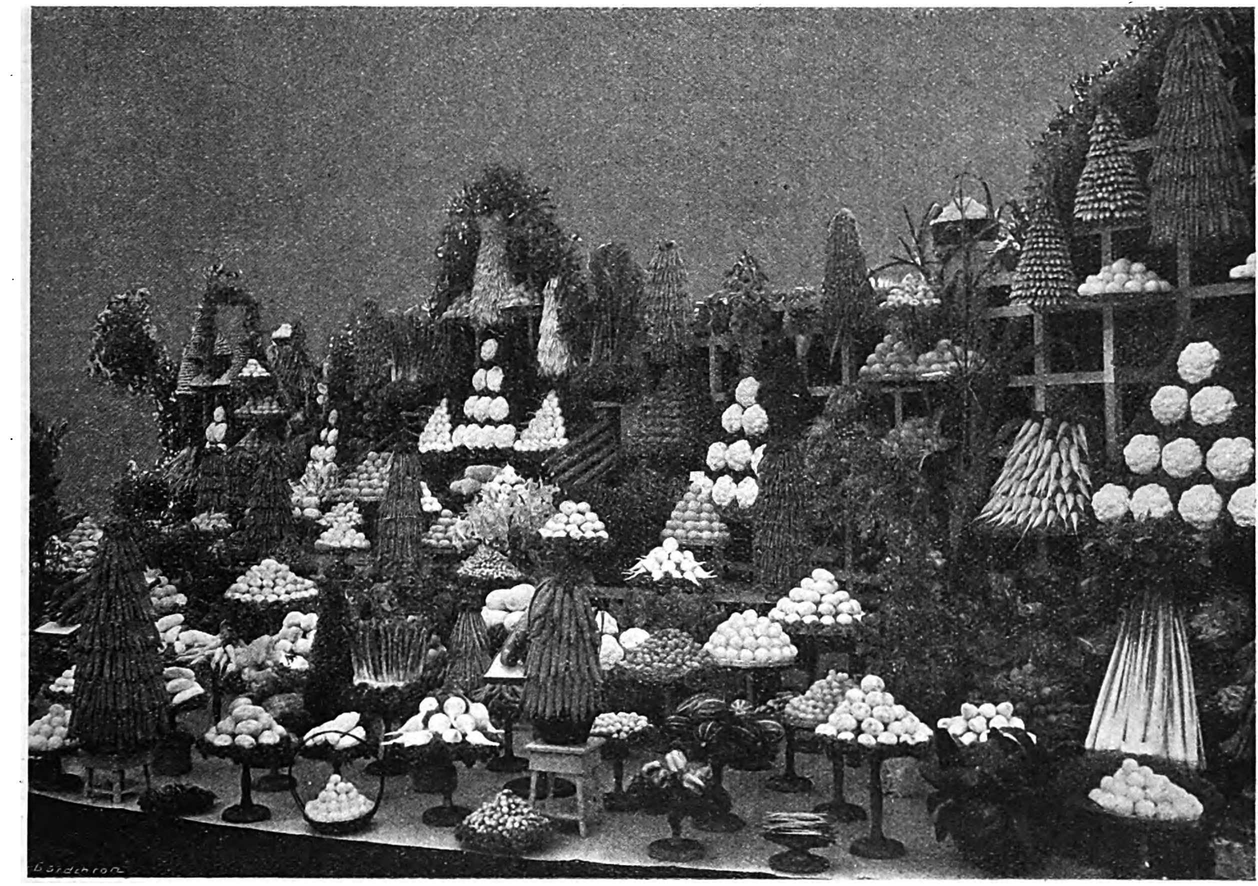

FIG. 86.—VEGETABLES EXHIBITED BY THE HON. VICARY GIBBS, V.M.H. (GR. MR. E. BECKETT, V.M.H.), AT CHELSEA SHOW, 1928. (see p. 166).

Messrs. H. G. ALEXANDER, LTD., contributed a group of finely-grown plants in which were two beautiful examples of Coelogyne Mooreana, Westonbirt variety, each carrying a pair of spikes of lovely white and yellow flowers. Other fine plants were of Cymbidium Lady Bird, C. Butterfly, C. Ruff, C. Mavis, Cypripedium Noel Hardy, C. Gnome, C. Lord Wolmer and C. Virgil, the last-named carrying three very attractive flowers.

Cymbidiums in great variety were shown by Messrs. J. AND A. McBEAN, a few of the more important sorts being C. Albania, C. Alexanderi, C. Swallow, C. Coningsbyanum and C. Pearl. Along the front of the group were charming plants of the little Oncidium cheirophorum, Epiphronitis Veitchii, and various Cypripediums, while in the body of the exhibit we noted good examples of Odontoglossum Rosina, O. Conqueror, O. Red Admiral, O. Phoebe, O. xanthinum, Laelio-Cattleya Hassellii var. alba, and the beautiful Cattleya Enid var. alba.

Messrs. COWAN AND Co. had a well arranged and pleasingly-furnished group, the Ferns and moss enhancing the beauty of the Orchids. Cymbidium Erica, C. Estelle and C. Coningsbyanum, and Oncidium splendidum, provided a good background for Brasso-Cattleya Apollo, Cattleya Clotho, Brasso-Laelio-Cattleya Hilary, several pretty Odontoglossums, Odontioda Metis, Cypripedium Alcibiades var. Illustris, C. Tom Worsley, C. Caractacus and C. Commodore.

A large group in which Odontoglossums were the leading feature, was arranged by Messrs. CHARLESWORTH AND Co. Among the many good things displayed we were especially attracted by Odontoglossum crispum, O. c. xanthotes, O. dalmatica, O. Omega, O. Toreador, O. Clydonia, and O. Blue Peter; and Odontioda Acis—very fine. Other attractive and interesting subjects were the rare Acacalli scynanea, with two flowers; Sophronitis grandiflora in fine form and colour; Oncidium Papilio, Odontonia Duchess of York and Potinara Juliettae var. Sultan.

Dendrobium chessingtonense and Laelio-Cattleya Penshurst, with their soft yellow colouring, were very attractive in the group shown by Messrs. STUART LOW AND Co. The display included Sophro-Cattleya Sistron, Lycaste Balliae, Laelio-Cattleya Eunice—of L. anceps parentage; the charming Odontoglossum Jeanette, betraying its descent from O. Rossii; O. Insleayi, Odontioda Queen Mary, Cattleya Tityus, Dendrobium Austinii, and the quaint old Pleurothallis Roezlii.

Mr. J. EVANS had a small group of Cymbidiums and Cypripediums, the latter including C. Memoria John Walker, C. Alcibiades var. Illustris, and C. Christopher var. Grand Duke Nicholas; Odontioda Queen Mary var. Radiant was also well shown in this group.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. F. McLeod, Mr. R. B. Long, Mrs. Ethel M. Wightman, Mr. Arthur Turner, Mr. M. C. Allwood, Mr. J. M. Bridgeford, Mr. Donald Allan, Mr. W. B. Gingell, Mr. C. F. Langdon, Mr. R. Findlay, Mr. A. E. Vasey, Mr. James B. Riding, Mr. Charles E. Pearson, Mr. G. W. Leak, Mrs. Helen Lindsay Smith, Mr. Courtney Page, Mr. E. R. Janes and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Gerald W. E. Loder (in the chair), Mr. W. J. Bean, Mr. G. Reuthe, Mr. A. Bedford, Mr. T. Hay, Mr. Reginald Cory, Mr. W. B. Cranfield, Mr. F. G. Preston, Mr. Mark Fenwick, Mr. L. R. Russell, Mr. E. H. Wilding, Lady Beatrix Stanley, Mr. E. A. Bowles, Mr. G. Yeld, Mr. R. C. Notcutt, Sir William Lawrence, Bart., Mr. Hiatt C. Baker, Mr. Clarence Elliott, Mr. Charles T. Musgrave and Mr. N. K. Gould, Secretary.

GROUPS.

While the individual specimens of the trees and shrubs were not quite so large as at the two earlier shows, their increased floriferousness made them particularly attractive. Facing the entrance, Messrs. W. CUTBUSH AND SON arranged a very showy exhibit of Azaleas planted in a boldly disposed rock garden. The Azaleas included heavily-flowered bushes of the mollis and the rustica varieties. They also had good examples of Pieris polifolia and Prunus triloba fl. pl.

A number of interesting Chinese shrubs were associated with other sorts by Messrs. HILLIER AND SONS. In the centre of their group they had graceful Bamboos, and also showed good examples of Berberis japonica var. Bealei and Corylopsis pauciflora. Well-flowered bushes of Staphylea colchica, Erica lusitanica and other shrubs formed a good background to breadths of Primula Barrowby Gem, P. Wanda, P

Winteri and other early border flowers in the group of Messrs. J. Cheal and Sons. A particularly good specimen of Forsythia spectabilis occupied the centre of an attractive group arranged by Messrs. Waterer, Sons and Crisp, who also showed Rhododendron praecox, Muscari azureus, Anemone blanda rosea, Iris reticulata and other flowers. Spiraea Thunbergii and Prunus triloba fl. pl. were well shown by Messrs. Wm. Wood and Son, who used them as a background to batches of Anemone blanda rosea and such Saxifrages as S. Burseriana Cookside and S. b. tridentata. Messrs. Patricks again showed a good selection of dwarf Conifers suitable for the rock garden, and included well-flowered Ericas in variety.

As a background to a very showy planting of spring bulbs, Messrs. D. Stewart and Son placed Azalea Yedogawa, A. Hinodegiri and A. Betty. Their early Narcissi included N. Queen of Spain, N. triandrus albus and N. Orange Cup. Tulipa Kaufmanniana, Iris reticulata and Snowdrops were also freely shown. A low rock garden exhibit by Mr. K. Therkildsen was planted with Ericas, Primula Wanda and Saxifrages.

The end space of one of the tables was well filled by Messrs. Barr and Sons with a very spring-like grouping. Their early Narcissi included N. W. P. Milner, N. nanus, a good N. minor seedling, and a broad planting of N. Queen of Spain. The valuable, dwarf, early Irises were an important feature of this attractive exhibit, and these included the following varieties:—Princess, pumila alba, Seraphin, Naomi, Socrates and Cervantes. The Lye Green Nursery Co. had a neat rock garden exhibit planted with Ericas, erect little Conifers and Saxifrages.

An especially successful alpine exhibit was arranged by Messrs. M. Prichard and Son. The bold breadths of Saxifraga His Majesty, S. Mrs. G. Prichard and S. Riverslea were particularly attractive, while the bonny examples of Magnolia stellata and the patches of Anemone blanda rosea and Anemone fulgens added to the value of the exhibit. The Misses Hopkins had a small rock garden where they displayed Blue Primroses and early flowers.

Many well-coloured Codiaeums (Crotons) of useful size were used by Messrs. L. R. Russell, Ltd., in their attractive group of stove plants. They also displayed Dracaena Sanderi, D. Bausei, the old favourite Euphorbia jacquiniaeflora, Pandanus Veitchii and several Bromeliads. Mr. George Prince showed, in lovely branches of Fortune's Yellow and the Yellow Banksian, the first Roses of the year. The Misses Allen-Brown brought particularly good bunches of Princess of Wales Violets.

Several large bushes of Camellias and Mimosas (Acacias), with dwarfer plants of Ericas and Epacrises, were staged by Messrs. Stuart Low and Co. next to their Carnations, which latter included Thomas Ives, Topsy, Mrs. Ives, Eileen Low and Countess of Harewood. In their good collection of Carnations, Messrs. C. Engelmann, Ltd., included vases of the vividly coloured Spectrum, Mrs. A. J. Cobb and Topsy, and the bright pink Betty Lou and Mab. The rich yellow Wivelsfield Buttercup and Maine Sunshine were prominent in the collection of Messrs. Allwood Bros., who also showed the bright orange Maud Allwood, with many other varieties.

On the dais were set out the new plants and these included Leucocoryne ixioides odorata, the fragrant blue and white Liliaceous plant collected by Mr. Clarence Elliott in Chile last year and now shown by Lionel de Rothschild, Esq., Exbury, Hampshire; and Fritillaria karadaghensis, a species from N. Persia shown by Messrs. Wallace and Co., and presented to the Royal Gardens, Kew. It is an uncommon little species. The stems are about nine inches in height and furnished with alternate, glaucous leaves. The rounded flowers are of reddish-bronze colour on the outsides and spotted with crimson, with yellow apices in the interior. Rhodothamnus Solanderi, shown by Sir William Lawrence, Bart., is a bushy little New Zealand shrub bearing ovate, deeply serrate leaves and orange-coloured, tubular flowers. R. Barclay Fox, Esq. (gr. Mr. S. Smith), Penjerrick, Falmouth, staged good trusses of Rhododendron Liliani and sprays of Pieris japonica and Laurelia errata.

There was a large array of paintings at this meeting, among the numerous exhibitors being Miss Alice F. Wilkinson, Mrs. Henry Spencer, Miss Marion Broom, Miss E. Frances Drake, Miss Edith A. Andrews and Miss Winifred Walker. There were also several exhibits of garden designs, notably those of Messrs. Bakers, and Mr. Percy S. Cane, but the most interesting exhibit in the art section was undoubtedly that staged by Messrs. Reginald A. Malby and Co. This exhibit comprised a magnificent collection of photographic reproductions of gardens and flowers, together with many exquisite colour transparencies, and series of lantern slides, beautifully and naturally coloured and suitable for illustrating lectures on such subjects as alpine flowers, vegetables, fruits, English gardens, etc. The transparencies of the coloured plates which have appeared recently in *The Gardeners' Chronicle* attracted considerable attention, and assisted in making this exhibit one of extreme interest.

Narcissus and Tulip Committee.

Present: Mr. G. W. Leak (in the chair), Mr. W. Poupart, Maj. G. Churcher, Mr. Jan de Graaff, Mr. Peter R. Barr, Sir Daniel Hall, Miss E. Willmott, Mr. C. W. Needham, Mr. F. A. Secrett, Mr. Charles H. Curtis, Mr. W. B. Cranfield and Mr. A. Simmonds, Secretary.

There were no exhibits of novelties before the Committee at this meeting.

Group.

An attractive mixed collection of Tulips, Narcissi and Roman Hyacinths, growing in ornamental bowls, was set up by Messrs. R. H. Bath, Ltd. The Narcissi included such charming sorts as Brilliancy, Sunrise, Flame, and Orange Cup; among the trumpet Daffodils were The President, Golden Spur, King Alfred, Henry Irving and several unnamed seedlings. Tulips were represented by good examples of Vermilion Brilliant, Golden Queen, Mon. Tresor and Van der Neer, and Hyacinths by the varieties Grand Maitre, L'Innocence, Lady Derby, pink, and La Grandesse.

Fruit and Vegetable Committee.

Present: Mr. Jos. Cheal (in the chair), Mr. E. A. Bunyard, Mr. W. Poupart, Mr. E. Neal, Mr. W. F. Giles, Mr. Edwin Beckett, Mr. J. Basham, Mr. W. H. Divers, Mr. G. F. Tinley, Mr. P. D. Tuckett, Mr. J. Wilson and Mr. F. Jordan.

There were no novelties before this Committee.

Groups.

Occupying the centre position in the hall was a circular group of excellent vegetables and salads, staged by Messrs. Sutton and Sons. The exhibit was, as might be expected, arranged tastefully, while the quality of the produce shown, considering the inclement weather experienced of late, can only be described as magnificent. Potatos were represented by perfect tubers of many varieties, notably Golden Wonder, Red King, The Bishop, Express, Mr. Breese, Arran Comrade and Catriona, while the varieties of Broccoli staged were Sutton's Winter Mammoth, Early Roscoff and Superb Early White. There were Carrots, both long- and stump-rooted, in several varieties; Leeks, Parsnips—the roots of the variety Tender and True and Sutton's Student being exceptionally good; Onions, in such varieties as Selected Ailsa Craig, Sutton's A.1., Veitch's Main Crop, Sutton's Long Keeping, Brown Globe and Reading; and Beetroots, Seakale, Turnips, Brussels Sprouts, Celery, dwarf French Beans and Jerusalem Artichokes, most of them in several varieties. Witloof Chicory was well shown, and there were excellent baskets of Mustard and Cress, while other salads included Salad Potatos, Radishes in several types, Batavian Endive, Stachys tuberifera and Cabbage Lettuce. Ornamental Gourds, Asparagus, Rhubarb, Mushrooms and Fennel were also included in this grand exhibit.

Potatos in many sorts were staged by Messrs. Dobbie and Co., Ltd. Among early varieties were Witch Hill, Di Vernon, Mr. Breese and The Cardinal; early maincrop varieties were represented by King Edward, The Ally, Majestic, Arran Consul, Doon Star, Catriona, Great Scot and others; and maincrop Potatos by Golden Wonder, Field-Marshal, Incomer, Mauve Queen and Kerr's Pink. The Bishop was shown as a late variety.

Apples were exhibited, in about fifteen varieties, by Messrs. George Bunyard and Co. Ltd. The fruits were in excellent condition, among the sorts which made special appeal being Newton Wonder, Bramley's Seedling, Lord Hindlip, Claygate Pearmain, Allen's Everlasting, Upton Pyne, Orleans Reinette, Cox's Orange Pippin, Belle de Boskoop and Sanspareil.

Messrs. T. Rivers and Son, Ltd., were represented by a splendid collection of Citruses, the majority of the specimen trees shown being heavily laden with fruits. There was a grand tree of the St. Michael's Egg Orange in the centre of the exhibit, other Oranges represented being Mrs. Markham, Long Orange, Bittencourt, Nonpareil, and Thomson's Improved Navel. There were also well-fruited specimens of Citrus corniculata, the Myrtle-leaved Orange, Citrus medica, Bijou Lemon, Imperial Lemon and the Variegated Orange.

Annual Meeting.

The Annual Meeting of the Fellows of this Society was held in the Lecture Room of the New Hall, at 3 p.m. There was a good attendance, some two hundred Fellows being present, presided over by Mr. G. W. E. Loder, the President of the Society.

Following upon the reading of the notice convening the meeting, the Chairman expressed the thankfulness of all the members of the Society on the progress made by His Majesty, The King, in his recovery from a long and severe illness, and spoke of their appreciation of the Queen's care and devotion to His Majesty throughout. He then moved the proposal that the regret and deep sorrow of the Fellows, in the death of their late President, Lord Lambourne, be placed on record, and that their sincere sympathy be tendered to Mr. Robert Lockwood and other members of his family. This was passed in silence, the Fellows standing.

The minutes of the last Annual Meeting were passed, and Mr. Loder then reviewed the Report of the Council for the past year. He specially emphasised the fact that the cost of building the New Hall had been met by the funds of the Society, and also laid stress upon the necessity of repairing and partly reconstructing the old hall, with a view to enlarging the accommodation for the office staff and library. He pointed out that since 1904, to the present time, the number of Fellows had increased from 8,500 Fellows to 26,500, and that, consequently, the work of administration had increased enormously and had outgrown its present accommodation. Several schemes have been put forward to deal with this pressing need, the proposal favoured being that of building an additional floor for the library and converting the present library into offices, and to reconstruct the basement on modern lines. The total cost of this work is estimated at from £16,000 to £17,000.

Mr. Musgrave, The Treasurer, in presenting the Statement of Accounts, pointed out that the financial position of the Society was quite sound and very satisfactory. He hoped that, in a few years, the reserve fund, which had been used to meet the cost of the New Hall, would again be instituted. The Report and Statement of Accounts were adopted without comment.

The next business before the meeting was the election of a President. Mr. Musgrave proposed that Mr. G. W. E. Loder, who was appointed President of the Society on the death of Lord Lambourne, by the Council, be elected, a proposal which met with the hearty approval of all the members present. Mr. Loder thanked the members for the honour thus conferred upon him, and promised them his whole-hearted interest in the welfare of the Society. He then proposed that Mr. Musgrave be re-elected Treasurer; this was carried unanimously. Mr. E. A. Bunyard, Dr. A. W. Hill, and the Hon. H. D.

McLaren were elected to the Council; the numerous Vice-Presidents were re-elected *en bloc*, and Mr. A. C. Harper was appointed Auditor.

Following upon the election of officers, the presentation of the various cups and medals won during the past year was made by Mr. Loder.

The meeting terminated with a vote of thanks to the President, proposed by Mr. F. J. Hanbury, seconded by Mr. Jos. Cheal, and supported by Mr. R. W. Wallace, who stated that the Society was extremely fortunate in securing Mr. G. W. E. Loder as its President, a statement heartily endorsed by all the Fellows present.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

MR. ISAAC FLEMING, Curator of Parks, Paisley, presided over a largely attended meeting of members on Wednesday, Feb. 13, when Mr. Hugh MacSkimming, Auchenault Gardens, Edinburgh, delivered a lecture on "Late-flowering Chrysanthemums."

In regard to the propagation of new stocks, he said that for the greater bulk of late varieties it was best to have the cuttings rooted in the early part of the year, but those which had to be stopped in March required to have the cuttings taken so early as possible, because it was a bad practice to root a cutting in February or March and then stop it. To maintain the vitality of the stock, cuttings should only be taken from plants that had shown satisfactory growth and had produced good flowers, for no amount of good cultivation could make up for inherited weakness. Only root cuttings should be taken, and these should not exceed three inches in length. By planting an inch deep and thereby keeping the base of the cutting near the surface, quicker rooting was obtained.

After discussing composts and the work of potting on, the lecturer dealt at some length with the subject of manures. Bone-meal, he considered to be the most over-rated fertiliser on the market, and it was absolutely of no use for annual or pot plants that had to make their growth in a month or two. He began the feeding of his plants when they were in three-inch pots and continued the treatment during the growing season. To build up the frame of the plant, he prescribed a solution of sulphate of potash, one part, and soot three parts, applied two or three times a week. Sulphate of ammonia and nitrate of soda were excluded from the treatment. Potash was more expensive, but a little went a long way, and it was cheaper in the end. When the plants were in six-inch pots, an eye should be kept on their growth, and if the leaves were found to be closing together, it was advisable to apply a little nitrogen, which should be stopped whenever the buds appeared and there was sufficient of that element in the soil. If the plants are not heading, give them a little phosphate of potash, which acts like magic. Sometime in August the plants should be top-dressed, and by September 25, or earlier, according to the weather, they would require to be housed. His advice was, never feed Chrysanthemums after the leaves are fully developed. Over-feeding caused damping and distortion of the blooms. At Auchenault, six hundred large blooms are grown annually, but not a single petal was lost through damping, a testimony to the treatment of feeding the plants well in infancy and during the growing stages, but not when indoors.

The syringing of Chrysanthemums under glass should only be done in the early part of the year, and for the first week or two after they are housed in the autumn, should the weather be at all bright. At the latter period, the plants should receive all the ventilation possible, and immediately the buds begin to show colour syringing should be discontinued and temperature of 50° to 55° maintained to open the flowers.

Mr. MacSkimming afterwards explained the operation known as "taking the bud" by the aid of lantern illustrations, and at the close he was accorded a vote of thanks on the motion of Mr. Joseph Dobson.

READING GARDENERS'.

THE fortnightly meeting of this Association was held in the Abbey Hall, on February 4, when Mr. W. Broomfield presided over a large attendance of members.

The lecture for the evening was entitled, "The Best Hardy Plants of Recent Introduction, and the Best of the Older Hardy Plants," the lecturer being Mr. Thomas Carlile, of Lodden Nurseries, Twyford. He gave quite an educational review of the best hardy plants and the conditions most congenial to them; he pointed out that the gardener must discover, by his own experience or observation, the plants which are suited to his own particular district. The many families dealt with were numerous, those strongly recommended being Michaelmas Daisies, Campanulas, Chrysanthemum maximum, Delphiniums, Gaillardias, Heleniums, Lupins, Phloxes, Rudbeckias, Salvias, Scabious and Veronicas. An interesting discussion followed, at the close of which the lecturer received a hearty vote of thanks.

In the class for three dishes of Apples, three distinct varieties, there were six good entries and, notwithstanding the lateness of the season, some very fine fruits were shown. The first prize was awarded to Mr. A. H. Dow, The Gardens, Sulhamstead House; second, Mr. W. BROOMFIELD, The Gardens, Cliffe House, Mapledurham, and third, Mr. M. GODDARD, The Gardens, Bear Wood. In the class for single-handed gardeners, there was only one entry, Mr. A. W. EGGLETON, Redlands Road, Reading, being awarded the second prize.

In the non-competitive section, a remarkably fine collection of Apples, in fact, the finest that has been staged at these meetings, was shown by the authorities of the Reading University, represented by Mr. A. J. COBB, Head of the Horticultural Department. It consisted of no less than thirty-five distinct varieties, all of good colour and in splendid condition. It was awarded a First Class Certificate. Mr. C. J. HOWLETT, The Yews, Earley, showed seven dishes of Apples in distinct varieties.

THE next meeting of this Association was held in the Abbey Hall on February 18, and, notwithstanding the inclement weather, there was an excellent attendance. Mr. W. Broomfield presided.

A lecture entitled "The Propagation and Raising of Fruit Trees," was given by Mr. W. Martin, of Victoria Nurseries, Oxford Road, Reading. In his opening remarks, he stated that the subject he had selected was, to him, one of the most interesting branches in horticulture, and he would speak of his own practical experience, over many years, in this particular work. He described the various stocks and their uses, commencing with those for Apple, and illustrated by examples the methods and principles of grafting. Similar explanations were given with regard to Pears, Plums, Cherries, Peaches, Nectarines and Apricots. It was an extremely interesting lecture, full of valuable information to everyone interested in the subject, and it was followed by an animated discussion.

In the class for six spathes of Arum Lilies (Richardias) there were only two entries, the first prize going to Mr. A. MANLEY, The Gardens, Highfield, Heckfield; and the second to Mr. F. G. RABBETTS, The Gardens, Bulmersche, Earley.

In the non-competitive section, Mr. A. WEBB, School Road, Tilehurst, staged several dishes of Apples, the specimen fruits of Bramley's Seedling, Annie Elizabeth, Newton Wonder and Cox's Orange Pippin being of good colour and excellent condition for so late in the season.

MORAY AND NAIRN FORESTERS.

THE monthly meeting of the members of this Society was held in Elgin, the leading feature being a delightful address by Mr. F. Machray, forester, Dunphail, Morayshire, on contrasts in the various methods of forestry adopted in England and Scotland. To those of his listeners who have never had English forestry experience, the address proved highly interesting as Mr. Machray has a wide experience of forestry in the midlands and south of England, and is well acquainted with Scottish methods of forestry. Dealing chiefly with the hardwoods grown in the midlands and south of England, Mr. Machray lamented how the advance of forestry in these areas was retarded through game preservation, fox-hunting, etc., handicaps quite foreign to the Scottish forester.

A keen discussion followed the address, and on the proposal of Mr. A. Morrison, forester, Brodie, Mr. Machray was warmly thanked for his interesting lecture.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

MR. T. R. BUTLER presided at the monthly meeting of this Society, held at the R.H.S. Hall, on Monday, February 11. Thirteen new members were elected.

Two members over the age of seventy years withdrew the sum of £117 7s. 8d. from their deposit accounts, and the sum of £158 18s. 4d. was passed for payment to the nominees of three deceased members. The sick pay for the month on the Ordinary side came to £137 9s. 5d., and on the State section to £102 8s. 2d.; maternity claims were £10 0s. 0d. The sum of £31 7s. 3d. was granted to eight members for dental and optical treatment, and fifteen other cases were considered.

The draft of the annual report was submitted and approved for the annual meeting on March 11.

LANARKSHIRE FRUIT GROWERS'.

MR. FORREST presided at the annual meeting of this Society, held in Glasgow. The Secretary detailed the work undertaken by the Committee during the past year. The question of railway freights and the checking of weights had been discussed with representatives of the railway company, and the matter was remitted back to the Committee for further consideration and adjustment. Reference was made to the part taken by members of the Association in connection with recent prosecutions under the Merchandise Marks Act, and satisfaction was expressed at the results achieved.

The following office-bearers were elected for 1929:—President, Mr. Forrest, Holehouse, Hazelbank; Vice-President, Mr. James Gilchrist, The Pleasance, Kirkfieldbank; and Secretary and Treasurer, Mr. John Lightbody, Lanark. The retiring members of Committee, Messrs. Alex. Prentice, Brookbank, Carluke, and William Graham, Byrewood, Hazelbank, were re-elected, and Mr. James Wison, Westport, Lanark, was appointed to the vacancy caused by the retirement of Mr. Minehead.

Obituary.

John Frisby.—The funeral took place at Ruskington, near Sleaford, on Friday, February 22, of Mr. John Frisby, who died during the previous week, at the age of eighty-seven. He had lived at Ruskington in retirement for twenty-six years, but led an active life, pursuing his hobby of horticulture, and his garden was the admiration of all passers-by. Mr. Frisby was the son of the late Mr. Charles Frisby, head gardener to Lord Chaplin, at Blankney Hall, where he gained his first experience in horticulture. After spending some time at Messrs. Veitch's well-known nurseries, he was appointed, while still in his early twenties, gardener at Hainton Hall, North Lincolnshire. Years ago, both Mr. Frisby and his father enjoyed a great reputation as judges at flower shows.

S. Segar.—We regret to announce the death of Mr. Samuel Segar, of Messrs. Wills and Segar South Kensington. For very many years Mr. Segar had been one of the leading London florists; he was highly esteemed and greatly liked.

THE LATEST TRADE MARKS.

THIS list of Trade Marks, of interest to readers, has been selected from the Official *Trade Marks Journal,* and is published by permission of the Controller of H.M. Stationery Office.

MORKAM.

495,834.—Illustration of a shield device and two Roses, a yacht and the word MORKAM. Cutlery and edge tools, all made at Morecambe. Souplex, Limited, 36, Claremont Road, Morecambe. January 16.

SEMESAN.

491,437.—Fungicides and seed disinfectants, all being goods in Class 2.—E. I. Du Pont De Nemours and Co., 1,007, Market Street, Wilmington, State of Delaware, United States of America. January 16.

SPRAKAR.

497,455.—Chemical substances used for agricultural and horticultural purposes.—John Gadd (Colour and Chemical Agencies), Limited, 126, Bishopsgate, London, E.C.2. January 9.

CLAUDEN.

496,931.—Chemical substances used for agricultural and horticultural purposes.—August Karreth, trading as Luitpold Werk Chimischpharmazuetische Fabrik (Luitpold-Werk), Zielstattstrasse 9, Munchen 25, Bavaria, Germany. January 2.

ANSWERS TO CORRESPONDENTS.

CREOSOTE FUMES AND "SCALDED" FOLIAGE.—*G. R. N.* The leaves of your Arums, Freesias and Potatos are suffering from "scald" following the use of creosote on the pipes of the house in which they were growing. The Potato foliage is free from any fungus organism. The Arum foliage bears hyphae of a saprophytic fungus only, while a few of the Freesia leaves show signs of mottling due to some organism at present unknown (vide *The Gardeners' Chronicle,* January 12, 1929, p. 37).

DEVONSHIRE APPLES.—*J. C.* The three Apples you mention, *i.e.*, Hermann's Pippin, Devonshire Queen and Hollow Core, as growing in Devonshire, are quite genuine varieties, although not grown very extensively at the present day. Hermann's Pippin has fruits of medium size, of round and irregular form, with a yellow skin tinged with green on the shaded side, and striped and mottled with dark crimson on the side exposed to the sun. The flesh is yellowish-white, tender and juicy. It is a Somerset Apple, of only ordinary quality and only suitable for cooking purposes, being in season from October to January. Devonshire Queen has medium-sized fruits, round and irregular in shape, bright yellow, striped and flushed scarlet. It is a culinary sort, in season during October. It is of inferior quality and hardly worthy of cultivation. It originated in Devonshire, and was known so long ago as 1820. Hollow Core has conical, irregular and ribbed fruits of medium size; they are smooth and shiny, pale green on the shaded side, flushed with pale red on the side exposed to the sun. This Apple is described as an excellent culinary sort, with a fine perfume; ripe in September. It is stated to be grown extensively in Berkshire, and was at one time popular for market purposes.

LARKSPURS FAILING.—*B. N.* The Larkspur plants appear to have been attacked by a species of fungus causing "foot rot" but only secondary agents (Sciara larvae and mites belonging to the Tyroglyphidae) were present in the diseased portions. The affected plants should be removed and burnt, and the soil subjected to sterilisation before it is used again.

REMARKS.—Owing to the milder weather conditions the supplies from home-growers have shown some increase during the past week, notably Daffodils, Tulips, Narcissus ornatus and Carnations. A good selection of Tulips is now on sale, including more double varieties and some very fine Darwins. Small consignments of Narcissi from the Channel Islands, consisting of Grand Primo and White Pearl, have realised high prices owing to fewer French Paper White Narcissi being available. Few French blooms are expected this season owing to severe weather conditions. Liliums still realise high prices owing to short supplies; this also applies to single Violets, Freesias and Roses. Lily-of-the-Valley continues fairly plentiful and good in quality. All foliage is exceptionally scarce at the present time and insufficient to meet present requirements.

Fruit: Average Wholesale Prices.

REMARKS.—Most sections of the market are feeling the absence of demand that usually accompanies severely cold weather. The department most materially affected is undoubtedly that handling Cape fruits. Quantities are heavy, but the Peaches, Pears, Plums and Grapes are meeting a demand that is anything but satisfactory. Hothouse Grapes are selling particularly well, probably due to some extent to the amount of illness which persists in the country, as well as to a shortage of supplies from Belgium. Apples from the North American continent, although in comparatively small supply, are quoted easier. Some really good English Bramley's Seedling from various cold stores are now available and selling quite well at a figure the producers will no doubt consider satisfactory.

Forced Beans from Guernsey and Worthing are rather more plentiful and making less money. Hothouse Potatos maintain fairly good prices and are inclined to sell better. A few hothouse Peas are arriving and sell well. Considering the cold weather, Mushrooms are comparatively plentiful, and prices are not so high as might be expected. Cucumbers are not selling well, and there is some congestion of supplies, which means lower values to clear. Forced Rhubarb is selling rather more freely, and price-levels are a shade higher. Asparagus, mainly from France, is selling well, and the small quantity available from Devonshire is also moving out satisfactorily. Salads from France are going out freely in spite of some proportion of frozen produce. Cauliflowers are a bright section, even at improved prices. Root crops are merely a steady trade, as also are green vegetables, in spite of some shortage. Supplies of Potatos are ample for the demand, and values are about the same.

GLASGOW

Some improvement was noticeable last week in the conditions of the cut flower market, and price movements, although limited, were generally in favour of producers. Tulip supplies were ample and the quality was better. Bartigon, William Pitt and Le Notre realised from 8d. to 1s. 6d. for 6's; William Copland, 8d. to 1s. 4d.; Couronne d'Or, 10d. to 1s. 3d.; Flamingo and Prosperity, 10d. to 1s. 2d.; Cardinal, 10d. to 1s.; and Murillo, Prince of Austria, Lucretia and Tea Rose, 9d. to 1s. Daffodil prices were irregular, King Alfred making 2s. per dozen; Emperor and Victoria, 10d. for 6's; Golden Spur, 10d. to 1s. 2d. for 12's; Sir Watkin, 1s.; Princeps, 10d.; and ornatus, 6d. to 9d. Exceptionally good Carnations were cheap at 2s. to 2s 6d. per dozen, but the blooms of Betty Lou were worth from 7s. to 8s. Richardias and Lilium longiflorum ranged from 10s. to 12s.; Madame Butterfly Roses advanced to 12s. 6d. per dozen; Freesias sold at 1s. per bunch; Anemones and Ranunculi, 2s.; Lilac 2s. to 3s.; Prunus, 2s. to 2s. 6d.; Mimosa, 12s. per cane; Narcissi, 20s. per cane; Stocks, 8s. per pad; and Lily-of-the-Valley, 2s. to 2s. 6d.

In the fruit market, Apples averaged 2s. per barrel and 1s. per case cheaper, while Orange prices were steady. Grape Fruits (Blue Goose brand) sold at 26s. per case; home-grown Grapes, 3s. 6d. to 5s. 6d. per lb.; Belgian, 2s. 6d.; and South African, 15s. to 16s. (9 lbs.); Cape Plums, 5s. to 6s. per box; and Peaches and Nectarines, 5s. to 8s.

Vegetables were scarce and dear, Cucumbers being priced at 33s. per dozen; Lettuce, 4s. to 5s.; Cauliflowers, 4s.; French Beans, 6s. to 7s. per box; Leeks, 1s. per bundle; Mushrooms, 2s. 6d. per lb.; and Rhubarb, 30s. to 40 per cwt.

The Transport of Food Materials by Plants.

THE green plant illustrates the thesis that clever people find it much more difficult to understand simple things than complicated things. Science has been puzzled to explain how the movements of food materials are regulated in green plants. It is, of course, known that the seat of manufacture is the green leaf, and that the materials manufactured consist of sugars and nitrogenous compounds. These materials, to be of use, must be transported to all parts of the plant, and what the scientist wishes to know is the tissue through which this movement takes place. There are two routes, either or both of which might serve. They are the wood and the bast. The woody system of plants, however, serves other purposes. It acts as the skeleton and forms the channel through which water and mineral substances obtained from the soil are brought to the leaves. In view of this latter function, it does not seem likely that it should also be engaged in a circular downward transportation of food from the leaves. There is, however, some evidence that such a circulatory movement does appear in the woody vessels, and it is quite certain that sugars are to be found in the sap exuding from those vessels. Nevertheless, recent investigations seem to point to the phloem or bast as being the highway along which the sugary sap produced in the leaves travels to its destination, which is to all—including the uttermost—parts of the plant. These investigations have been carried out very carefully by *Messrs. Mason and Maskell, and their main conclusions are summarised very thoroughly by Professor J. H. Priestly in *Nature*, for January 26, 1929. Messrs. Mason and Maskell have shown in a very convincing manner that the daily variation in concentration of sugars in the leaf, coincides with similar variation in the bark. This would seem to indicate that as production in the leaf increases during sunlight, so surplus sugar is carried away along the bast. The chief puzzle, however, remains, which is,—how does the sugar travel? The rate at which it passes from the leaf down the stem is so relatively high as to preclude its passage by diffusion. Calculation shows that the speed of movement is about 20,000 times faster than it would be were it to pass by diffusion. The young sieve tubes, which are the elements of bast by which sugar appears to travel, consist of protoplasm which would often seem to be in a highly agitated state, and which, of course, in its peregrination might carry with it sugar from the sieve tube above to the one below. Of course, the rate of movement of protoplasm is comparatively slow, but it is of the order of an inch or so an hour, and such a rate in so leisurely an institution as a plant might suffice to provide for the distribution of all manufactured materials of a leaf before the annual growing period comes to an end.

After the Frost—a Thaw.—We ask the consideration and patience of our readers in the case of nurserymen from whom they are expecting the delivery of trees, shrubs and herbaceous plants for late planting. The nurseryman has his difficulties, and the long continued period of severe frost has added to them, but every nurseryman fills his orders so soon as possible, for his own sake, so well as his customers. Stock is so retarded that, when the thaw is complete, there will be ample time for successful planting.

The Genus Tulipa.—The friends of the late Mr. W. R. Dykes are aware that, for some time before his untimely death, his interests had turned to the Tulip genus, and they will be glad to know that Mrs. Dykes has lately been engaged in gathering together her husband's notes and papers on the genus, with a view to their publication in collected form in the course of the ensuing summer. It is understood that Sir Daniel Hall has written a preface to the book.

The Genus Eucalyptus. — We have recently received Part 10, Vol. VII (Part LXX of the complete work) of *A Critical Revision of the the Genus Eucalyptus*, by the late Mr. J. H. Maiden, F.R.S., F.L.S. The Eucalypti dealt with in this issue are E. Baxteri and its variety pedicellata, E. Blaxlandi, E. agglomerata, E. orgadophila, E. acmenioides var. tenuipes, E. Murphyi, E. Stuartiana and E. angophoroides. In most instances a full description of the plant is given, together with its synonyms and range.

United Horticultural Benefit and Provident Society.—The Annual Meeting of this Society will be held at the Royal Horticultural Society's New Hall, Vincent Square, Westminster, at 7.30 p.m., on the 11th inst.

Parks and Botanic Gardens Superintendents.—At the next meeting of this Association, to be held in the Lecture Room of the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Tuesday, March 12, Mr. R. Birch, of Messrs. James Carter and Co., Ltd., will deliver a lecture on "The Production and Maintenance of Grass for Public Parks." The chair will be taken by Mr. A. J. Ashmore (Chairman of the London Branch), at 7 p.m. prompt. This lecture should prove of interest to parks representatives and horticulturists in general, to whom a hearty invitation is extended.

Belgian Centenary Celebrations.—On February 27, a meeting took place at the Palais des Academies in Brussels to inagurate the commencement of active work in celebrating all over Belgium the centenary of her independence by means of intensive floral and horticultural production. "La Belgique Fleurie en 1930" is the slogan to be used to stimulate all classes of the population to show the visitors expected to attend the various exhibitions, etc., during the summer, a country of flowers and foliage. The official ceremony was organised by M. Albert Richir, President of the Provisional Executive Committee, and was graced by the presence of the Queen of the Belgians, attended by all the horticultural notabilities and a number of other distinguished persons. The Minister of Agriculture, M. Baels, was unfortunately absent owing to influenza, and more than two hundred letters and telegrams were received from other persons who were prevented from being present by the same reason. The Queen was welcomed and the proceedings opened by the Baron de Kerchove d'Exaerde, assisted by M. Richir and others, and several speeches were made, after which Committees were formed to take over the work of propaganda and organisation.

"The Gladiolus Annual."—All who are interested in the Gladiolus will welcome the 1929 edition of *The Gladiolus Annual*, the official organ of the British Gladiolus Society. It is a very creditable production, being well edited, well printed and freely illustrated; the coloured plates of single blooms of the varieties Paul Pfitzer, Mrs. van Konynenburg, and Phaenomen are exceptionally good. The one-hundred-and-twenty-three pages are packed with information, the articles of special interest being those dealing with Gladiolus species; Gladioli of Amercan origin; new Gladioli; and New Zealand Gladioli. The activities of the British Gladiolus Society are set forth, and there is a comprehensive report of the 1928 International Gladiolus Exhibition, by Mr. Charles W. J. Unwin. Mr. A. E. Amos, the Hon. Secretary and Treasurer of the Society, is to be congratulated upon the production of so creditable a work, copies of which may be obtained from him; his address is 10, Bergholt Road, Colchester.

Massachusetts Horticultural Society.—As the present year marks the centenary of the Massachusetts Horticultural Society, the Trustees of the Society have had a special medal struck for award during 1929. This Centenary Medal will be struck in gold, silver and bronze, and the number made will be limited to one hundred. It was designed by the eminent sculptor, John Francis Paramino, its face side being a reproduction of the Society's emblem, a representation of the goddess Flora distributing her gifts of flowers and fruits over the earth.

Flowering Plants at Kew Gardens. — With everything in the open garden frozen and very bedraggled in appearance, visitors to the Royal Botanic Gardens, Kew, are glad to turn their attention to the glasshouses where, especially in the Flowering-plant House (No. 4), pleasure can be found in the various beautiful subjects there to be seen. For, despite the almost heart-breaking conditions with which those responsible for the display in this house have had to contend, the chief difficulty being the lack of light, there is yet a splendid variety of plants in flower, for it would appear that Mr. J. Coutts, under whose guidance the continued floral display in this house is maintained, has a penchant for discovering uncommon subjects which will respond to glasshouse treatment and prove effective during the winter months. Among other things, he is getting together a fine collection of Cape Heaths, and has already secured a good stock of a large number of uncommon species, among them being the beautiful rose-pink-flowered Erica umbellata, which has been lost to cultivation for many years. The work of maintaining this succession of flowering plants is no easy task, as is evidenced by a tour through the several pits in which they are housed previous to transference to their flowering quarters, and it is surprising how generally healthy in appearance the various occupants of the pits are. For instance, we noticed, among others, grand batches of the beautiful Primula kewensis, just coming into flower, also P. Forrestii, as yet showing no signs of blossoming, but apparently responding very well to pot culture, while two very charming flowering shrubs were Coleonema album, suggestive of a shrubby Veronica, with slender, twiggy growths furnished with small, slender leaves and terminated by little clusters of diminutive, white flowers; and Pentapterygium serpens, whose long, leafy and hairy growths were closely packed on the undersides with pendulous, tubular, pale red flowers. The bad effects of the weather on the various Begonia semperflorens hybrids, were obvious, for these, usually laden with blooms at this season, were very sparsely flowered. On the other hand, some two-year-old specimens of Begonia manicata were magnificent, being crowded with graceful sprays of flowers in a delightful shade of soft pink. This would seem to be an extremely useful winter-flowering Begonia for districts where fogs and a general shortage of light is experienced during the winter. Eranthemum pulchellum is just commencing to open its spikes of rich violet-blue flowers and should, in a week or so, be very attractive, while in the beds in the central portion of the house, several specimen Camellias were in full bloom. Another shrub of interest was Ardisia crenata, heavily laden with scarlet fruits which will keep fresh and bright for a period of at least twelve months; while a bright display is also afforded by the Hippeastrums, in many rich and delicate shades. Senecio Petasites and S. grandifolius, both from Mexico, were also worthy of note. The former has been in bloom for over six weeks, and the tall trusses of rich yellow flowers are as attractive as ever, its handsomeness being further enhanced by the large, very Petasites-like leaves. S. grandifolius also has handsome foliage, large and glossy, and rich green, its inflorescence being a crowded head of small, yellow flowers. Several Acacias and Heaths were in flower, also some striking colour forms of Cineraria cruentus, while Pomaderris elliptica, a bushy shrub about three feet high, was heavily laden with flower buds and should present an attractive spectacle in a week or so. Among the most striking subjects in this house were the grand plants of Rhododendron obtusum and R. Kaempferi, in many forms, each plant being literally a mound of blossom, brilliant and striking. Epacris longiflora var. superba was flowering, also the uncommon but rather attractive Veltheimia viridiflora, while, facing one of the doors was a splendid group of Clivia miniata varieta, with large umbels of bright orange-cerise blooms. Primula malacoides and P. effusa were flowering sparingly, but the Tulips, William Copland and La Notre, were extremely fine, while colour was also provided by the fragrant blooms of the Freesias, just commencing to open, Cyclamens, Crocuses in variety, Richardia africana, and Hyacinths in several shades.

---

* *Memoirs of the Cotton Research Station, Trinidad, Series B*, Physiology, No. I. "Studies on the Transport of Carbohydrates in the Cotton Plant," by T. G. Mason and E. J. Maskell. Empire Cotton Growing Corporation, 2, Wood Street, Millbank, London, S.W. 1. 1928.

Trials of Chrysanthemums and Gaillardias at Wisley.—The Royal Horticultural Society will carry out trials of early-flowering Chrysanthemums and of perennial Gaillardias in their Gardens at Wisley during the coming season. Three plants of each variety for trial should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before April 6, 1929.

International Institute of Agriculture.—The International Institute of Agriculture, Rome, in pursuance of the suggestions made by the recent General Assembly, has introduced important modifications in the contents of the International Review of Agriculture, with the object of increasing its interest and value. The principal aim of these alterations is to replace isolated or fragmentary items of technical, economic or legislative information by comprehensive studies based on the information available at the Institute, giving a general review of the actual situation in questions of international importance, and having an up-to-date character or being of practical interest for agriculture. As from January 1, 1929, the *International Review of Agriculture* will appear in three separate parts, viz., (1) Monthly Bulletin of Agricultural Science and Practice; (2) Monthly Bulletin of Agricultural Economics and Sociology; and (3) Monthly Crop Report and Agricultural Statistics. The Institute has also, as from January, 1929, re-established the monthly publication of the *International Bulletin of Plant Protection*, which was suspended in March, 1928.

Mr. William Atkinson, V.M.H., J.P.—About fifteen months ago, we published a portrait and biographical notice of Mr. W. Atkinson, head of the firm of Messrs. Fisher, Son and Sibray, of Sheffield. We give Mr. Atkinson's portrait again so as to keep our gallery of Victoria Medallists as complete as possible, as he has now joined the distinguished horticulturists honoured by the Royal Horticultural Society, and entitled to place the magic letters "V.M.H., after their names. Mr. Atkinson is, perhaps, better known in the midlands and the north, than in the south, but his friends everywhere will join in congratulations upon the high honour recently conferred upon him.

MR. W. ATKINSON, V.M.H., J.P.

Haarlem Daffodil Show.—The General Dutch Bulb Growers' Society will hold a special Daffodil Show at Haarlem, on April 17 and 18. Gold, Silver-gilt, Silver and Bronze Medals will be awarded to deserving exhibits, while certificates and awards will be granted to new Daffodils that meet with the approval of the Committee. The Secretary is M. H. Voors, Krelagehuis, Haarlem.

Legacies to Gardeners.—The late Mr. George Acton Davis, J.P., of Julian Hill, Harrow, who died on January 22, left £100 to his gardener, Mr. George Summerfield.

Association of Economic Biologists.—A meeting of this Association will be held at 2.30 p.m., on the 15th inst., in the Botanical Lecture Theatre of the Imperial College of Science and Technology, South Kensington. At this meeting Sir John Russell, F.R.S., will deliver an address on "Some Agricultural Problems in Australia," and F. L. McDougall, Esq., C.M.G., will lecture on "The Commonwealth Council of Science and Industry in its relation to Agriculture." Students of biology are cordially invited.

"The Gardeners' Year Book, 1929."—This useful annual publication, edited by Miss D. H. Moutray Read, and published by Messrs. Philip Allan and Co., Ltd., 69, Great Russell Street, W.C.1, price 5s. net, may well be described as a *pot pourri* of information, much of which is of topical interest to gardeners. Horticultural events of interest during 1928 are recorded, together with short accounts of the various plant-collecting expeditions which were conducted, while other portions of the book are devoted to descriptions of the various botanic gardens, and information concerning the numerous horticultural institutes and colleges, societies, new and noteworthy plants, horticultural publications, etc. Part 2 deals with various cultural topics. The publication represents much labour on the part of Miss Moutray Read, for it has been carefully prepared and excellently printed.

Sodium Chlorate as a Weed-killer.—Farm crop investigators, at the head of whom is Mr. H. D. Hughes, at Iowa State Agricultural College, Kansas, have discovered an effective weed-killer which will destroy Quack Grass, Canadian Thistle, Horse-nettle and Field Bindweed. Many different materials had previously been tried to control the Field Bindweed, which was literally over-running whole farms in Kansas, but it has now been found that sodium chlorate will entirely kill the roots as well as the tops, in spite of the fact that the roots sometimes penetrate the soil to a depth of four feet. It has also been found that sodium chlorate applied in the late autumn kills all Canadian Thistle and the land produces good crops the following season. The chemical is explosive when it becomes thoroughly dry, if it is mixed with fine material, such as dust on clothing, or chaff. Care has, therefore, to be exercised when using it. The quantities used are not given, but the interesting statement is made that calcium chlorate, which has no tendency to explode, may be expected to give as good results as sodium chlorate.

Kent Playing Fields Association.—At the Annual Meeting of the Kent County Playing Fields Association, held at Maidstone recently and presided over by Lord Camden, it was announced in the Annual Report that, although no special appeal for funds has been issued in the past year, the sum of £2,449 had been received in donations, bringing the total amount received up to £13,262. Lord Camden stated that the playing field movement continued to make good progress in Kent, and he referred especially to the keen interest taken in the movement by the Prince of Wales. Lord Camden was re-elected President of the Association.

Horticultural Club.—A Club Dinner and Lecture will be held at the headquarters of this Club, St. Ermin's Hotel, Caxton Street, Westminster, on March 12, at 6.30 p.m., for 7 p.m. The price of the dinner is 6s. 6d., exclusive of wines. Following the dinner, Mr. R. E. Cooper will deliver an address, illustrated by lantern slides, on "Botanizing in the Himalayas."

Seed Potatos.—The National Institute of Agricultural Botany has made an examination of the Potato sections of a representative selection of the seedsmen's catalogues and lists for 1929. Stocks of Potatos under many of the names which appear in these publications have been grown by the National Institute of Agricultural Botany at the Potato Testing Station at Ormskirk in recent years, and have been adjudged by the Institute's Synonym Committee to be "synonymous" with well-known established varieties. It is too early to determine whether in 1929 the varieties named below are again synonymous with the type varieties set against them or with some other established variety, or whether they are, in fact, distinct. Prospective purchasers are advised to satisfy themselves by enquiry or guarantee that such varieties are distinct from, or are, indeed, of greater value than, their presumed types. Nor is a so-called "selected" or "improved" stock of an established variety, whether offered for sale under its original, or under a new name, to be accepted as an improvement without evidence of adequate trial or sufficient guarantee. The name of the type variety is given first, followed by the name or names of synonyms:—Abundance: New Renown; Ally: Goldfinder; Bishop: Advancer; British Queen: Beauty of Essex, Irish Elegance, Royalty and White Stone; Coronation: Crown Jewel; Duke of York: Cherub, Chester Early, Midlothian Early, New Success, St. Paul, Victory and Western Hero; Great Scot: Dreadnought, King John and Lord of the Isles; Immune Ashleaf: Improved Ashleaf; Red King Edward: Cleadon Park, Mons Star; Royal Kidney: Guardian and King of Potatos; Sharpe's Express: Alpha, Earliest of All, Early Favourite and Express; Sharpe's Victor: First Crop; Eclipse (or Sir John Llewelyn): Colonist, Nun Nicer; Snowdrop: First Crop; Stirling Castle: Mighty Atom; Up-to-date: Factor, Longkeeper, Prosperity, Scottish Triumph, Sensation and Tremendous.

Horticultural Congress at Nice.—The tenth Congress of the French National Federation of Horticultural Societies is to be held at Nice this year, on March 30 and 31, under the auspices of the Nice Horticultural Society, which is also arranging to organise an International Horticultural Exhibition. Problems of interest to horticulturists will fill the agenda of the Congress, including the disinfection and sterilisation of soils, the practical organisation of exhibitions, and horticultural apprenticeship, as well as other questions of rather more local horticultural interest, such as the introduction of exotic plants on the Côte d'Azur. To occupy the two days following the Congress, *i.e.*, April 1 and 2, an excellent programme of visits and excursions has been arranged to enable visitors to see the numerous beauty spots in the Alpes-Maritimes.

National Mark for Exported Broccoli.—Until about three years ago, it is stated by the Ministry of Agriculture, the Broccoli produced in Cornwall was raised from local seeds, with the result that the firm, white curds which distinguish the best type of Broccoli, was not apparent in a large proportion of the crop. During the past two years, however, and acting on the advice of the Ministry, better strains have been adopted by the Cornish growers, with the result that Cornish Broccoli is now second to none, and is regarded as likely to find a ready market in Germany and Belgium, and attempts are now to be made upon the exportation of the Broccoli to these countries. With this purpose in view, the various authorities concerned have drawn up a scheme for the grading and the marking of the best export produce with the National Mark.

French Rose Congress at Lyons.—No other town having been specially selected as the venue of the 1929 session of the French Rose-growers' Society, M. Silvestre, the President of the Society, has requested that it be held at Lyons, and his proposal has been unanimously adopted, the more so as it has not taken place at that city since 1912. The dates for this Congress will be arranged to coincide with the annual Lyons fair.

New Rose Competition at Barcelona.—An international new Rose competition is being inaugurated in Barcelona, Spain, in the gardens of the Royal Palace of Pedralbes, with the permission and patronage of the King, who has also offered several prizes. The competition is being organised by the Barcelona municipality, and will be especially interesting on account of the climatic conditions of the Mediterranean city. The Roses will be planted in the open, in the Royal park, which is closed to the public, and tended by members of the public parks staff. There are to be fourteen judges, of whom six will be foreign—one each from England, the United States, France, Germany, Luxemburg, and Holland. M. Forestier, who organised the international Rose trials conducted at Bagatelle, near Paris, will also be asked to accept office among the judges. The King of Spain has offered a large Gold Medal which will be awarded each year to the best foreign Rose, and in the event of a Spanish-grown variety also meriting it, a similar Gold Medal will be awarded thereto. In addition, other awards will be made for certain special features. The municipality will acquire 150 of the best Roses to form the nucleus of a permanent collection and will entertain for five days each year the foreign members of the judging committee.

The "Best Six."—Messrs. G. Bunyard and Co. have issued a catalogue of such unique character that it merits a special note. The catalogue is entitled "Bunyard's Best Six," and it is published "in the interests alike of the beginner, the connoisseur, and the busy man." It contains lists of what the Maidstone firm considers the six best flavoured dessert Apples, cooking Apples, cropping Apples, tender-fleshed Apples, and latest dessert Apples; the six best-flavoured Pears, and best croppng Pears; the best six self-fertile dessert Plums; best six Gages, and the best Plums for bottling. Then follow lists of the best six Irises at stated prices, Delphiniums, Michaelmas Daisies, border Carnations, Phloxes, Paeonies, flowering Cherries, evergreen foliage shrubs, shade trees, weeping trees, early-flowering shrubs, new Barberries, new Brooms, hardy Fuchsias, Lilacs, Clematis, and flowers for drying for winter decoration, making up altogether a very handy and instructive booklet.

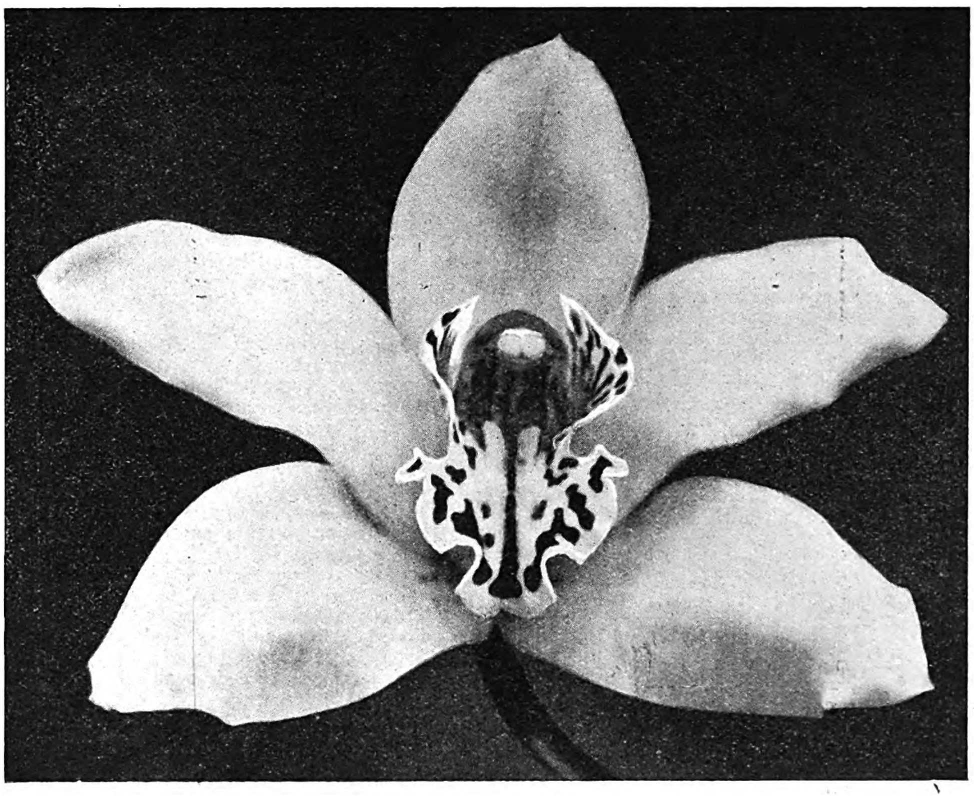

FIG. 87.—CYMBIDIUM LETTY, WYLD COURT VAR.

R.H.S. First Class Certificate, February 26. Flowers white, with purplish-brown markings.

(see p. 168.)

Appointments for the Ensuing Week.—Monday, March 11: East Anglian Institute of Agriculture lecture; Birmingham and Midland Gardeners' Association's lecture; Derbyshire Horticultural Association's meeting; Harrogate and District Horticultural Association's meeting; United Horticultural Benefit and Provident Society's Annual Meeting. Tuesday, March 12: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting. Wednesday, March 13: Sheffield Chrysanthemum Society's lecture. Thursday, March 14: Derbyshire Horticultural Association's Annual General Meeting. Friday, March 15: Manchester and North of England Orchid Society's exhibition; Association of Economic Biologists' Council meeting and lecture; Saturday, March 16: Leeds Paxton Society's Tulip Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Caution.*—Some forty years ago, a few Frenchmen opened a shop in St. James's Street for the sale of miscellaneous plants, and amongst other "nouveautes" sold a baronet a "yellow moss" Rose at five guineas a plant. Between that time and the spring of 1852, I heard nothing of a similar swindle; but in March of the year just mentioned (in Bond Street) two of these scamps sold a friend of mine a collection of new Roses "vary sheep" as they "most go avay," not one of which was otherwise than the veriest rubbish—a plant or two of common Moss and red Provins worked on dwarf stocks being the cream of the purchase. This year, in Regent Street, another "Horticulteur et Fleuriste" has recently commenced victimising the public, an amateur of some standing having bought there last week "Mousseuse Jaune," at the low price of one guinea a plant. I need say no more to convince your readers of the manner in which their pockets will be picked should they venture into this magazine. *C. G. Wilkinson, Western Rose Nursery, Ealing.* We print this. But such warnings are perfectly useless. The crop of fools is inexhaustible. *Gard. Chron., March* 11, 1854.

Publications Received.—*The Lilac: A Monograph*, by Susan Delano McKelvey, pp. 581, with 172 half-tone plates and four colour charts; The Macmillan Company, New York; price £3 15s. 0d. net.—*Nature in Field and Meadow*, by W. Percival Westell, The Sheldon Press, London; price 2s. 6d. net.—*Daily Mail Garden Plans*, edited by P. W. D. Izzard; Associated Newspapers, Ltd., price 1s. 6d.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN-MOORE Manchester.

Vanda Amesiana.—This distinct, dwarf-growing species produces its fragrant blooms at various seasons, although the majority are produced during the early part of the year. Many plants are now developing flower spikes, and will require a larger quantity of water at the roots than hitherto, while if the plants are placed in a warmer temperature it will assist the development of the flowers. Remove them, however, to cooler and drier quarters when the blooms have expanded, for under such conditions they keep perfect for a considerable time. When they have finished flowering, the plants should be grown in a light, airy position in the intermediate house. As the hours of sunlight increase, occasional spraying with tepid water is beneficial, and so soon as the roots are active, fresh rooting material may be afforded. If the plants have lost their lower leaves and are inclined to be "leggy," they should be carefully removed from the receptacle, first loosening any good roots that are attached to it, and cutting away the lower portion of the stem to a point immediately below some good fresh roots, the plants then being repotted. Fix the stem well down in the receptacle, and then half fill it with drainage, filling the remaining space with a compost of equal parts of Osmunda fibre and Sphagnum-moss, adding lumps of charcoal to keep it open and finishing off with some clean heads of fresh Sphagnum-moss, pricked into the surface. This latter helps to retain moisture later in the season. Plants that do not require repotting should have any sour compost removed and fresh material afforded.

Cattleyas and Laelio-Cattleyas.—The increased hours of sunlight will prove beneficial to this group of Orchids, as many kinds are producing flower stems at the base of the sheaths formed in the late autumn months. In districts where the sunlight is not particularly strong the flower stem will often remain stationary for long periods, with the result that they sometimes decay, and the season's flowers are lost; this may generally be prevented by carefully opening the sheath, from the top down to the bud, but not opening it completely, as that would probably damage the stem at this stage of growth. Water should be afforded the roots in small quantities as the compost becomes dry until the flower buds are increasing in size, when an increased quantity will be needed to assist their full development. Scale insects increase rapidly at this season and soon do considerable harm, therefore they should be removed so soon as detected. As the plants pass out of flower the thick, fleshy sheath and flower stem should be cut off fairly close to the top of the pseudobulb, and the exposed parts dusted with powdered charcoal to prevent decay, which often sets in at this stage if a spell of dull weather is experienced.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Permanent Vines.—The shoots of these having been tied down and stopped at the second joint beyond the bunch, next proceed with the pinching of the laterals, at the same time retaining intact the one nearest the extremity for laying in if there is room for extension, but being careful not to retain more leaves than can have full exposure to light and air. In later houses fertilisation must receive careful attention, a constant circulation of semi-dry, warm air being essential to a good set of Grapes; the temperature when the flowering stage is reached should be raised to 65° by night for Black Hamburghs, and 70° for Muscats, that by day ranging 10° higher from fire-heat and about 80° to 85° or 90° when the sun is bright and the external air soft and mild. When vines are in flower, just enough fire-heat should be employed to raise the temperature to the above figures, and a circulation of air, not a cold current, should be maintained, while the floors should be damped with warm water as an arid atmosphere is detrimental to setting. All Grapes are improved by artificial fertilisation. Muscats and Buckland Sweetwater, known to be shy setters, may be assisted greatly by charging a camel-hair brush with Black Hamburgh pollen and going lightly over the bunches every day at noon, or whenever the temperature has reached the maximum.

Thinning Grapes. — The thinning of Black Hamburgh, Foster's Seedling and Madresfield Court comes first, and the capabilities of each vine should be well understood. Like all other operations, thinning should be commenced before the superfluous berries have time to rob those which must remain. Free setters may be thinned fairly freely, and the nearer the approach to the retention of the correct number, the larger will be the berries when ripe. Muscats and other shy setters should be well fertilised before being thinned, as nothing detracts more from an otherwise perfect bunch than a number of seedless berries, and perfect berries always seem to fill up the space if the former are removed at the beginning. All Grapes vary much in closeness of bunch and size of berry, and only those in charge can tell how many berries to leave; each bunch should be full enough to retain its form when cut and placed on the table.

Successional Vines.—These, if now breaking, may be syringed well until the flower bunches are prominent. If the inside borders have not been watered since the house was closed, a good watering with weak liquid manure for old vines, and pure water at a temperature of 80° for young ones, should keep them going until the Grapes have set. After the vines are disbudded and tied, a rise in temperature to 60° by night and 70° by day, and 5° to 10° more under bright sun, should help to draw out the bunches, which should be reduced to one on each shoot.

Ventilation and Temperatures.—After all Grapes are thinned, make allowance for increasing length of days by keeping up the temperatures when the weather is bright and mild; air at night is a great help, even if afforded only in small quantity. The ventilators should be closed early to ensure the full benefit from damping the paths and borders. As the temperature rises, air may be given at 70° and steadily increased as the thermometer rises to 80° or 85°. The great secret of ventilation at this early season is the maintenance of a steady rise in temperature, and early closing to trap the sun-heat. Moisture is necessary to ensure that no scalding or scorching of the shoots will take place after the house is closed for the day at this early season.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens; Wisley, Surrey.

Delphinium Varieties.—The selection of varieties of Delphiniums is a matter of individual taste; some prefer the pale lavender sorts, others the dark blue. Some two-hundred-and-thirty-four varieties of Delphinium were tried here in 1925 and a selection of the best in the various colour groups may be of value to intending planters. Of the Belladonna type, varieties of which are charming as border plants, producing more side-growths than those of the Elatum type, Belladonna grandiflora Captivant, pale sky-blue; Nassau, light blue; Mrs. J. S. Burton, bright blue; and Mrs. Thomson, bright blue, are the most useful. In the Elatum type, which seems to be the most popular, many shades of blue are represented. Among pale blue sorts, the best are Sister Clare, Queen Mary, Blue Princess, Lize and Mrs. Townly Parker; while the most striking of the dark blue sorts are Blue Boy, Corry, Blue Bird, Constance, Hugh Mitchell and Col. Douglas. A selection of those with flowers in shades of mauve should include Mrs. Colin McIver, Glory, Mrs. Shirley, Col. Sir Wyndham Murray, Jean, Marjorie Ferguson, Nora Ferguson, Mrs. A. T. Watson, Millicent Blackmore, and Winsome. Of the dark blue and dark mauve sorts, Lord Derby, Mrs. H. Kaye and F. W. Smith will be found reliable sorts. Violet Queen, King of Delphiniums, Mrs. Greighton, Edward Bromet and Sir Douglas Haig are good varieties of violet and deep purple colouring. A few of the species, although not so showy as the vigorous hybrids, add interest to the garden. D. cardinale has bright scarlet flowers, and is a desirable plant for the centre of the border. D. nudicaule has wonderfully dazzling scarlet flowers; it is quite hardy, but likes a position in a well-drained, warm border. It grows from one to two feet high and should be planted in clumps at the front of the border. D. chinense is an attractive dwarf plant, producing its bluish-purple flowers with great freedom, and will be found most useful for furnishing beds or narrow borders.

Hardy Annuals.—These should be sown so soon as the ground is in a workable condition, as they give better results if given time to become well established before dry weather sets in. It is necessary that the preparation of the ground for these, as well as other crops, should be thorough. Seeds of annuals are so cheap, and usually of such good germinating power, that the average grower is inclined to be over liberal with the quantity used, and when the time for thinning arrives, this work is often neglected until it is too late. Prepare the ground well and sow the seeds in lines at least a foot apart to facilitate hoeing when the plants are small. Thin the seedlings early and periodically until the desired distance apart is reached, and stake those that require support early. When thinning, remove the weak and badly placed plants to begin with. A distance of nine to twelve inches apart is none too much for the majority of annuals, if well-grown, and double that distance will be required for such subjects as Shirley Poppies, Cornflowers and the tall, branching Larkspurs. Where these were sown in the open during autumn and have withstood the recent severe weather, the beds will now require attention. Plants grown under such conditions develop to a much greater size than those sown now, and the true habit and beauty of many annuals is only realised when it is possible to adopt this method of cultivation. A few of the best for autumn sowing are Shirley Poppies, Clarkias, Nemophila, Godetias and Larkspurs.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Pruning.—All pruning delayed by the recent severe weather should be completed so soon as possible, but under no circumstances should pruning be carried out in frosty weather, or many of the buds intended to produce leader growths on Apple and Pear trees will either be killed or severely injured, thereby affecting the shape of the tree. The angle of the subsequent growth from the leading bud can be altered considerably by the way in which the growth is pruned. The leader growths on upright-growing Apples, such as Annie Elizabeth, Chelmsford Wonder and Christmas Pearmain should be cut quite half-an-inch beyond the desired bud. The "snag" thus left will tend to push the resultant growth outward in quite a marked degree. Trees of more spreading habit are sometimes best cut to an inside bud, as with Peasgood's Nonesuch, or to one on the outside, but as small a "snag" as possible should be left, so as to allow the leading growth to continue on in the same line of growth. In every case, prune to a bud pointing in the direction the leader is required to take. In the case of fruit trees planted this season, there is always the question as to whether they should, or should not, be pruned this spring. In every case this must be decided by the pruner. There are a few vital points which must be considered. If the trees are young and in good soil, and if the planting was carried out last autumn, there need be no hesitation about cutting the growths back fairly hard this spring; delay the pruning, however, until the sap is flowing actively. If the trees are older, or the soil is none too fertile, or the planting was delayed until the spring, there should be little or no cutting of the leader growths this season; if leader growths are unduly long they may, however, be tipped with advantage. The uppermost buds will grow out and develop fruit buds, but those behind will remain dormant, and it is to one of these dormant buds that the growth should be pruned next winter, with the full assurance that perfect leader growths will be produced. In the case of spur growths, no such measures need be taken. Late-planted trees should, after the recent severe weather, have the soil made firm about them, and be mulched with long, strawy manure, which should be renewed later if a dry season ensues.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain,
Brocket Hall, Hertfordshire.

Euphorbias.—Euphorbia fulgens (jacquiniaeflora) and E. pulcherrima (syn. Poinsettia pulcherrima) are, to my mind, two of the most useful plants to grow under glass for winter decoration. The brilliant scarlet bracts prove a great attraction, while the soft colour of E. p. rosea is very pleasing. The white variety of this species does not always produce pure white flowers, but it is more easily grown and will last for a considerable time when cut. The old stools should now be cut hard back and kept somewhat dry at the roots for several weeks, when the roots may be slightly moistened and the tops frequently syringed with tepid water to induce young growths to form for use as cuttings. During the resting period it is not wise to place the plants in a house having a low temperature, especially E. fulgens, for this species requires a temperature not lower than 50°. This applies to pot-grown plants.

Stock Plants.—During the next two months or so many of the winter-flowering pot plants will require attention with regards to propagation, and the ultimate success of many of these subjects will depend on the treatment meted out to them after they have passed out of flower. The following plants may now be cut hard back to induce the formation of strong, healthy shoots for cuttings:—Eranthemums, Eupatoriums, Lasiandras, Plumbagos, Salvia splendens and Jacobinias. Cuttings of most of these subjects will root quite easily if inserted in sandy soil, around the sides of the receptacles, and stood in a propagating frame in a temperature of 60° to 65°. Various winter-flowering Begonias and many other useful plants may soon be taken in hand with a view to securing good cuttings.

Solanum Capsicastrum.—This useful fruiting plant often proves of great service for indoor decoration during the winter months. Seeds may now be sown in a warm house, where germination will soon take place. Where a good strain of this plant exists it may easily be propagated by means of cuttings. The seedlings or cuttings should be kept growing freely during the early stages of growth, to allow the young shoots to be pinched several times to promote a bushy habit. Old plants may also be cut back and grown on again the second year; in fact, they often make the best plants when so treated. During the summer months the plants may be stood in a cold frame, the lights of which may be removed except when heavy rain is falling.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder,
Knowle Gardens, Dunster, Somerset.

Broad Beans.—Another batch of Broad Beans should be sown, sowing a larger quantity of seeds than previously; the present sowing should be for the production of the main crop. The Broad Bean repays generous cultivation by producing heavy crops of fine quality. Allow two-and-a-half feet between the rows, and eight inches between the plants.

Early Carrots.—These should be sown in shallow drills ten inches to one foot apart, on a south border. For sowing the seeds, choose a day when the ground is dry and in good working order, taking care that the soil has been forked well and a fine tilth produced.

Chives.—These will now be commencing to grow, and if a fresh bed is required, the present is a good time to lift and divide them. If cut regularly, a supply of leaves for flavouring and salads should be maintained for a long time.

Herbs.—Herbs to be raised from seeds should be sown now in boxes, and raised under glass in heat. Thyme, Tarragon and Mint may be lifted and divided, if an increase in stock is desired.

Potatos.—More Potato sets for planting shortly should be set up in boxes for sprouting, and placed in a little warmth. Another batch should be put in frames to maintain a successional supply of tubers. Early Potatos in pots will now need top-dressing with soil enriched with an approved fertiliser.

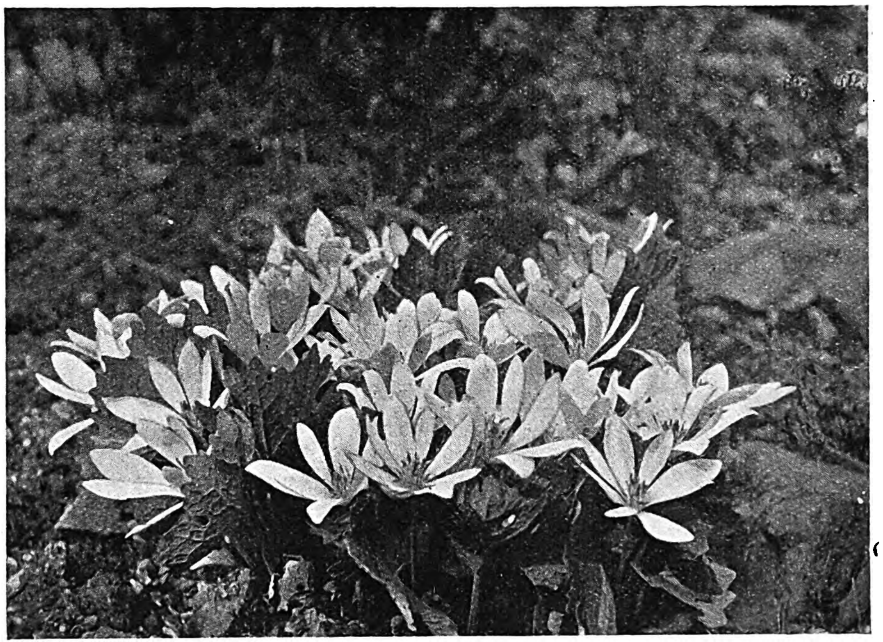

FIG. 88.—SANGUINARIA CANADENSIS VAR. GRANDIFLORA.
(see p. 178.)

Seed Sowing.—If plenty of frames are available, another sowing of Brussels Sprouts, Cabbage, Cauliflower, Lettuce, Leek and Savoys may be made in beds. The raising of these subjects in frames is preferable to sowing them in the open garden, where the seedlings are liable to be damaged severely by finches, linnets, etc.

Seakale.—To maintain a supply of Seakale, a batch of roots should be put in every two weeks, either in boxes or large pots. Keep the roots moist and well-covered up. Syringe them every morning and evening, and maintain a temperature of 55° to 60°; too high a temperature will cause them to grow too quickly, the growth, as a result, being thin and weak.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq.,
Rosemount, Monkton, Ayrshire.

Strawberries.—The ground between the Strawberry rows should be stirred with a hoe, or, if necessary, a fork, and a good dressing of half-decayed stable manure applied as a top-dressing; this serves the purpose of feeding the plants, and after it has been well washed with rain it keeps the fruits clean, and also helps to conserve moisture in the soil during dry weather.

Raspberries and Black Currants.—Where new plantations of these have been made, cut the canes of the former down to six or eight inches from the base to encourage the formation of good, strong canes the first season. Young Black Currant plants should also be cut back severely, for the whole future of the plantation depends on a really good growth the first year.

Vegetables.—The beds of autumn-planted Cabbages, autumn-sown Onions and Spinach should be hoed at frequent intervals, and a little fertiliser dusted between the rows will assist growth, but nothing of a forcing nature should be given until danger from frost is past. Where desirable, autumn-sown Onions may be transplanted, but they are much too liable to bolt to make transplanting really worth while.

Border Carnations.—If planted in their permanent quarters last autumn, these require attention after the frosts, as they are often lifted out of the soil during frosty weather, especially if not too well rooted. If pressed back into place and a little dry soil is placed around them, they soon take root again. The same remarks apply to most subjects planted out last September or later.

Hardy Primulas.—Where stocks of these have been raised from seeds, no time should be lost in placing the plants in their final quarters. True, these Primulas should have been planted out in autumn, but the seasons in the north are most unkind to this delightful family, as few of its members survive the alternating frost and rain, so that one finds it best to plant them out at the earliest possible moment in spring, making sure they are moved with plenty of soil adhering to the roots. Most of these Primulas like partial shade in summer and a cool root-run, and under such conditions few of them fail to attract attention.

Early-flowering Chrysanthemums.—Cuttings of these should now be rooted in boxes of sandy soil, surfaced with a layer of clean sand. Select suckers about three inches in length for this purpose. They may be rooted in a temperature of 65° to 70°, but should be removed to cooler quarters so soon as roots are produced and new growth is visible. Keep them near the glass and rebox or pot them before they become crowded, as they are better left unstopped until a fortnight or so after planting out, this being generally done about the first week in May.

ALPINE GARDEN.

SANGUINARIA CANADENSIS.

There is no more delightful plant for a cool place than the Canadian Bloodroot, and it combines with its chaste loveliness an amiable disposition, unquestionable hardiness, and the great merit of living for ever, and that without asking any attention. S. canadensis appears in spring, the single, bluish-grey and rosy-green leaf enclosing the rising flower in a pointed scroll. Then the beautifully-lobed, palmate leaf expands, disclosing as it does so the snow-white flower in the sheltering embrace of its opalescent cradle. Slowly extending its stem, the flower eventually stands well above the leaf, so that a cluster of plants gives the appearance shown in the illustration (Fig. 88). These blooms are rather more than an inch in width, but there is a considerable variation in the species in this respect, the best form that I have been able to acquire being sometimes listed as S. c. grandiflora (majus). This is rather later-flowering than the type, as May often arrives before the flowers are fully developed, and these are about eight inches high.

Although it is generally regarded as a woodland plant, I find S. canadensis does much better where it gets a fair share of sun, always provided the soil is cool and enriched with some leaf-mould or other retentive vegetable matter. Seeds are produced in quantity, and this affords the best means of propagation. Germination is not so free as one would expect it to be, and I have never yet seen a self-sown seedling. But a moderate proportion may be raised by sowing the seeds in a pot of sand and leaf-mould placed in a cool frame or covered with a pane of glass in a shady spot.

S. canadensis was introduced so long ago as 1680, but it does not seem ever to have been other than uncommon in gardens generally. It is one of the Poppyworts (Papaveraceae) and is familiarly known in America as the Puccoon. *A. T. J.*

CAMPANULA KOLENATIANA.

It is unfortunate that the lovely Campanula Kolenatiana is one of the monocarpic members of that invaluable genus, the Campanulaceae, as its attractions are such that once it has flowered it is difficult to content oneself with its absence from the garden. The propagation of this class is apt to be overlooked and unless seeds are saved or plants again purchased from a nursery, a gap will be visible where this beautiful plant once flourished. But this Campanula is worthy of a considerable amount of care and trouble and, as it is in commerce, I should advise those who know it not to secure a plant or two this spring. The late Mr. Farrer thought highly of it, and his description is so alluring that the present writer, who prefers the perennial to the biennial species, was induced to cultivate it, and much enjoyment followed when C. Kolenatiana came into bloom.

In its native habitats in the Caucasus it is found in rocky places, and in English gardens should have a light, stony soil and a sunny position. It has a strong root-stock, which produces a number of branching stalks with scalloped, heart-shaped or oval, basal leaves, and when the plant comes into bloom it forms a ball of large, violet-blue flowers, nodding gracefully over the plant. *S. Arnott.*

SEDUM PRIMULOIDES.

A native of Yunnan, where it was collected by Forrest, this Sedum is so distinct that it is hardly likely to be confused with any other. It is a partially deciduous species, making a compact little plant about three inches high, each of the many rather woody growths terminating in a dense rosette of fleshy, bright green, pointed, obovate leaves, barely a quarter-of-an-inch in length. The flowers, which are borne in August at the ends of short, leafy shoots springing from the base of the rosettes, are cone-shaped and pure white. Dr. Lloyd Praeger points out that this interesting species is closely allied to S. Praegerianum, and that it is apt to lose its very dwarf and alpine character under cultivation, and to become looser and more branched. It appears to be hardy enough in the usual sense, but the change of habit alluded to seems to be its undoing, for it is not an easy plant to keep. Dampness is apparently the cause of the trouble and here, in the humid west, I find it particularly apt to rot away in winter. Even the protection of a pane of glass does not always prevent this. My longest-lived plant was growing among some loose stones at the base of a dry south wall, but it eventually went as others have done. A dry moraine, with a winter covering of glass, would probably suit this species best. *J.*

SIDERITIS EUBOEA.

The genus Sideritis is not well represented in British gardens, and few of its members are really of sufficient value to induce us to make room for them when there are so many plants of superior effect. Of the hardy species described, S. euboea is the only one which seems to be available, and even that species seldom finds its way into gardens, possibly because it is rarely offered by the trade. The Sideritis, whose English name is the Ironweed, belongs to the Natural Order Labiatae; and the various species come from the south of Europe, principally from Spain. The species under notice, S. euboea, whose most suitable position is on a very sunny, hot, well-drained slope, or the moraine, is a trailing plant, with white, woolly foliage and spikes of yellow, Labiate flowers about six inches high. They are not specially effective, yet the plant has about it some points of beauty.

S. euboea is increased by seeds or cuttings. It is hardy when given the treatment suggested above, but in districts where the winter rainfall is very heavy, some protection, such as a sheet of glass overhead, will be appreciated. *S. A.*

THE OMPHALODES.

Rivalling the Gentians in the colouring of their flowers, in fact, comparable even with the elusive Eritrichium nanum in this respect, the Omphalodes exercise the same fascination over alpine plant growers as do the Gentians and Eritrichium, and although only a few species are in cultivation, yet at least one, *i.e.*, O. Luciliae is, like several of the Gentians and certainly like the lovely Eritrichium, so difficult to grow well that success with it is no mean achievement.

On the other hand, there is the lovely little Blue-eyed Mary, O. verna, which is familiar to all as a desirable spring-flowering subject of the easiest culture, being happy no matter where it is planted, so long as afforded slight shade and a cool root-run in leafy or peaty loam, and especially suitable for the rock garden or open woodland. For O. verna is a quick-growing plant of dwarf habit, forming ever-widening mats, by means of trailing growths which root as they spread, of fresh green, heart-shaped leaves, lightened from March until the end of May with dainty sprays of rich, azure-blue, white-eyed Forget-me-not flowers. Little Blue-eyed Mary, in nature, haunts shady copses and open woodland, and is never so attractive as when naturalised in such places. And this little, unimposing Omphalodes has achieved historical fame, for it is stated to have been the favourite flower of the hapless Queen Marie Antoinette, no doubt recalling to her, during the unhappy latter part of her life, memories of pleasant childhood hours spent rambling through the copses and woodlands around her native home, where was to be found little Blue-eyed Mary. The white form of this plant cannot compare with the type, for it is in the refreshing blueness of the flowers that the chief charm of O. verna lies, although for this reason var. alba should not be deprived of a position similar to that afforded the type.

Another member of this family which is of easy culture and quite hardy is O. cappadocica, from Asia minor. Whether cappadocica is the correct name of this species or not is difficult to tell, for many authorities describe it under the name O. cornifolia, under which appellation it is also offered by many of the leading alpine plant nurserymen, while another of its synonyms is O. Witmanniana. However, despite the doubt as to its correct name, it is a worthy applicant for a place on the rock garden, where it should be planted in cool, leafy loam in a sheltered nook, there to form a compact tuft of prominently-veined leaves, surmounted during April and May, and often again in late summer or autumn, with sprays up to one foot high of lovely, comparatively large, bright gentian-blue flowers. If happily established—a state easily accomplished—O. cappadocica will produce its dainty sprays in abundance, and when so seen is an extremely attractive subject.

And then we have O. Luciliae! Difficult, indeed, is it to adequately describe the charms of this most lovely plant from the mountains of Asia Minor, and even more difficult is it to secure the full beauty of it under cultivation, for O. Luciliae, like so many of the élite among alpine plants, is notoriously a "bad doer." If it is coddled it is sure to die, or merely linger as a shadow of its beautiful self, while, if left to its own devices, it will most likely fall a victim to slugs, which have a special fancy for this and other extra choice plants. So, wherever it is grown, O. Luciliae must be watched over and guarded from its enemy, the slug, while its other enemy—winter wetness—must be counteracted by a carefully chosen position, a warm, horizontal crevice with a slightly projecting rock above to ward off the rain being, perhaps, most suitable, provided that the plant can secure plenty of soil moisture during the summer, and its roots have a free run in light, but not poor, loamy soil, containing an abundance of limestone chips and mortar-rubble. Or O. Luciliae may be planted in a gently sloping and well constructed moraine, in a sunny, but not scorched position, protection from winter wetness being secured by placing a pane of glass above it. And so, having provided it with conditions which would appear ideal, O. Luciliae might condescend to take root and, happy thought, it may even flourish and proceed to form a tuft of lovely foliage—long-stalked, slender, oval leaves, smooth, and with a bluish, waxy covering. And from among these, during early June and intermittently through the summer months, will be produced lovely spreading sprays of porcelain-blue flowers, exquisite in the clearness of their colouring, and like large, flattened Forget-me-nots, each nearly half-an-inch across.

If it is not desired to commit this treasure to an open air existence, then it may be included in the alpine house collection, for it responds moderately well to cultivation in a pan of well drained compost, provided, of course, care is exercised in the watering of it. This latter is very important, for if, while in growth, O. Luciliae receives an insufficient supply of moisture at the roots, it will present a thin and bedraggled appearance, while equally dire will be the results of over-watering.

O. nitida (syn. O. lusitanica) is not uncommon in gardens, and although, perhaps, not so attractive as the foregoing species, is yet worthy of a place in the rock or wild garden, if space can be found for it. It is a native of Spain and Portugal, and forms large clumps of long-petioled, rich green leaves, the undersides of which are pubescent. Its small, blue flowers are produced in loose sprays, on erect stems, from about midsummer onwards. O. nitida should be planted in a fairly sheltered position, as it does not always survive in cold situations.

There are several other perennial Omphalodes which are desirable, but extremely rare and not easy to obtain, notably O. rupestris, which forms a dense, silvery-leaved tuft and has flowers, borne on delicate two-inch stems, of a delightful shade of blue. Another rarity is O. Thomsoni, from Tibet, while O. florairiensis, described as a hybrid between O. nitida and O. Luciliae which originated at M. Correvon's nursery at Floraire, Geneva, is stated to be very desirable, although whether it is now in cultivation would appear to be doubtful. There are also two species which are natives of Japan, namely, O. japonica and O. Ikumae, which would seem to be very desirable, O. japonica being, probably, better suited to English gardens than O. Ikumae, as it is more vigorous and produces more flowers.

Lastly, consideration may be afforded the charming annual species, *i.e.*, O. linifolia, popularly known as Venus's Navelwort, and at one time considerably more common in English gardens than it is to-day. It is a native of southern Europe, being particularly plentiful on the dry, stony hills of Spain and Portugal. It is hardy, and may be sown either in spring or autumn in the open ground, the resulting plants attaining a height of twelve inches or more, their erect stems, clothed with linear-lanceolate leaves, being terminated from midsummer onwards with racemes of white flowers, sometimes tinged with blue. It produces seeds freely and is a very attractive annual for a hot, dry situation. *M. W.*

ORCHID NOTES AND GLEANINGS.

TWO NEW CYPRIPEDIUMS.

Cypripedium Warden Pearl.—This finely-shaped hybrid is derived from the intercrossing of C. Moonstone (C. Lord Ossulstone × C. Mrs. F. Sander) and C. Psyche (C. niveum × C. bellatulum). The dorsal sepal is two-and-a-quarter inches broad, pure white, except for a small area at the base, which is diffused with lemon-yellow. The petals are two-and-a-quarter inches long and one inch wide, white in front, becoming delicately suffused with rosy-pink in the centre, the basal portion being tinted with lemon-yellow and lined with purple. The shapely lip is white around the broad, open margin, the remainder being heavily suffused with rosy-pink. The broad shield in front of the column is white, with a bright yellow centre. In form and colour, this Cypripedium has many of the characteristics of C. A. J. H. Smith, and is a very desirable addition to this section of hybrids.

Cypripedium Warden Pet.—This, another desirable addition to the C. niveum section of hybrids, is the result of crossing C. Virgo (C. Godefroyae × C. Psyche) and C. Circe (C. Tura × C. Zampa). The dorsal sepal is one-and-a-half inch broad, white, with a slight suffusion of rosy-pink on the basal half. The petals are two-and-a-half inches long, very flat, and about an inch wide, white, lined and spotted with bright rosy-pink. The lip is very much like that of C. niveum, white, heavily suffused with rosy-purple.

Both these hybrids have been raised and recently flowered in the collection of Clive Cookson, Esq., Nether Warden, Hexham (gr. Mr. W. J. Stables), where the C. niveum section of hybrid Cypripediums is well and extensively cultivated. *H. J. C.*

DENDROBIUM DELICATUM.

The Australian Dendrobium delicatum (Fig. 89) is believed to be a natural hybrid between D. Kingianum and D. speciosum var. Hillii. The flowers are white, with the exception of a number of minute, almost imperceptible, brownish-purple spots on the lip; the racemes are a foot or more in length, bearing from twenty to thirty flowers. These racemes spring from the axils of the leaves at the apical portion of the pseudo-bulbs, sometimes two or three appearing from one pseudo-bulb, and even on pseudo-bulbs two or three years old.

Although not a showy Orchid, it is very pleasing and attractive as a large and well-flowered specimen. The plant exhibited at the R.H.S. Hall, on February 12, this year, was bought as D. Kingianum var. album, at Mr. Smee's sale on May 5, 1902, and grown at Rosslyn, Stamford Hill, London, for twenty four years; although it produced flower spikes freely at Stamford Hill, many of the buds and flowers were lost owing to the adverse atmospheric conditions. The plant was purchased for S. G. Brown, Esq., at the Rosslyn sale, and has apparently appreciated the clearer and purer air of Shepperton, as this season it produced twenty-four racemes and developed its flowers perfectly, which is further proof that this Orchid, like many others, is a lover of light and pure atmosphere.

Dendrobium delicatum should be grown in a light position at the warmest end of the cool intermediate house with such plants as Odontoglossum grande, Lycastes, Maxillarias, Sobralias and Miltonias, and given as much sunlight as is consistent with the health of the other inmates of the house. After flowering, the plant has a period of rest, and during that time should be kept somewhat drier at the roots, applying sufficient water only to prevent the pseudo-bulbs from shrivelling.

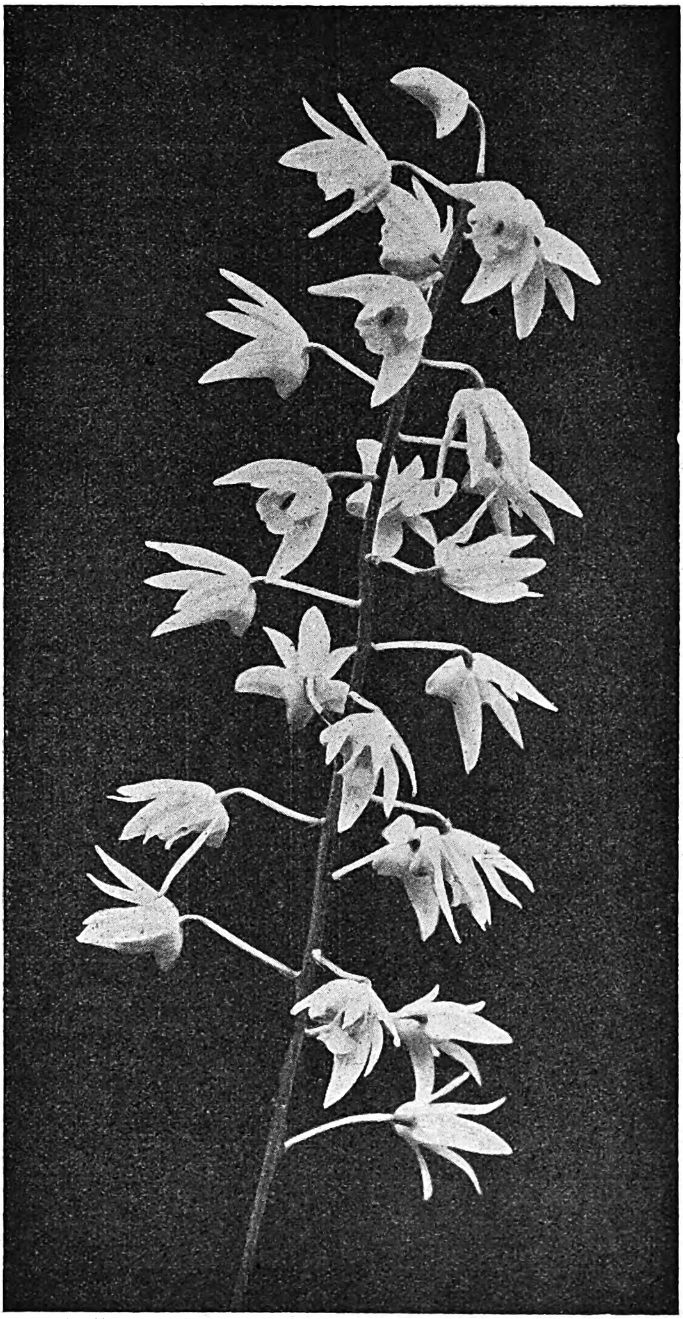

FIG. 89.—DENDROBIUM DELICATUM.

So soon as growth commences, any necessary repotting should be done, turning the plant out of the pot carefully, removing all impoverished material, and cutting away all dead and decaying roots. The new pot should be of sufficient size to allow the plant to remain for two or three years without disturbance; half fill the pot with crocks, place the plant level with the rim, and work the compost carefully among the roots. Pot moderately firmly, using two-thirds Osmunda or A.1. fibre and one-third Sphagnum-moss cut moderately short, mixing the whole well together. If the roots and material are in good condition, the plant may be potted without any disturbance. After repotting, supply water rather sparingly until the roots have permeated the new material, and spray the plants overhead on bright days. When the new growths are well advanced and near completion, afford water to the roots freely, and when the plant is developing its buds and flowers, never allow it to become dry. Keep this Orchid free from thrips and scale by fumigating the house at intervals and sponging and cleansing the growths with a suitable insecticide. *F. W. Thurgood, Brownlands Gardens, Shepperton.*

INDOOR PLANTS.

CALLIANDRA HAEMATOCEPHALA.

About a year ago, I received a rooted cutting under the above name from Mr. Free, horticulturist at the Brooklyn Botanic Garden, and, being unacquainted with the species, I endeavoured to obtain information concerning it, but could find no mention of this plant in any reference book at my disposal, and so was forced to the conclusion that Calliandra haematocephala is not common in cultivation.

It succeeds well under stove-house conditions and is of rather lax, shrubby habit; my plant attained a height of approximately two-and-a-half feet last season. The alternate leaves are bipinnate, each pinna consisting of seven to ten pairs of pinnules. The terminal leaflets are larger than those at the base of the pinnae and average, on a well-developed leaf, about two inches in length by three-quarters-of-an-inch in breadth; each has two prominent nerves. The leaves and younger stems are dark green and pubescent, while the more mature stems assume a brownish hue.

Shortly after Christmas the inflorescences (which had been developing for a considerable time) commenced to expand, the flowers remaining in good condition for two or three days and following each other in acropetalous fashion. The peduncles are axillary and about two-and-a-half inches in length, and at their terminations the unopened flower buds aggregate and bear a striking resemblance to an unripe Blackberry, being dull red in colour. When they open, the petals of the small flowers are pink, but it is the bunch of protruding stamens and styles which forms the showy part of the flower. These are bright crimson and each stamen carries a black anther; together, the flowers form a hemispherical head of bloom about four inches in diameter and some two-and-a-quarter inches in depth, like a small powder-puff in general appearance.

The genus Calliandra is included in Leguminosae, and consists of some one-hundred-and-twenty species, distributed throughout the tropics. Bailey, in his *Cyclopedia of Horticulture*, describes four species and mentions four others. The Brazilian C. Tweedyi is cultivated in choice collections of stove plants. *T. H. Everett, New York, U.S.A.*

BULB GARDEN.

TRICYRTIS.

It requires some courage to write much in favour of the Tricyrtis, the Toad-Lily of Japan, in face of what the late Reginald Farrer stated of the genus in his inimitable work, *The English Rock Garden, i.e.*, that they "emit large and evil flowers." Others are more complimentary, and one writer of reliable standard works calls the various species "distinct and ornamental plants." It is not easy to follow the golden mean between the two, but certainly the plants are so distinct that they are well worth trying, while their intrinsic attractions are, at least, sufficient to give them a claim for inclusion in a good collection of hardy flowers. This remark is made with some reservation, as authorities generally agree in pointing out that they are often so late in flowering that the frost overtakes them before the blooms open, and, in consequence, they recommend that they should be grown in a pit or cool greenhouse. This late-flowering habit is a great drawback in cold districts, but in good seasons, and if the Tricyrtis are planted in a warm position, even the lapse of a season or two should not warrant their exclusion. The treatment afforded them is usually that of Trilliums, although the latter prefer a little shade, which is inadvisable in the case of Tricyrtis, as it would retard their flowering. I have always grown those I have tried in a light soil and a warm, sunny position, giving them water when they seemed to require it, although they are woodland plants in their native haunts in Japan.

The name Tricyrtis is derived from *treis*, three, and *kurtos*, convex, on account of the three outer segments of the perianth having sac-like bases. The genus belongs to the Natural Order Liliaceae and the Tribe Uvulariae. They are mostly natives of Japan, but one of the species enumerated in works of reference, T. pilosa, comes from China, and another, T. pilosa, from Sikkim. So far as I can ascertain, the species in commerce are T. hirta, from Japan; T. macropoda, also from Japan; and T. pilosa, already mentioned. Farrer gave a rather alluring description of another, the Japanese T. Hototogisu, meaning the nightingale of the woodlands." This species has six-inch stems and sprays of flowers, but I do not think it is on the market. All the others are of much the same appearance, but the best of all, because of its earlier flowering habit, as Farrer stated, is T. macropoda.

If grown in good soil, T. hirta will attain a height of from two to four feet; it has alternate, lance-shaped, green leaves, corrugated and hairy. The flowers are produced on the ends of shoots and in the axils of the upper leaves; they are white or pinkish, spotted with violet or purple. The flowering period of this species is from August to October, nominally, but is generally later.

T. macropoda grows from three to four feet high, and has pointed, oblong leaves four or five inches long, downy on the under surface and smooth above. The flowers are of a pale purple or pink hue, spotted with deep purple. According to some authorities they are greenish-yellow, but those specimens I have grown have had pale purple grounds. This species was figured in the *Botanical Magazine*, t. 6,544.

T. pilosa hails from the Himalayas. It grows to from two to four feet high, and has hairy, stem-clasping leaves four to six inches long, the flowers being dull and white in colour, with large, dark purple spots. It was figured in the *Botanical Magazine*, t. 4,955.

MERENDERA CAUCASICA.

The Merenderas, small plants with twisted tubers or bulbs, are closely allied to the Bulbocodiums and Colchicums; the name Merendera is that applied in Spain to the Colchicum. Of the few recognised species, so far as I am aware only three are in commerce, these being M. Bulbocodium, M. caucasica and one named M. sobolifera. Few are grown in British gardens, M. Bulbocodium, a Pyrenean species with pink flowers produced about August, being the best known. For some time, M. caucasica, said to be synonymous with Bulbocodium trigynum, and a native of the Caucasus, has been unobtainable. Last autumn, however, Messrs. G. C. van Tubergen, junr., Ltd., offered bulbs of this species, and a group of this flower is now in bloom (February 9), the first flower opening about a week ago. This Merendera has small, globular flowers, white, tinged with violet or lilac, and, although not showy, is very pleasing and welcome so early in the year. Authorities differ regarding its flowering time, and it is probably earlier this spring than it may be in future, as one frequently finds that bulbs which have been dried off are earlier the first season. In any case, M. caucasica will be welcome at any time. April and May are given as its usual flowering season, but I think that is rather late. The narrow leaves come after the flowers begin to open.

A sandy, rather moist soil is recommended for it, but in order to keep the flowers free from defilement by splashes of soil in wet weather, I have surfaced the bed with chips. M. caucasica is figured in the *Botanical Magazine*, t. 3,690.

GALANTHUS NIVALIS VAR. VIRESCENS.

Galanthus nivalis virescens is a curious variety of the common Snowdrop, G. nivalis. It was originally distributed from the Vienna Botanic Garden, Professor Fenzl, the late Director there, having grown it, and from him Max Leichtlin, of Baden-Baden, bought two bulbs and sent one to Mr. James Allen, of Shepton Mallet, and thus its cultivation in British gardens was commenced. It is a late-flowering variety of B. nivalis, and is noteworthy from the presence of so much green on the flower. The inner segments are almost entirely green, and the outer ones are faintly lined or flushed with green, except at and near the edges. G. n. var. virescens is prettier than would be supposed, and those who have grown it once are sorry to lose it. *S. Arnott.*

HARDY FLOWER BORDER.

CAMPANULA LACTIFLORA.

The specific name of this Campanula would lead us to expect milky-white flowers, but the garden varieties usually grown are in shades of soft blue, with a mauve basis. This Campanula has been described as one of the best half-dozen hardy perennials, and a well grown clump with a dozen six-foot stems, skilfully arranged and supported, may well be the most beautiful object in a herbaceous border in its season, while its sweet scent is by no means the least of its attractions. But it is not without its disadvantages, one being the difficulty of either moving or propagating it. An established clump has very long, fleshy roots, so that it is a risky thing to lift it with the intention of dividing it, while shoots taken off the stock in spring are difficult to strike. One way in which new plants may be obtained is to get a piece from the side of the clump, with a piece of root attached—and this is not easy—and plant it at once where it is intended to grow, when it will make a moderate flowering plant in two years. In some soils and conditions C. lactiflora produces seeds freely, but never with me. Seedlings vary much in colour and not all are equally desirable.

This plant needs careful tying up and the sheaf fashion does not meet the case at all. Its growths are not only tall, but succulent, so that it needs tying almost to the tips of the stems, and even then the short sprays or laterals upon which nearly all the flowers are produced are so brittle that they sometimes give way in a heavy rain and make the whole plant a wreck.

C. lactiflora requires a deep, moist soil to produce its full effect, while the flowers last better if in partial shade. When putting in new plants it is sometimes necessary to make holes nearly two feet deep to allow the roots to go straight down their full length and have something beyond to start upon. *A. P.*

WOODLAND GARDEN.

TRIENTALIS EUROPAEA.

There is no more dainty woodland plant than Trientalis europaea, which is a native not only of Europe, including parts of Scotland and England, but of a considerable portion of the northern hemisphere. Commonly known as the Chickweed Wintergreen, this comely little plant is a member of the Primulaceae. In some gardens it grows and spreads abundantly, even in grass, but in others it is not so easily satisfied. Its natural desire appears to lean towards partly-shaded spots and a cool, light vegetable soil. Accommodated thus, it will produce, in spring, a single, slender stem bearing a few small leaves, and terminating in a whorl of six or seven much larger ones, suggesting those of Herb Paris. Then, from the centre of this leafy rosette arise, in June, from one to four hair-like pedicels of a pale red tint, each of which terminates in a single flower. These pretty, star-shaped blossoms, which are pearly-white, sometimes suffused with a touch of pale rose, are the last word in fragile delicacy. In their colour, their form and their poise, they have a fairy-like grace of enchanting loveliness; and the fact that their time is short, for they do not stay long, only tends to accentuate their charm.

T. europaea, I have to admit, has not been an unqualified success here. It has not shown any inclination to naturalise, and does not display that heartiness—if one can apply that word to such an elf—which it does in some gardens. However, a generous friend having sent me a slab of turf full of the precious thing, I can look forward with buoyant hopes. *N. Wales.*

TREES AND SHRUBS.

THE PROPAGATION OF ARBUTUS.

The propagation of Arbutus from seeds is the best method to follow with the true species; and also, to a certain extent, with Arbutus andrachnoides (hybrida), for although in all cases the original type plant will not be exactly reproduced, some interesting varietal forms may be secured. Seeds of the European species are obtainable from continental sources, while seeds of Arbutus Menziesii may be purchased from American seedsmen, although young plants of this species have been raised successfully from seeds produced in Britain.

The cleaning of seeds from the "Strawberries" of Arbutus Unedo, A. Andrachne and A. andrachnoides is a very tedious business, but one that repays care; it is, perhaps, best done by just picking out the seeds from the sticky flesh and rubbing them in dry sand; this will effectively remove most of the mucilaginous coating, and the seeds may then be sown in pots or pans in an ordinary mixture of loam, leaf-soil and sand, with or without the addition of peat.

The seeds are comparatively small and need just a light covering of finely sifted soil. After sowing, which is best done in January and February, the seed-pans should be placed in a greenhouse having a temperature not lower than 45°, where the seeds will usually germinate in from four to six weeks. When large enough to handle, the seedlings should be potted singly into small pots. From the very earliest stages the young plants will need every care, as all the Arbutuses are notorious for their resentment to root disturbance. Potting on as required and then planting the young plants into their permanent positions is recommended in preference to planting out in a nursery bed, as even young plants transplant badly.

It will be found that the seedling plants, in the main, will grow away very vigorously and attain a height of four feet in four years. One precaution should be taken and that is to securely stake the young plants for the first few years as, being top-heavy, they are easily blown over and broken off at the "collar" by the wind.

For some obscure reason, seedling plants of Arbutus—particularly of Arbutus Menziesii—will die off very suddenly, even when they appear to be established and in good health, and have attained a height of one foot or more. Plants which, to all appearances, are quite happy and thriving one week will be dead the following week and, at present, no satisfactory reason can be advanced for this behaviour. Other plants possessing the same unfortunate peculiarity are Arctostaphylos Manzanita, Eucryphia cordifolia and, to a smaller extent, Eucryphia pinnatifolia.

The varietal forms of the common Strawberry Tree must be propagated by vegetative means; more often than not grafting is resorted to, using seedlings of Arbutus Unedo as the stock. Grafted plants, however, tend to become less tolerated than formerly, and a plant on its own roots is always more desirable. The layering of suitable branches gives quite good results, but extreme care is needed when transplanting the rooted layers.

Propagating Arbutuses by cuttings has apparently been seldom tried, and the following results may be of some value as suggestions to those who like to raise their own plants. Cuttings of such varietal forms as Milleri, rubra, quercifolia, and integerrima will root quite successfully if made about three inches long, of the current year's wood, taken from October until January, selecting the short, side branches near the top and making them with a slight heel of older wood, or severing them at the junction of the current and previous years' growths.

The cuttings should be made carefully and inserted in pure sand in a propagating frame having a bottom temperature of about 60°, where they will produce sufficient roots in from six to ten weeks to permit of potting. Cuttings inserted on October 20, 1928, were potted up in January, 1929 (Fig. 90), and therefore have a long growing season ahead.

A plant of Arbutus Unedo raised from a cutting inserted in January, 1925, is now (January, 1929) over two-feet-six-inches high, and possesses quite a good leading branch and symmetrical appearance. A cutting of the variety quercifolia inserted at the same time has developed into a bush about two feet high. The rooted cuttings require the same careful treatment as advised for the seedlings; and, except for being a little less vigorous in growth, they exhibit every promise of forming good specimen plants. *F. P. Knight, Kew.*

BUDDLEIA ALTERNIFOLIA.

Although this shrub was introduced by the late Mr. Reginald Farrer from the mountainous regions of south-west China so recently as 1914, it has already become well-known in gardens where choice shrubs are grown. It has been a worry to botanists, as it is the only Buddleia with alternate leaves, instead of opposite ones. It was found growing on dry, sunny banks, but although it is in such positions that it produces those "waterfalls of purple beauty" which Farrer saw, it is very accommodating, as may be seen at Wisley, where it is growing by the side of the big pond. But anything like dampness and shade results in such lanky growths that it loses its character of a Weeping Willow covered with mauve blossom in May. I planted one in such a position a few years ago, and it made seven feet of growth in the second summer and produced no flowering sprays for two or three years afterwards. It will be seen that it needs a good deal of space when it grows well, and a fair average shrub might be reckoned as about seven feet in height and breadth. It is one of the worst of all shrubs to move, even when small, as it roots deeply, with almost fibreless roots. It is thus a good shrub to hold its own in dry places near trees, so long as it is not shaded too much.

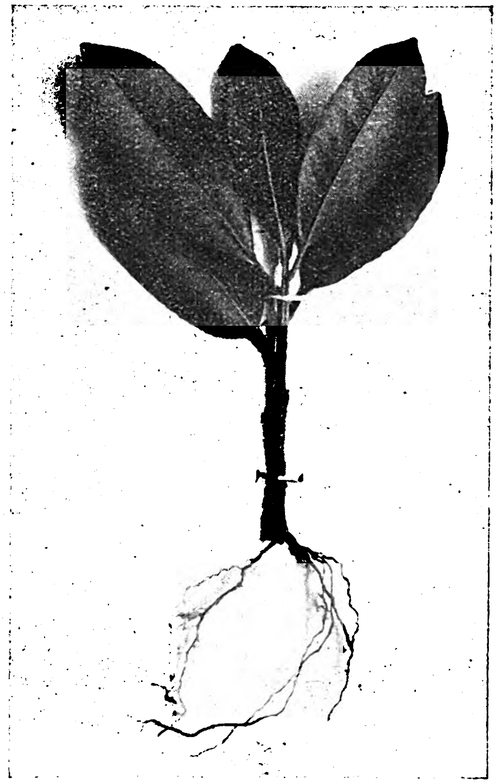

FIG. 90.—A ROOTED ARBUTUS CUTTING.

It flowers on the young growths of the previous summer, so that pruning should be done immediately after flowering, cutting out all the spent wood to encourage the growth of the long, slender shoots for flowering next year. Cuttings may be made of the half-ripened, young growths at the end of July, but are not so easy to root as those of many shrubs, the growths being thin and wiry, and the leaves lacking in substance.

A great authority considers this shrub the best for general garden purposes of all recent introductions. There is one thing against it, *i.e.*, its unsuitability for cutting, but this it shares with Buddleias in general. So far as one can ascertain, it has come through the recent severe frosts without harm. *A. Petts.*

PHYLLODOCE COERULEA.

This is usually regarded as a somewhat doubtful subject, save, perhaps, in the north, but after trying it in various parts of the garden, it has at last become fairly well established. If we cannot always give such plants the atmosphere they ask, something can be done towards the maintenance of that uniform supply of moisture which is essential by providing a retentive vegetable soil. Further, a top-dressing of chopped Sphagnum-moss will afford a taste of moorland conditions, failing which some granulated, fibrous peat-moss may be used. An old specimen of P. coerulea which had not been particularly happy elsewhere was moved nearer the water. But even here it did not show a very bright response until it got nearly smothered by a mass of Parochetus communis. This seemed to give it what it wanted, for it has developed a quite remarkable vigour and health, and has not gone back since its companion was reduced by a necessary thinning.

This little shrub, now about four inches high and nearly a foot across, is much like the rest of the genus in general appearance, but with its lowlier stature goes a blunter leafage and a harder, more stubby growth. The foliage is a medium green, the short, linear leaves being thick and glossy, with a bronzy tint at the tips in winter. The flowers, which sometimes appear so early as May, are borne singly in loose, terminal umbels of three or four blooms. The pitcher-shaped corollas, nearly one-third-of-an-inch long, are a bluish-purple, which hardly justifies the specific name. Still, the colour is an uncommon one in plants of the kind. P. coerulea possesses a special interest in being one of our rarer natives. *N. Wales.*

HOLBOELLIA LATIFOLIA.

This plant, a native of the Himalayas, introduced in 1840, is probably one among many of the good things for which garden lovers have to thank the botanic gardens. It has twining stems and handsome, evergreen, foliage, each leaf composed of three or five dark green, shining leaflets, and raises great hopes of flowers to match; but only short corymbs of small, greenish-purple flowers are produced from the axils of the leaves. The disappointed private owner would promptly discard it, as "of botanical interest only," unless attracted by the delicious scent. Even this may not be always noticeable from a few flowers in cool weather, but once a plant is established it grows rapidly, and flowers freely in a sunny position. We have proved that it is sufficiently hardy for the more favourable parts of the country.

About twenty years ago, a specimen was planted against a south wall, and, as it grew rampantly, it was accommodated with a trellis above it; this proving insufficient, it was next directed by a few strong wires into the boughs of some tall Spruce trees. The plant has now taken complete possession of the trees, almost reaching their tops—a height of sixty to seventy feet; its fragrance, on a warm day in early summer, scents that part of the garden.

According to Mr. W. J. Bean, the fruits are sausage-shaped, two to three inches long, and are eaten by the natives in its country of origin. To secure fruits in this country, however, the flowers should be pollenated by hand. So far as I know, none have been borne by the plant at Nymans.

Cultivation is simple. Small or stunted plants should be grown on in a cool house until healthy and vigorous, and planted outside in April. Good drainage is essential. Where it has space to extend, little or no pruning is required. *J. Comber, Nymans Gardens, Handcross, Sussex.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

DAVIDIA INVOLUCRATA.

ALTHOUGH the precise number is not known, it is a matter of history that a few rooted cuttings of the first plant of Davidia involucrata raised in Europe in 1899, were sent to this country in the opening years of the century by Mons. Maurice de Vilmorin, from Les Barres. It was stated at the time that there were five or six of these French-raised trees here, and although they had a year or two's start of those raised at Coombe Wood from the seeds sent there by E. H. Wilson in 1900, they do not seem to have reached the flowering stage before the latter. There is nothing remarkable in that, however, because this Davidia is curiously capricious in its flowering, and in some instances seems to make growth at the expense of flowers; the writer has two trees in mind, in different parts of the country, which, to his knowledge, are each twenty years old, yet have not shown any sign of a flower. On the other hand, trees junior to them and much smaller have flowered in several seasons and in many places. The point may, perhaps, turn to some extent on the treatment of the tree, and those which, following the hint originally given to so many by Sir Frederick Moore about fifteen years ago, are kept to a clean stem and a bushy top, seem to flower more often and more profusely than those which grow as they please.

It has not been possible to trace more than three of the French-raised trees, and of these the first to flower seems to have been that in the Himalayan House at Kew. That specimen was received from Les Barres as a rooted cutting in 1901, and at the beginning of May, 1913, it put forth one flower.[*] Twelve months later it bore seven flowers and, subsequently, two fruits. In 1915 it was thirty feet high and carried two hundred flowers. A photograph of it was reproduced in *The Gardeners' Chronicle* soon afterwards.[†] As those interested in these things will remember, this tree flourished to such purpose that it eventually grew so tall that it had either to be let out through the roof of the Himalayan House or suffer removal. Having no option in the matter, the authorities at Kew decided to attempt the transplantation of the tree, and might possibly have achieved their purpose successfully, but for some slight disparity between the size of the ball of the tree and of the doorway through which it had to pass on its way out of the house. As no compromise seemed possible at that time of war-depleted staffs, the necessary adjustment had to be made at the expense of the ball, and if the tree did not long survive the ordeal, it may be doubted if it would have suffered the move in any case. The particular specimen was even then probably taller than any out-of door Davidia is now, and as it was touching the glass of the roof of the house, it was not possible to enjoy the effect of the flowers unless one stood as far off as possible—at the northern entrance door, in fact.

The first recorded instance of the flowering of this Davidia here was in 1911, when a Wilson seedling flowered at Coombe Wood nursery, and considering that Messrs. James Veitch and Sons had commissioned Wilson to journey to western China in search of seeds, it was naturally regarded as an event.

The first of Wilson's seedlings of D. involucrata to flower in a private garden seems to have been that at Aldwick Manor, one of three which Mr. W. H. B. Fletcher planted in 1902, which showed two flowers in 1912.[*] The Aldwick tree, which is the glabrous-leaved form of the type, is as shapely a specimen as anyone could wish to see, and exhibits the suckering habit which is not common to all specimens of D. involucrata. In the following year, Mr. J. A. Christie, of Framingham Pigot, wrote that the tree in his garden was flowering for the first time and had twenty-one blooms on it.[†]

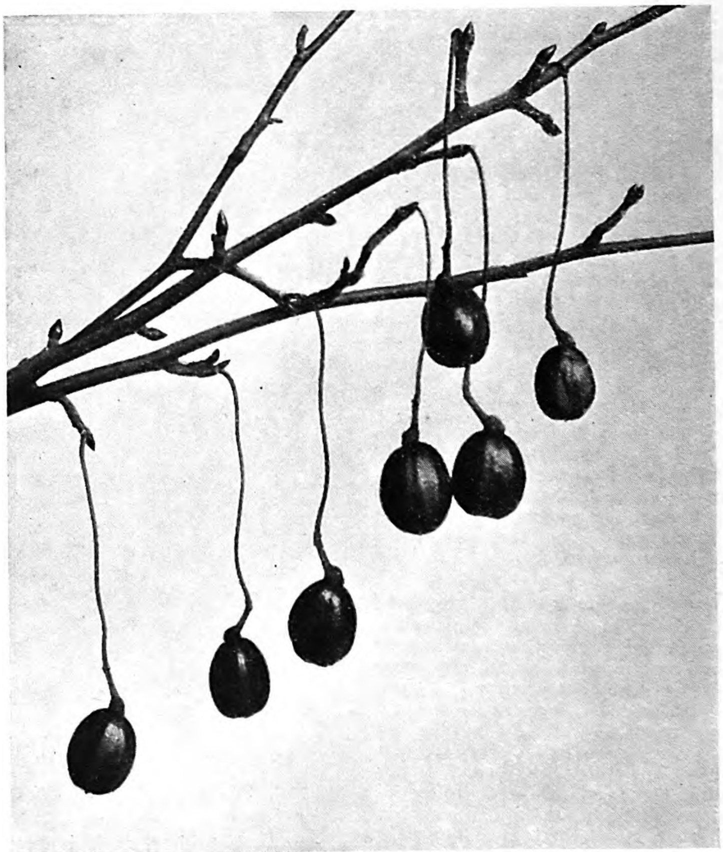

FIG. 91.—FRUITS OF DAVIDIA INVOLUCRATA.

Although a tree of D. involucrata in flower is worth a long journey to see, it is no longer the rare event it was fifteen years ago; the flowering seems to depend a good deal on the weather of the late spring, but whether a cold winter has an inspiring effect on this tree, as it undoubtedly seems to have on some other flowering trees, is not clear. It flowered very well in many places in the hot season of 1921, and only fairly well last year; but then the weather of the late spring of 1928 was exceptionally trying to all vegetation. Although it must have been of comparatively recent date, and probably not before 1915, there does not seem to be any published record of the first fruiting of the tree here. It occurred, however, before a fruiting spray of D. Vilmoriniana was shown at Vincent Square in August, 1914, by the Director of Kew Gardens. A tree in fruit bears a superficial resemblance to a Walnut, and the resemblance is increased by the fact that the fruits (Fig. 91) hang on long after the leaves have fallen.

Although D. involucrata is undoubtedly hardy, so far as winter cold is concerned, gardeners have had to modify their views on the general hardiness of the tree to which expression was given in the earlier editions of *Trees and Shrubs Hardy in the British Isles*. In that invaluable work the view was expressed that, in so far as it was possible to judge at the time (1914), the tree was absolutely hardy: "It starts into growth late, and ripens its shoots in autumn up to the tip—two valuable attributes in regard to hardiness." That view held good until the spring of 1926, when Davidias had a bad time generally. Specimens at Headfort, in Co. Meath, were stripped of their leaves by a frost in early May, and later in the month, the flowers on some trees at Kew were entirely spoiled by the same agency. At the end of April of the following year, the writer noticed that the leaves of a specimen labelled D. Vilmoriniana near King William's Temple at Kew, were on the ground. The frost at the time was no more than a few degrees, but it occurred on three or four successive nights, and came after a warm spell. The frost culminated in a black May Day, and caused wholesale damage, even to trees which we are accustomed to regard as quite hardy. The illustration (Fig. 92) is from a photograph of the well-balanced tree in the garden at Aldwick Manor and was taken by Mr. Fletcher several years ago. As already stated, this particular tree was among the first to flower in England. When Mr. Fletcher measured it on the 15th of last month, he found it was twenty-six feet high and had a thirty-two-and-a-half feet span. The girth at three feet was twenty-eight inches, and an inch or two less at four feet. From ground level to the first branch was seven feet. The notion, which seems to have originated in France, that the fruits of Davidia are edible when bletted like a Medlar, needs verification. *A. Grove.*

LUDGVAN RECTORY.

The recent flood of new Chinese plants which has swamped many gardens and still threatens to submerge us all beneath an apparently inexhaustible deluge of Rhododendrons and rock plants, should not blind us to the fact that, before the Oriental dam burst, other countries had already contributed their quota. So breathless are we at the moment, striving to cope with the Celestial flood, we seem to have forgotten—if we ever knew—that a wealth of first-class plants from the Antipodes has long been established in this country, many of them now being stout bushes or even tall trees. In a few years it may be possible to compare the parvenus of the east with the aristocracy of the south on something like equal terms, when it will be found that the latter lose nothing by the test; in the meantime let us endeavour to keep our sense of proportion, and not entirely lose our heads over the latest débutante! After all, New Zealand, British Columbia and the Andes have long since enriched our gardens, and the interior of China has remained the last storehouse of floral treasures only because temperate Asia has always been the most difficult region to explore.

Unfortunately, the south temperate flora is, in this country, hardy in only a few favoured spots, and although some of the New Zealand and Chilian trees have been known for nearly a century, most of them are quite rare in English gardens.

There is, however, hidden away in the *ultima Thule* of the west country, a small garden of exquisite beauty, where trees and shrubs from the southern hemisphere grow with a will; a garden which fulfils the ideal of a garden which is not a mere museum, so that we may walk round it three times, and see it with new eyes each time. We find that in the wild, of course, noting new plants as many times as you retrace your steps; but in the wild the terrible confusion is too near the surface not to appal even the most superficial observer.

For thirty-five years the Rev. A. T. Boscawen, V.M.H., has cultivated and cared for these plants, every one of which he has himself raised from seeds or from cuttings, and put out with his own hands; and for thirty-five years, under his care, this Cornish garden has increased in beauty of colour and beauty of form, every plant being welded harmoniously into the whole, as though on it alone rested the success or failure of the garden; as, of course, it did!

Ludgvan faces south and west, on a shelf of rising ground a mile from the Atlantic. Although not entirely frost free, its chief enemy is the south-west wind, from which so many of our soft, west coast districts suffer. Nevertheless, the climate is such that many trees and shrubs never seen in the London district, except under glass, are perfectly hardy there; and the Rev. A. T. Boscawen, who has done horticulture invaluable service, can now contemplate a finished and romantic garden with pardonable pride; finished so far as any garden can be finished, although it continues to grow; romantic, because it suggests a tropical oasis springing up in an otherwise rather bare land.

Ludgvan, then, may be regarded as the home of south-temperate plants, including many of the earlier introductions, but including also many which have never been flowered in this country.

No attempt has been made to cut the garden up into departments. The lawn slopes down between belts of trees with outlying Palms striding on to the grass, and here and there a tall shrub marooned. Winding paths thread the massed vegetation, and suddenly the visitor comes on a bulge of rock work overflowing with wide waves of a precious creeper, or descends into a grotto whose angular slopes are plated with metallic foliage. For it is a remarkable feature of this garden, devoted to trees and shrubs, that the very rocks are covered with clinging carpets of woody plants. Among these one notes:—Ficus repens, smallest of Figs; Rubus parvus, a Raspberry which hid itself in New Zealand and has tried to hide its identity ever since; and the Chinese Gaultheria trichophylla, which, although not wonderful in flower, breaks out all over into clouds of large blue berries in the autumn. Others are Coriaria thymifolia, Cyathodes (Styphelia) ricifolia, Styphelia robusta and Ficus procumbens. A few of the rock plants, however, erupt into violent colour, and the large, sessile discs of Heeria elegans, for example, daub a whole rock face with vivid magenta.

A group of rare plants—rare, or even unique in this country, at any rate—grow beneath the shadow of a wall. On the wall itself Epacris miniata dangles its dancing clusters of Venetian-red, glassy tubes (the rim frosted white); this is a much better way of growing so elegant a plant than all scrabbled up on the rock garden, when the leaves completely hide the flowers. There is also E. microphylla. Those who know Pentapterygium serpens only as a greenhouse plant would be astonished to see it here, six feet high, its numerous, arching sprays fringed with pointed flowers. Knightia excelsa, twenty feet high, far overtops the wall, but in New Zealand it attains a hundred feet; its first flowering in this country is eagerly looked forward to. A low bush of Bauera rubioides, from Australia, dangles a wealth of rosy-purple, shell-like flowers, and against the wall the twisted, white-enamel corollas of Styphelia tubiflora glimmer in starry figures over a huge, crouching bush of Philesia buxifolia.

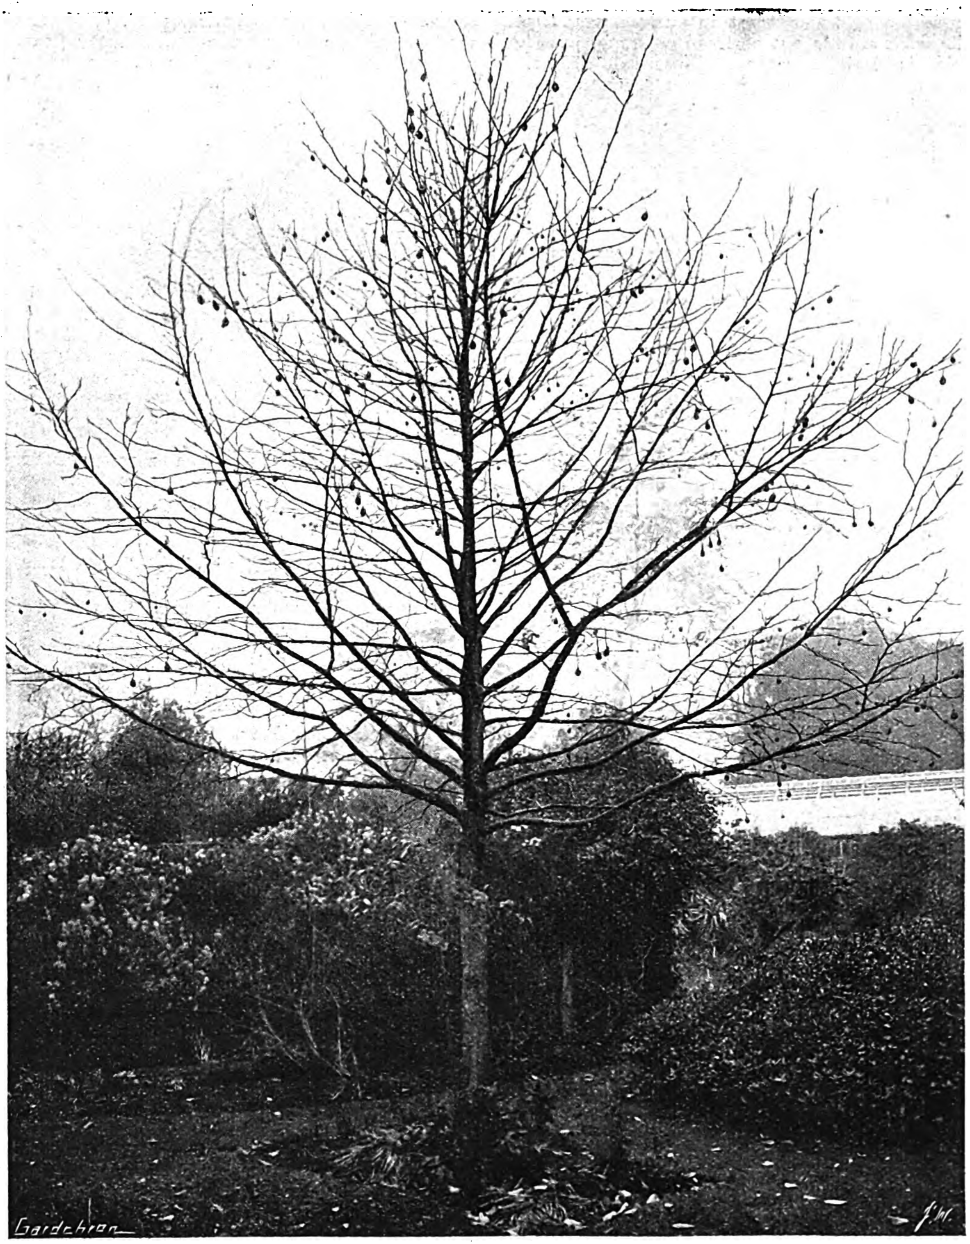

FIG. 92.—DAVIDIA INVOLUCRATA.

A fruiting specimen of the glaucous-leaved form at Aldwick Manor, Sussex. Planted November, 1902.

The house walls are entirely covered with climbing plants, one of the finest being Passiflora mollissima, whose great, pinkish flowers hang clear of the foliage. Mutisia Clematis, which has grown up stoutly at the angle, has embraced two sides in a curtain of silver from among which, on one side, ripple out emerald-green splashes of Ruscus (syn. Semele) androgynus, in arched waves. On the other flank, an orange-flowered Bomaria skirmishes, and Fuchsia cordifolia has the remaining space allotted to it.

A fine variety of Phormium tenax is grown, the leaves being twice the width of the type; two great clumps of this handsome plant flank the lawn. Near-by, a regular rocket of Yucca bursts into a cloud of cream stars, which hang over a mound awash in an eddy of dwarf Veronicas, such as V. Willcoxii, V. elliptica glauca and V. Astonii.

August-flowering trees are valuable, particularly in the west country. A magnificent bush of Clethra arborea, is twenty feet high and as much through; and there are two large, columnar trees of Hoheria populnea; several slender pillars of Eucryphia cordata; the quaint-leafed Myrtus bullata, Plagianthus (syn. Gaya) Lyallii, and a bulky bush of Olearia oleifolia, all bloom during the eighth month; and much colour is added by the shrill gamboge of Calceolaria integrifolia, the scarlet of Fuchsia triphylla, Gladioli, Oenotheras and various Heaths. Among these last are double Ling, double Bell Heather, and the fine form of Erica vagans discovered by Mr. P. D. Williams, *i.e.*, var. kevernensis.

But flower colour is only one of many chords which go to make up the harmony of Ludgvan; beauty of foliage is another. There are numbers of handsome foliage trees, many of them upwards of thirty feet high; and somehow their blues and greens and reds and silvers have been made to combine or to contrast in such a way that, while each stands out as from a frame, yet the whole is knit together. Beautiful are the Pittosporums, P. tenuifolium and P. eugenioides; others include P. Dallii, P. Kirkii and P. Buchanani. Nothofagus fusca, thirty feet high, and smaller plants of N. Dombeyi and N. Cunninghami, all have both colour and quality; and such as Podocarpus Totara, forty feet high, Aralia japonica, Pseudopanax crassifolium, P. arborea, the 'Ake,' (Dodonaea viscosa), in fruit, and a huge bush of Eupatorium Weinmannianum, in full bloom, make a very agreeable impression.

Many Olearias of large size are to be seen here, and as those flower late, they are of peculiar value, although so handsome is their foliage that they are worth their place at any season. The original plant of O. semidentata, from which nearly every specimen in the country has sprung, is here, and a fine bush of O. oleifolia, fifteen feet high, is massed with flowers in August. The large, flannelly leaves of O. insignis are most attractive, and rare species include O. Colensoi, O. furfuracea, O. Traversii, O. nitida and O. macrodonta. There is a dwarf form of this last, called O. macrodonta var. minor, with tiny leaves, growing but two feet high, at home in the rock garden. But the most interesting species of all is O. lacunosa, perhaps the only specimen in the country, certainly the biggest, although it is but three feet high, and has never yet flowered. It has long, narrow leaves, glabrous above, but covered below with ferruginous fluff, suggesting some breed of Rhododendron, and quite unlike those of any other Olearia.

For sheer brilliance of colour there is probably nothing to compare with the 'Ratas' (Metrosideros) of New Zealand. Flame Trees, they are called, and deserve to be. Imagine a big forest tree alight from top to bottom with blazing scarlet flowers—even the Gold Mohur pales beside the Australian Flame Tree. At Ludgvan, several species are grown, some of them reaching thirty feet. Metrosideros lucida, the Mountain Rata, has charming foliage; others are M. robusta, M. tomentosa, which is the Christmas Tree of Auckland, and the scrambling M. diffusa, which has not yet flowered.

The exotic appearance of this amazing garden has already been remarked upon. On every hand the visitor is greeted by Palms, such as Phoenix canariensis and Chamaerops Fortunei; tall Dragon Trees, such as Cordyline indivisa, or the squat C. Banksii; and Tree Ferns, chiefly Dicksonia antarctica, aloof, or thrusting themselves up through the tiers of coloured trees and bushes. But who would ever have expected to see a Mangrove growing in an English garden! Griselinia littoralis, a tree thirty to forty feet high which comes from New Zealand, is no less; and G. lucida, which in its native island is usually epiphytic, growing like certain Malayan species of Ficus, is much the same size, and is an invaluable wind-break.

The Wattles comprise a vast number of species, graceful both in flower and foliage; at Ludgvan they help to leaven the dense boscage with their fairy freshness. They include Acacia dealbata the Silver Wattle, A. Baileyana, A. melanoxylon, A. armata and A. retinoides.

To beat back the 'sou'-westers,' a wall of Pinus insignis has been planted, and an almost continuous barricade of trees surrounds the garden; but wind or no wind, one glimpse of the sea is permitted through a green glade, with a fair view of St. Michael's Mount swelling like a gigantic bubble from the restless ocean. The ground slants away steeply here, with a pile of rock in the foreground, over which the queer Restio subverticillatus waves its grass-like plumes.

Brachyglottis repanda is a large and handsome tree, with remarkable leaves; and the New Zealand Red Pine, Dacrydium cupressinum, although only twelve feet high, is a handsome stripling. Corokia buddleoides, Leptospermum scoparium var. Chapmannii, Cytisus fragrans, Osmanthus armatus, Ilex insignis, Callistemon floribunda, Elaeocarpus dentatus, Hakea suaveolens, and the white-flowered H. elliptica, Beaufortia decussata, Weinmannia trichosperma and W. sylvicola are other interesting plants.

Hedges of Escallonias and Fuchsias overshadow the paths; among the latter are F. serratifolia, and the tree species, F. excorticata, while over one of the rock hummocks flows a mass of the dainty, creeping F. procumbens, embroidered with coral-red fruits. So thickly do these rock plants grow that it is exceptional to see any rock exposed; and in addition to the species mentioned one notices Helichrysum Bidwillii, Phyllocladus alpinus, the 'Celery Pine,' and the South African Diosma (Adenandra) uniflora and D. gracilis.

Perhaps the biggest trees in the garden are the various species of Eucalyptus, which grow very fast. Although the stringy bark which flutters from their trunks gives them a somewhat untidy appearance, they are fine trees, and can withstand wind. Eucalyptus Globulus, scarcely thirty years old, is already a hundred feet high! E. pulchellus is fifty feet; and E. cordata, which has the bluest leaves of any, is thirty feet. Other species are E. ficifolia and E. coccifera.

Clethra arborea has been mentioned, and there is also C. alnifolia; while besides several plants of the two common Eucryphias, E. cordata and E. pinnatifolia, there are specimens of the much rarer E. Moorei and the charming E. Billardieri. The Myrtles include Myrtus Ralphii and M. obcordata. Gordonia anomala is perfectly hardy, as are Candollea cuneiformis, Nandina domestica, Aristotelia racemosa and Melicytus ramiflorus, the two latter growing thirty feet high. In places, the wealth of plants recalls the jungle, as where Sophora tetraptera and Cotoneaster horizontalis have become bound up with the long, Reed-like stems of the climbing Rubus australis. Those who labour under the delusion that all our finest introductions came from the east, should correct this view by studying the southern flora, as grown at Ludgvan! *K. W.*

NOTES FROM EDINBURGH.

It is too soon to estimate how much damage has been done by the recent frost, for although a burnt trail has been left, it may be that some plants, trees or shrubs which have had their leaves scorched, may not suffer any after effects. It is to be regretted, however, that a few have been damaged so severely as to be beyond recovery or, at least, they will carry permanent disfigurement. These are in the minority, but must be counted in the yearly casualty list. In some instances, trees such as the Sweet Chestnut (Castanea sativa) have had their bark and wood split open by the action of frost. Some of the perpendicular frost cracks or rents are large enough to admit of one's finger. Erica australis, too, is another unfortunate sufferer, as many plants of this species have had their bark entirely peeled off, which gives the plants the appearance of attack from rabbits. Others, for example Osmanthus Fortunei, have escaped with a severe scorching of the leaves and branch tips. Fortunately, there were few shrubs or plants in flower during the severe cold spell, but of tho few, nearly all of them suffered more or less damage.

Rhododendron moupinense was denuded of its beautiful white flowers during the first few hours of frost. The precocious R. mucronulatum arrayed in its soft-pink-coloured flowers and, to some extent sheltered by surrounding trees, despised the vagaries of the weather at first, but had to yield to the ever falling temperature; the transformation which took place in so short a time from a thing of beauty to a bundle of leafless and flowerless sticks was amazing. The flowers of R. parvifolium also suffered and, likewise, its companion Daphne Mezereum lost what flowers it had. Even Daphne Blagayana, close to the ground, had its first buds scarred and only escaped complete disaster by having its bud-scales intact. The beautiful Viburnum grandiflorum, claiming rank with the very early flowering shrubs, had no chance whatever; the delicate pink trusses of flowers succumbed after two nights' frost. Near-by, however, in a similar aspect, Hamamelis japonica var. arborea withstood the test. As usual, its golden mantle of yellow flowers seems to defy all frosts.

In the rock garden, plants of Primula Winteri under their glass protection looked very sickly after three days of frost. Many fully-opened flowers at the outside edges were nipped, but the remainder, so soon as the thaw set in, returned to normal, and will produce an abundance of good blooms during the present mild weather. The peeping buds of Scilla amoena and Muscari alpinum var. praecox are to be admired in corners in the shelter of the overhanging rocks. They will unfold their bright blue flowers in a few days, adding their little bit of colour and brightness during the remaining quiescent period. Eranthis cilicica, a Winter Aconite, one of our prettiest early spring gems, is much in evidence at present. Scattered individuals of a group of this species are appearing like miniature Toadstools. They stand erect, with golden-yellow, cup-shaped flowers surrounded by a whorl of pointed, green sepals.

Helleborus viridis and H. corsicus are endowed with constitutions to withstand severe weather. They bloom and flourish at this time like the Snowdrop and Leucojum. Shapely plants of Erica carnea var. Winter Beauty on a mound facing south, have lost none of their attractiveness. Their glorious hue has made them conspicuous and they have been admired for many weeks past.

The Crocus family seems to have shaken off any bad effects of frost. Species such as C. aureus, C. chrysanthus, C. biflorus and its variety Wildenii are wonderfully pretty.

During the hard spell of frost there was very little snow to give protection, and many plants would have been benefited by its presence. The gradual seven days thaw has now been followed by a fall of two inches of snow. This will give the necessary blanket to the many flowering subjects mentioned, should frost again assume its recent degree of keenness. *A. McCutcheon.*

FLORISTS' FLOWERS.

BORDER CARNATIONS.

In glancing through past lists and records, I was struck by a fact which cannot be denied, *i.e.*, the large number of varieties exhibited which were sent out years ago, and which keep their position in spite of novelties—stated, in many instances, to be improved forms of these varieties—which appear, and then often disappear very quickly, or at the best, subside into the background.

This cannot be because there are no novelties of a stirling individual character put into commerce, for although one does not expect every variety sent out to be of exhibition form, there are always some that are outstanding, and one might reasonably suppose amateurs would welcome an opportunity of trying newcomers which have, besides merit, variety in markings and shades. But at least two or three seasons elapse before a really good sort comes under general notice, the majority of amateurs preferring to wait and see how the novelties behave in the hands of the few who are always willing to pay for them. While certain of the older varieties are still unique in colouring, another great factor is the persistence with which seasoned amateurs stick to them, and the pardonable conceit some of them have in the manner they are able to show, year after year, blooms which the younger generation would not know how to grow to such perfection, for there is no doubt that many varieties do require understanding; of these, mention need only be made of Pasquin, Elizabeth Shiffner and Queen Eleanor.

The first-named is probably still the loveliest yellow-ground Fancy in commerce (the only one to bracket with it being Lieut. Shackleton) and appeared in 1908, the other two being introduced in 1910 and 1911, respectively. That Pasquin is difficult, even under glass, is admitted, and Elizabeth Shiffner will look entirely unlike itself if the unique colouring is not secured; while Queen Eleanor has such a weak neck that, although it was acclaimed when first sent out, it has almost entirely ceased to be grown, except by expert Carnationists, who know what a really beautiful show Carnation it can be; one good point in its favour is that it is an extraordinary grower in light loam in the open border, making a huge plant if left unchecked, and giving abundance of blooms. It is, however, liable to split its calyx.

One other old variety I should like to mention is Edenside. Appearing in 1913, no other Border Carnation is quite like it, and although still listed, it is now very seldom seen. That it is somewhat difficult is again, possibly the reason for its scarceness, while, some also assert the calyx is weak, but, like Linkman, it should not be discarded until a strong variety of the same colouring takes its place. Incidentally, there is a novelty named Linkboy now being sent out, which, it is confidently asserted, will sweep Linkman into the background. Linkman has a weak neck and stem as its chief drawback, but Linkboy will have to justify its reputation very completely as to stem, form and colouring, before the old favourite is ousted, one of its greatest assets being its excellence on the open border. A stronger grower of this type would be very welcome, however, as it is alone in its particular shade.

Three other novelties which I have not previously noted are Corinthian and Florence Welstead, white-ground Fancies, and Allan-a-Dale, yellow ground. The first-named is lightly marked and fringed with crimson-scarlet, the colour forming a solid edge around the petals, which are slightly cupped, although this does not always detract from the appearance of its blooms. Its companion, a large bloom with broad petals, is marked with light scarlet, and I was much taken with it when, exhibited last summer as a seedling, it secured first prize. Allan-a-Dale I have not seen, but the ground is stated to be deep yellow, with light markings of bright scarlet and maroon. It is stated to have the same massive proportions as Edenside, a strong and compact habit of growth, and is very floriferous; it appears to be an exceedingly attractive variety.

Although the severity of the weather will no doubt cause some losses, the Border Carnation, either in pots or the open border, if healthy and well-rooted, reacts very quickly, and frozen plants come out of the ordeal and start growing so soon as climatic conditions permit. Some very fine and reliable Fancies for general purposes have been sent out during recent years, but very few first-class Selfs appear, as is evidenced by the blooms exhibited, few being of very recent introduction, except, perhaps, Joan Wardale.

Snowflake is the almost universal white, and Bookham Scarlet, Mary Murray, Gordon Douglas, still one of the best; Joan Wardale, Roderic Dhu, Effie Deans, E. Shiffner, Mrs. P. Smith, Bookham Rose, Peach Blossom and Yvonne Thomas, appear with monotonous regularity. Cockatoo, a beautiful variety, is now becoming better known, and the new scarlet Regina is magnificent in the border, but apart from some other of the stirling older varieties, those mentioned are practically ubiquitous in the south. Shirley Surprise, Shirley Coral, John F. Woolman and Leslie White, are all good for both border and exhibition purposes, the last-named being a fine rose-coloured sort. Although there are so many claimants to the title of "finest" among white ground Fancies, it would be impossible to state which one should bear it, and it would take us back very far in the matter of introductions, for Mrs. Hanksbee and Fair Ellen are still in the running, and in spite of two or three improved varieties, many consider Mrs. G. D. Murray unsurpassed. When one considers that since Mrs. E. Charrington was introduced there have been Mrs. F. W. Seymour, Mrs. J. Fairlie, Yenton, Esme Murray, A. St. Clair Amos, Flora McIvor, Evelyn White and Bookham Beau, among other excellent varieties, it must be confessed that individual taste will always exercise the casting vote, the same form and colouring not appealing to all.

The autumn of 1922 gave us Highland Mary, which entirely replaced Loveliness and Viceroy, and no yellow ground Fancies have surpassed them up to date. The last was a good season, several standard varieties being sent out, among them Dr. Connor, with unique markings and a splendid seeder. I should select Clio, Endymion, King's Jester, Flamingo, Idwen, Ivan Lowe, Doreen Woolman, Mrs. H. Lakeman and William Preston, M.P., as new varieties which stand out and are good growers. I admire Chieftain very much, but its "grass" is somewhat difficult to handle. I have not included Florence Grisby, as I want to try it over this winter, but I hope it will maintain its reputation and become a standard variety.

There are certain older varieties in this class, which, while maintaining their position, might very profitably be grown to a greater extent. Kathie Moore, for instance, is a lovely flower, and good for the border, as also are J. J. Keen, J. Saville, Peace Treaty and Shirley Fancy, which has a very lasting bloom, prettily marked. I am giving Radio attention, as its habit of growth is good, and the colouring, somewhat after the style of Highland Mary, not overdone.

Fancies continue to make headway, and fresh classes are being inserted in schedules in order to bring them into further prominence. Breckenborough Hall, sent out last season, seems to have inspired more interest than most novelties, probably because of its colouring, allied to a strong Clove perfume, and robust constitution. It should tone well with its parent, Mrs. A. Brotherstone.

Ebor is a fine variety, worthy of all praise, and stated to be an improvement on The Cadi. As the colouring is different, and the latter is almost perfect in shape and constitution, this description of Ebor is rather misleading. Ebor is, perhaps, a larger flower, but there is room for both these lovely sorts, and no one having grown The Cadi will willingly discard it. To complete a trio of similar shading, I add Verdun, which will give perfect blooms.

F. W. Ransome is shapely, and seems as if it would be a reliable variety in regard to fixity, but Albert E. Amos, with its occasional red ticking, is very often a rose Self, the marking being entirely absent. This sporting cannot be eliminated altogether, particularly where the markings are of a very slight nature, but a variety should not be discarded on this account, as the layers from any plant may produce blooms perfectly true to type.

I have been receiving many enquiries as to the cause and prevention of stem-rot, a disease which is playing havoc with Carnations in certain districts, many midland growers suffering from it severely. The trouble is that there is no agreement as to its origin, but the soil must undoubtedly be the first consideration. A correspondent who deprecates the use of calcium oxide as being too caustic in its action, finds that calcium carbonate, finely distributed, has a most beneficial effect on the plants, enabling the soil to be quite reasonably enriched in humus and chemical foods without deleterious consequences, both necessary if the large flowers, which are called for at present, are to be produced successfully. As he points out, the Dianthus family originally came from rocky areas, where the drainage is good and the soil poor, and it is obvious that, while cultivation calls for the application of stimulants, fundamentally, the soil and conditions of growth must approximate, so nearly as possible, those of the original stock. This, of course, is feasible, but in my own opinion, it must further be seen that where varieties, however healthy originally, are grown on repeatedly, and layered in a too acid soil medium, arising from continued over stimulation, particularly chemical, weak stock must inevitably result, which cannot resist a disease arising, as it does, from the very food on which the plant depends. This, I believe to be the principal cause of stem-rot. In layering, too, sand which is overcharged with iron, or fine sand used to excess, which packs close and thus causes insufficient drainage and a sour soil, is often the primary cause of a hardening at the joint, especially if the layers are left in this medium too long after becoming well rooted. If the soil into which they are transplanted is not compounded carefully, or if peat or leaf-mould is included, which over-feeds and debilitates the plants, disaster is bound to occur if pests of any kind attack, as there is not sufficient resistance in the constitution of the layers to withstand disease, especially where the parent plant has been stimulated beyond its powers in order to obtain abnormal blooms, and has no superfluous energy with which to help its offspring.

Old mortar-rubble is, without doubt, one of the finest materials to incorporate in any soil for Carnations; it can do nothing but good, and with it very little sand is required. My own soil is light, and consequently I use very little lime (calcium oxide), but I do advocate a free use of freshly-ground oyster shells. It greatly adds to the beauty and sheen of the petals, and seems to supply a want that no other form of lime does. Every Carnationist has some different method of procedure, but the most successful in the long run are those who grow their plants in a clean, healthy compost, without undue coddling, or over stimulation, either chemical or organic. *J. B. Wells.*

THE GENUS PRIMULA.

(Continued from page 166.)

LEUCOPHYLLA (Pax). Milk-leaved P.
(Vernales.)

This perennial species somewhat resembles the Oxlip in flower. It produces a tuft of rugose, rather leathery leaves, with oblong or elliptic, blunt blades, tapering to a narrowly-winged stalk about equalling the blade in length, in all one-and-a-half inch to three-and-a-half inches long; margins nearly entire or bluntly toothed; underside covered with whitish wool. Flower stem nine to ten inches tall, downy when young, smooth when in fruit, bearing an umbel of numerous pale yellow blossoms. Corolla about three-quarters-of-an-inch across, divided into five broadly heart-shaped, cleft lobes; tube cylindrical, but little longer than the calyx. Introduced in 1896.

Grows in mountain limestone pastures, in the eastern Carpathians and the Caucasus, up to 10,000 feet above sea-level.

Var. longipes (Pax). In this form the margins of the leaves are crisped and crenulate. Eastern Carpathians.

Var. Ruprechtii (Pax). The margins of the leaves of this variety are minutely crenulate-dentate or nearly entire. Caucasus.

Culture: As for P. elatior, with the addition of limestone to the compost.

LEUCOPS (W. W. Sm.). White-eyed P.
(Nivales.)

A desirable, minute, deciduous perennial species, with a dense tuft of narrowly lance-shaped, pointed leaves, half- to one inch long gradually tapering to an indistinct, winged stalk; margins revolute, nearly entire or edged with obscure, rounded, regular teeth; upper surface more or less smooth, underside coated with yellow meal. Flower stem one inch to two-and-a-half inches long, slender, bearing an umbel of two to five fragrant, lilac, mauve, or purple blossoms, with a white eye. Corolla nearly flat, about half-an-inch across, with sub-rotund, entire lobes; tube cylindrical, dilated upwards, about half-an-inch long. Flowers from May to July.

Grows in open alpine pastures and on mountain slopes at Gujala, in the Muli district of south-western Szechuan, at 15,000 to 16,000 feet above sea-level.

Var. anopa (Hand.-Mazz.), has leaves hardly half-an-inch long, coated on the underside with white meal; north-western Yunnan, at about 14,000 feet above sea-level.

Culture: Plant both the species and variety in good rich loam in an open, damp spot, and afford protection from damp in winter.

LHASAENSIS (Balf. f.). Lhasa P.
(Obtusifolia.)

This plant is possibly but a microform or sub-species of P. Jaffreyana; it has a short, thick rootstock which produces a rosette of oblong-spathulate, pointed leaves about three inches long, with somewhat cartilaginous margins furnished with unequal, sharp teeth; upper surface gland dotted, underside more or less covered with yellow meal; the blade tapers into a short, winged stalk, dilated and sheathing at the base. Flower stem about six inches tall, erect, more or less mealy above, bearing an umbel of four to eight violet blossoms on erect, slender, sparsely mealy stalks, about one inch long. Corolla about five-eighths-of-an-inch across, divided into five broadly wedge-shaped, very deeply bifid lobes; tube narrowly cylindric, slightly dilated upwards, with a delicate ring in the mouth. Flowers in August.

Grows on hill-slopes near Lhasa, in Tibet.

Culture: Fibrous loam and limestone chips, in damp, but well-drained, open situations, is indicated.

LICENTII (W. W. Sm.). Abbé Licent's P.
(Malacoides.)

An extremely interesting species, the most northern member of the group to which it belongs; it has a slender rootstock which produces a tuft of numerous spathulate or broadly lance-shaped, membranous leaves, wedge-shaped at the base, not heart-shaped, gradually contracted into a narrowly winged stalk more or less equalling the blade in length, in all about three-quarters-of-an-inch long; margins edged with coarse, irregular teeth; both surfaces clothed with very minute, meal-producing hairs. Flower stem about six inches tall, bearing one or two superposed umbels of four to seven lilac blossoms on slender, sub-erect stalks, half- to three-quarters-of-an-inch long. Corolla about five-eighths-of-an-inch across, with heart-shaped, notched lobes; tube cylindrical, about five-eighths-of-an-inch long. Flowers in May. Not in cultivation.

Grows on the mountains in the Province of Shan-si, in northern China.

Culture: As for P. Forbesii should suit this species. It should prove perfectly hardy in cultivation.

LICHIANGENSIS (Forrest). Lichiang P.
(Cortusoides.)

A hairy, perennial sub-species of the variable P. polyneura (Fr.), with a tuft of oval leaves from two to five inches long, heart-shaped at the base, borne in hairy stalks two to six inches long; margins divided into numerous rounded lobes; both surfaces hairy and strongly veined. Flower stem six to fourteen inches tall, slender, hairy, flexuous, bearing loose umbels of fragrant blossoms varying from light rose to nearly crimson, on fairly long stalks. Corolla about five-eighths- to one inch across, flat, divided into five heart-shaped lobes; tube cylindrical, longer than the calyx. Flowers in June and July. Introduced in 1908. *Gard. Chron.*, Suppl. Illus., December 30, 1911.

Grows in somewhat shady places on limestone cliffs and boulders, on the eastern flanks of the Lichiang Range, in north-western Yunnan, at 10,000 to 13,000 feet above sea-level.

Culture: Good loam and leaf-soil, in a well-drained shady spot, suits it best.

LIMBATA (Balf. f.). Bordered P.
(Nivales.)

A handsome, deciduous, perennial species with short, scaly resting buds coated with white meal and tufts of somewhat leathery, narrowly egg-shaped, pointed or blunt leaves, tapering to a hardly distinct stalk, in all from two to four inches in length; margins furnished with sharp, uneven teeth as though gnawed by insects; both surfaces coated with grey or white meal, underside densely so. Flower stem stout, rather more than nine inches tall, slightly mealy upwards and bearing a many-flowered umbel of fragrant, violet-purple or purplish-blue, grey-eyed blossoms on slender, short stalks; the purple calyx is also sprinkled with white meal. Flowers in June and July.

Grows in open, moist, stony pastures, or on the damp ledges of cliffs, on the mountains of the Mekong-Salween Divide, at about 9,000 feet above sea-level.

Culture: Grow it in good fibrous loam, in a damp spot, and afford protection from severe frost.

LIMNOICA (Craib). Mud-loving P.
(Denticulata.)

A beautiful member of the P. denticulata group, with a rosette of somewhat membranous, sub-erect, lance-shaped or oblong-lance-shaped leaves, broadened and bluntly rounded at the tip, tapering at the base into rather narrow, winged stalks, in all about three inches long; upper surface more or less smooth, underside sparsely mealy, margins furnished with sinuous teeth which are minutely toothed. Flower stem six to twelve inches tall, stout, covered with yellow meal towards the top, bearing a head of lavender-blue blossoms. Corolla about five-eighths-of-an-inch across, divided into five rounded, bilobed segments; tube cylindrical, about three-eighths-of-an-inch long. Flowers in March and April. This plant, according to Professor W. Wright-Smith, is a sub-species of P. alta (Balf. f.). In cultivation in 1922.

Grows in wet soil on the banks of streams and also in drier situations on hillsides, in Upper Burma, at 7,000 to 9,000 feet above sea-level.

Culture: As for P. denticulata.

LIMPRICHTII (Pax et K. Hoffm.). Limpricht's P.
(Petiolaris-Davidii.)

A handsome, perennial species with a rosette of sub-orbicular or rounded-oblong, dark green, somewhat leathery leaves two to four inches long, heart-shaped at the base, borne on distinct stalks about half the length of the blade and densely covered with reddish down; margins furnished with shallow, obscure, rounded lobes; upper surface non-mealy, dark green, bullate, underside clothed with short, stiff hairs. Flower stem two to six inches tall, downy below, smooth upwards, bearing an umbel of two to six reddish-purple blossoms, on smooth stalks, half- to three-quarters-of-an-inch long. Corolla from one to over one-and-a-quarter-inch across, with broadly heart-shaped very deeply notched lobes; tube cylindrical, longer than the calyx. Flowers in April. Not in cultivation.

Grows in Bamboo thickets near Kwan-hsien, in southern Szechuan, at from 7,500 to 8,000 feet above sea-level.

Culture: Good rich loam and leaf-soil, in a cool shady spot, with protection from severe frost in winter, are the conditions indicated.

LISTERI (King). Lister's P.
(Obconica.)

This deciduous, perennial species has a somewhat stout, woody rootstock and a tuft of very thin, rounded leaves one inch to two-and-a-half inches across, heart-shaped at the base, borne on very slender stalks, one inch to three-and-a-half inches long, usually covered with short down; margins lobed, lobes toothed or entire, pointed; both surfaces more or less covered with very fine, short hairs. Flower stem one to eight inches tall, slender, downy, bearing a loose umbel of three to eight blossoms of a rose-pink, rose-lilac, or lavender colour, or, at times, pure white. Corolla five-eighths- to one inch across, nearly flat, divided into five egg-shaped, bilobed segments, entire or toothed at the tip; tube cylindrical, longer than the calyx. Flowers in March and April. Not in cultivation. *Gard. Chron.*, Suppl. Illus., November 20, 1909.

Grows in Bamboo jungles, in limestone pastures, and on cliffs in thick moss, mostly in moist places, in shade, ranging from the Sikkim Himalayas eastward to the Tali range of Yunnan, reaching an elevation of 10,000 feet above sea-level.

Culture: Grow it in good loam, leaf-soil and limestone chips, in a half-shady spot, with an abundance of water when in growth. *A. W. Darnell.*

(To be continued).

POTASH NOTES.

Old observations are often lost to sight, although sometimes not without interest; occasionally, if adequately inaccurate, they may become immortalised by being handed on from text-book to text-book. The article on manures (Wurtz, *Dict. de Chemie*, 1868) recounts trials of potash manuring, with cereals, etc., wherein there was a crop reduction; someone had stated that potash would increase sugar, so several lots of Beet were tried. There was, indeed, an increase of sugar per plant, but the reduction of crop about equalised matters to that of the control. Tobacco came out better; potash starvation gave a leaf which would not burn well and yielded a black ash, but with potash manuring, good burning and a white ash resulted. Someone thought that potash would help to stop Potato blight, but trials showed that as many or even more rotten tubers came from the potash-treated, clamped Potatos as from the controls.

Coming to modern times, a remarkable claim is made (*Pomologie Française*, May, 1928, p. 111) for potash as an agent against the cockchafer grub (the *ver blanc du hanneton* which causes so much damage in France). It is stated that the application of sylvinite (chloride of potash) in February has a great effect, and although all the larvae may not be destroyed, it causes survivors to bury themselves deeply beyond the young roots of the seedlings. A patch of Wheat treated at the rate of 300 k. per hectare (about 2½ cwts. per acre) was not attacked by the mole cricket, although neighbouring patches were decimated; another trial on Wheat where the *ver blanc* was concerned showed that doses of 600 to 800 k. (5 cwts. to 7 cwts. per acre) were efficacious, and the grubs were found mummified in numbers. In a commune in Switzerland, it was reckoned that if all the hay area were treated, another half-ton per acre of hay would be saved from the cockchafers, and give food for another eighty cows, which would produce 15,000 litres of milk (say 3,300 gallons).

Similar results are claimed for kainit, which is more commonly marketed here. Strong solutions applied to the bark of fruit trees in winter are said to destroy both animal and vegetable enemies; even a twelve per cent. application seems to have nearly eliminated woolly aphis; five per cent. was used on the Currant or Gooseberry (*Groseille*). So far a veritable apotheosis of potash! for the potassic element is claimed to be the active partner but, finally, attention is given to the good effects of common salt (sodium chloride) on various fruit trees (Apple, Pear, Fig, Pomegranate, etc.), especially in improving flavour; the trees may safely be watered with one to one-and-a-half per cent. solution. The question may arise as to whether we pay sufficient attention to chlorides in applying artificial manures. As regards sodium salts, a short abstract from the *C. R. de l'Acad. des Sciences*, by MM. G. Rivière and G. Pichard (*Pomologie Française*, January, 1929, p. 5), states that experiments with carbonates of soda, potash, lime and magnesia resulted in better cropping with the soda salt than with any of the others—presumably fruit trees were tried.

Reverting to potash, mention may be made of the East Malling trials in respect to leaf-scorch on the Apple; the tables given by Mr. Grubb (*Jour. Pomol. and Hort. Sci.*, Vol. VII, 1928) of estimated percentages of affected leaves with and without potash manuring, are of interest. The figures are variable and in no case show a diminution to zero even after four successive years' application of potash. When we see that even after this history, Lord Derby Apple showed sixty-five per cent. scorched leaves (Table III) or Allington Pippin fifty-four per cent., a direct connection between potash and leaf-scorch is scarcely to be maintained.

Countervailing ideas are acceptable on this and the other side of the Channel on the two conditions—leaf-scorch and silver-leaf. Here we consider silver-leaf is due to Stereum purpureum; in France they consider this a very common fungus, which is usually not to be seen on silver-leafed trees; there they consider leaf-scorch is due to Cladosporium herbarum, which we regard as a very common fungus, and consider that leaf-scorch is not due to the presence of parasites.

Noteworthy was a wide-spread attack or prevalence of leaf-scorch (*brunissure*) all over the north of France in 1888 (a year following the hot, dry year of 1887) which attained *proportions extraordinaires*, so that, especially on Apple trees, all leaves were completely dried up on the trees by the end of July. It was then concluded that Cladosporium can attack the leaves of a large number of plants, notably of the Apple; here, in England, it still only attains the elegance of a saprophyte. So far, the fashion of the times for "virus" diseases has not yet clothed leaf-scorch—perhaps it may—*Quien sabe? H. E. Durham.*

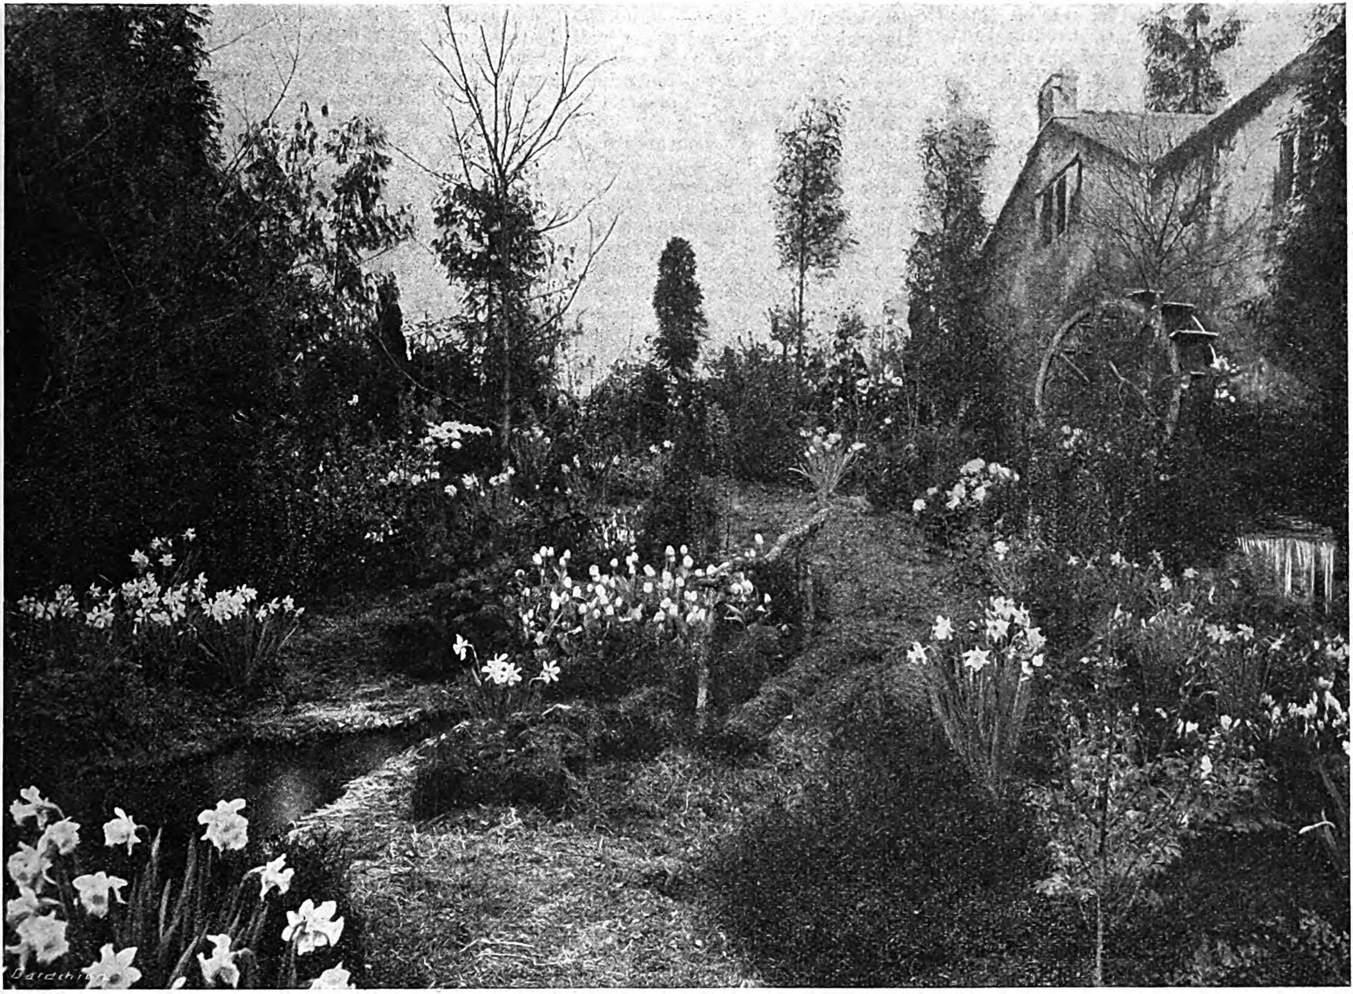

FIG. 93.—MESSRS. JAMES CARTER AND CO.'S OLD MILL GARDEN.

THE IDEAL HOME GARDENS.

THE gardens at Olympia, in connection with the Ideal Home Exhibition, have become an institution so popular that, although there is an extra charge for admission to the Annexe, there is often a greater proportionate number of visitors there than in the large hall. Although each year there are changes in the design and planting of the individual gardens, the general idea of treating the exhibits as indications of how garden areas of moderate dimensions may be laid out remains the same.

Probably few of the many visitors who derive so much pleasure from these gardens realise the almost heart-breaking difficulties under which they are often, and particularly this year, made. The disabilities of very limited time, and restricted space for working, and the transport of materials as well as plants of all kinds are as everyday matters to the nurseryman who exhibits a garden complete in every detail. That he has a rigidly defined, concrete-floored area for his exhibition garden, with very little extra space for the assembly of the materials and ten days only in which to carry out a more or less elaborate scheme, does not perturb him. Even, as this year, when to these difficulties are added the trials and tribulations of such severe weather as rarely occurs more than twice in a long life-time, the nurseryman-exhibitor rises superior to all hindrances and, at the appointed hour, presents a garden so complete and well-furnished in every detail that it might well have existed for several decades. Truly, the great flower show attending public owes him much more than it can imagine.

Comparisons are notoriously odious, and if the most critical were inclined to recall that on some former occasions the gardens were, perhaps, a thought brighter generally, and the turf more lush and trim, a comparison between the Olympia Gardens and those at home must engender feelings of pride in the great success accomplished by the exhibitors.

This year the general idea has been the country garden, and the scenic effects provided by the canvas draperies around the walls are especially successful. Where possible, most of the exhibitors have taken full advantage of this admirable scenery, and made most fascinating peeps and vistas. This is especially noticeable in the Old Mill Garden of Messrs. James Carter and Co. (Fig. 93). By the art and skill of their planting and their lighting effects they have obtained the delightful impression of a garden overlooking a placid countryside bathed in warm sunshine. The suggestion of the old mill is very clever, and many visitors found a thrill in gazing at the mill, whose attendant water-wheel turned slowly and rythmically, passing the water along a lazy little stream to the pools below. Rustic bridges span the stream, and grassy paths wind about the slopes where are flowers galore. The garden making and planting are of that studied disorder which betokens the highest art. The naked Birches rising above masses of early Pyruses and Prunuses, bordered with dwarf Rhododendrons and Azaleas, and a galaxy of Daffodils, Tulips and Dielytras, make a garden of great fascination and contentment.

The brightest colour in the gardens is provided by the delightful bushes of Rhododendron Warrior, by the terraces of the garden of Messrs. R. W. Wallace and Co., where the large, rounded trusses of glowing reddish-pink blooms light up the greensward. A pleasantly-winding paved path leads up to a comfortable garden house which is flanked by shrubberies of Prunuses, Viburnum Carlesii, flowering Cherries, Lilacs and other spring shrubs, and gives place to a rock garden, and on to plantings of Daffodils, Tulips and Iris reticulata. In their allotted space, Messrs. Allwood Bros. show that a satisfying garden may be made of Carnations and the allied Dianthus Allwoodii without the aid of other plants. It is chiefly a formal garden, with a small rock garden for the Dianthus Allwoodii and, as may be expected, the Carnations are of the greenhouse, perpetual-flowering varieties.

A paved garden of homely character and of considerable brightness is provided by Messrs. J. Cheal and Sons. This is essentially a spring garden, and in it are many floriferous bushes of Diervilleas, shrubby Spiraeas, Pyruses, Prunuses, Lilacs and Brooms, with heavily-flowered Rhododendrons and deciduous Azaleas. Daffodils are freely used, and in the small, formal portion there are beds of Primulas.

The Central Gardens Supply Co. have made a series of gardens of different types all coordinated into a harmonious whole. Their garden house, treatment of the slopes, and rock garden are especially successful and within their area would be found something of interest throughout the year. The garden of Mr. Herbert Brooks is more of the open spaces, and he has relied on the natural treatment of a moderately large slope, where he has an informal rock garden with stream and pool. The Peter Pan garden of Mr. Burton Holt, which, by the way, has grown up higher than any other in the Annexe, attracts many in search of novelty. The Orpington Nurseries' exhibit is of moorland character, with informal boulders and water, lightly planted with Heaths and various alpines.

A very uncommon Japanese garden has been made by Mr. George G. Whitelegg. Placid, little canals, crossed by flat stones on piles of a Conifer, presumably Cryptomeria japonica, enclose an island wherein is an attractive temple with attendant stone lanterns of conventional eastern design. Outside the canals the ground has been generously planted with exceptionally good specimens of double Cherries, Wistarias, Pyruses and Peaches. A breadth of heavily-berried bushes of Skimmia japonica is also very effective. The hammered gate which opens to the paved path leading to a sundial in the garden of Mr. Ronald S. Skelton, is a particularly happy thought. Within the garden there are plenty of Forsythias, Magnolias, Berberises, Spiraeas, Pyruses and Azaleas. Messrs. Bakers have an attractive Heath-clad slope, with an appropriate garden house in the higher corner, while on lower ground there is a walled portion, and a good shrubbery border.

Considerable space has been allotted to the Country Service Association, whose hillside planting, with informal rock garden and gentle stream with pool, is especially effective. Elsewhere they have a semi-wild garden with stone dove-cote and, on the opposite side of the pathway, a formal garden thickly planted with Anemones. Nearby, Mr. Whitelegg has a second garden ; this is of more formal character, with terraces and pool, suitably planted. Mr. Baldwin Pinney has made a formal garden, and in it he shows well-flowered Violets, Primula Wanda, P. kewensis, P. malacoides and others. Mr. John Klinkert has his customary topiary garden, where he displays a great variety of perfectly pruned examples, mostly in evergreen Box.

The Sunny Hour Villa Garden is presented by Messrs. L. R. Russell, Ltd. Here they have, in a very effective centre, the best turf in the building, and the rustic, Heather-thatched summer-house is very inviting. The beds of dwarf Japanese Azaleas, and the neat rock garden find many admirers. A good shrubbery border which encloses the garden provides fitting places for Magnolias, Forsythias, Camellias, Lilacs, Azaleas and many more shrubs. Mr. R. Crewdson Day has a formal garden, and Messrs. Windward are showing good Violets from the west of England.

In addition to their Old Mill Garden, Messrs. James Carter and Co. are responsible for the bright and attractive beds in the Spring Garden of the Tea Enclosure, where they have excellent Hyacinths, Daffodils and Tulips ; and also for the Sunshine Garden in another part of Olympia, where many Azaleas and Daffodils add greatly to the attractions of the corner.

ON STOKING.

The recent spell of Arctic weather all over the country has given journeyman gardeners engaged in stoking duty the opportunity of proving their worth, and at the same time earning in no small degree the appreciation of their employers and the gardeners over them.

Stoking, at all seasons of the year, plays an important part in the success of a garden establishment, and it seems strange that a young gardener's abilities in this direction seldom figure in present-day references. In these days when all head gardeners have to study fuel economy, the young men who tend the heating apparatus and maintain the required maximum heat on a minimum supply of fuel can save their employers a considerable amount of money if they only exercise care and judgment, and carry out their duties conscientiously.

The chief fault with the majority of young men on duty is their over-eagerness to get the heat up, and consequently, should they be "called over the coals" when the temperatures are down on a certain morning, they go to the other extreme and have the temperatures too high the following morning, little realising that a very high temperature is as injurious to plant life as a very low one.

The practice of governing the heating of a range of houses heated by one boiler, by the thermometer in the hottest house, has its advantages, for the man on duty knows that if the temperature in that particular house is correct, the others will be correct if the respective valves are opened sufficiently. The opening and shutting of valves according to weather conditions should at all times be left to the supervision of one man—for preference, the inside foreman—for it not infrequently happens that, unless one person alone is made responsible, when the temperature drops quickly the man on duty turns a little extra heat on, the foreman goes round soon after—before the temperature has time to rise,—and turns a little more on, and later, the head gardener does the same, with the result that too much heat is turned on, to the detriment of the plants.

Another important point which young men should pay more attention to is to keep the fires well back during the day time, when the sun causes the temperatures to rise, for unnecessary heat in the pipes on bright days tends to bring about attacks of red spider. During the lengthening days, when a few hours of bright sunshine are followed by a sharp frost at night, the fires should be started early in the afternoon and the houses shut before the sun sets, thereby keeping the temperature up with the sun-heat—this applies especially to fruit houses —for if a steady circulation of heat is maintained through the pipes before the sun sets, it is easier to keep the houses at the required temperatures, rather than to let the temperatures fall and then have to force the fires to get them up again.

The ash-pit under the boilers should be cleaned out at least once a day and the flues once a week—for preference, on the day the man on duty gives place to his successor, and all air taps should be examined periodically to release any air that may be in the pipes, and preventing the circulation of the hot water. During severe weather the pipes in cold fruit houses should be kept warm to prevent them freezing ; should the water in them get frozen, the air taps should be opened prior to turning on gentle heat, to prevent the pipes bursting. The essentials which make a good stoker are consistency, the careful usage of fuel, and the ability to keep the temperature at a happy medium—not too hot or too cold. *A. J. Turner, Newton Park Gardens, Burton-on-Trent, Staffs.*

HOME CORRESPONDENCE.

Professional Gardeners.—Between three and four years ago, a gentleman in the north of England applied to the Secretary of the Professional Gardeners' Association for a gardener. He required a really good man. The Society found him one who satisfied all his requirements. Unfortunately, from the employer's point of view, his gardener has suddenly decided to go to one of our dominions, and his employer would like the P.G.A. to fill the vacancy. This the Society has great difficulty in doing, as, at present, there is not a member on the books who is wanting work. Consequently, the situation was advertised in *The Gardeners' Chronicle* under a box number. Applicants were asked to state wages required, with house, etc. The wages asked ranged from 45s. to 60s. The previous gardener's wage greatly exceeded the highest amount mentioned and, in spite of the numerous applications, the situation, at the time of writing, is still open. Had some of the applicants for the situation belonged to the P.G.A. no doubt one of them would soon have been filling the vacancy. Now, my fellow gardeners, it is time that all gardeners should join hands and increase the ranks of the P.G.A. Let us have a branch in every large centre of the United Kingdom. There is not the slightest doubt that it would be to the advantage of both the employer and employee. The employer, through the agency of the Association, obtains a man trained in the gardening profession, who knows his work and who is not afraid of the hard work and long hours entailed in order to make his garden both a pleasure and a profit. There is a feeling prevalent in sections of both employers and employed that a garden is only a luxury. Now this is a fallacy, for most gardens are, from two points of view, exceedingly profitable. The vegetables and fruits provide a large percentage of our national food, while flowers admittedly give great pleasure. I well remember Mr. Greenfield telling me that, when he was engaged on food production work for the Government during the war, the flowers he grew did more for the wounded, and for the overworked people at home, than all the food he produced. We know, too, that during the war it was the shortage of vegetables (especially greens) which was the cause of so much skin trouble and internal complaints generally. I think all will therefore agree with me that gardens are vitally necessary for the welfare of the community, so that we want the right men for the gardens, gardeners who have been trained from their youth. A good gardener has a true knowledge of his worth. A £2 per week man is generally only worth £2, but a man who can justly ask £4 per week can, and will, get it to-day in a great many cases. The Professional Gardeners' Association is a growing body and any gardeners desirous of information about it should apply to the General Secretary, Mr. G. Reid, Polland Hall Gardens, Gomersal, Yorks. Mr. Reid is a man of large stature, and with a large heart, whose ambition it is to see the gardener's wages and status improved. I see in *The Gardeners' Chronicle* for February 2, that Mr. Batty would like to see an association for gardeners ; the P.G.A. is what he is looking for, as it is run on non-political and non-compulsory lines, for the uplifting of horticulture and to create a more amicable feeling between employer and employee. *H. B.*

Ivy.—There is one garden use of Ivy to which our learned friend, the Rev. Hilderic Friend (p. 100), made no allusion. I refer to the old-fashioned baskets, perhaps these were Victorian and so, of course, quite discreditable in these days, which in a formal garden possibly yet deserve some merit. A deep, circular hedge of Ivy was formed around a flower bed, and an arch clothed with it was trained to form the handle. If memory serves me, some such were a feature in the garden of the late Sir Sydney Waterlow, now Waterlow Park—perhaps they still survive there. *H. E. D.*

Early-flowering Chrysanthemums.—The account of trials carried out by Mr. Sherwell-Cooper (p. 102, February 9), is of great value, and comes at a time when lists are being prepared for this season. Having possibly had less rain—25·75 inches during 1928—than Cheshire, several of the varieties mentioned did admirably, notably Periscope and Peerless ; these we are growing more of this year as they were extra good in colour and size of flower. *G. H. Emmett, Taplow.*

Partial Sterilisation of Soil.—I have been greatly interested in the many letters published recently in *The Gardeners' Chronicle* on this important subject, and would like to state my opinion. Mr. Falconer (December 22, 1928, p. 494) stated he has tried both the baking and the steaming methods, and has come to the conclusion that the latter gives the better results every time. My experience has been similar to Mr. Falconer's, and, although at one time I strongly favoured the baking process, the numerous experiments I carried out proved beyond doubt that steam sterilisation is by far the best for the average grower. The plant I use at the present time is the Sterilatum, made by Messrs. Jones and Attwood, of Stourbridge, and one which was recently mentioned by Mr. Falconer in his remarks on the different plants available. Although not large enough for the commercial grower, it is undoubtedly a first-class machine for the private grower, and a few remarks as to its construction and method of use may be helpful to those who may be on the look-out for an efficient plant at an economic price. The water container beneath the soil compartment has a capacity of fifteen gallons, and when this has been filled, the fire is started in the fire-box beneath. The compost is then placed in its container and covered with the lid. The fire is lit at 9 a.m. and, except for being stoked up an hour later, requires no more attention until the soil is ready for removal to a clean potting bench at noon, another quantity of soil being treated during the afternoon. The plant will sterilise from eight to ten good barrowloads of soil a day if filled twice, at the very low consumption of three bucketsful of coal. The advantages gained by the steaming method are: The soil is cleared of harmful agencies, so that the ammonia-producing bacteria may increase rapidly; the plant food in the soil is retained and often increased; and the soil is in perfect condition for use almost immediately after being taken from the container. On the other hand, baking the soil to a state of absolute dryness creates an excess of potash, which naturally renders the soil unfit for plant life; the humus in the soil is reduced to a fraction of its value, and at least a month must elapse before the soil may be used with any degree of safety. As an experiment, I would strongly urge any grower who is undecided as to the best method, to pot up half his batch of Cyclamen seedlings in soil which has been sterilised by the baking process, and the other half in steam-sterilised soil, and to note the difference in their appearance three months hence. *Henry G. Gibson, Surbiton.*

Cyclamens.— I enclose a photograph (Fig. 94) of Cyclamens which were greatly admired in Dublin last year. The seeds were sown in the previous August, in pans containing a compost of two parts loam, one part leaf-soil and sufficient sand to ensure drainage; the pans were then placed in a warm propagating house and when germination took place they were placed near the roof-glass and kept shaded only from strong sunlight. When fit to handle, the seedlings were pricked out two inches apart, in large pans, in a similar compost to that described, but with dried cow manure added. In these pans they were grown on until February, when they were potted into four-inch pots, in a similar compost; as these pots became full of roots, six-inch pots were provided and less sand was used in the compost. During July, August and September, the Cyclamens were kept in a cool house where plenty of air was admitted day and night, and shading afforded during strong sunlight. In October, the plants were moved to a house where the temperature was never allowed to fall below 50° or rise above 65° during the winter, and the result was a bountiful supply of blooms over a long period. The whole secret of success may be summed up in a few words—unvarying temperature, the proper use of the watering-can, plenty of air, avoidance of cold draughts, shade in summer (from strong sunshine only), and freedom from insect pests. *C. J. Leonard, The Gardens, Howth Castle, Co. Dublin.*

Number of Florets in an Exhibition Chrysanthemum.—The publication of the various counts of florets in exhibition Chrysanthemums has proved most interesting thanks to *A. C. B.*, for counts of older varieties, and also Mr. Street (p. 145) for a more recent introduction. Owing to the great disparity between the number of florets contained in the different varieties mentioned, I should like to suggest an analysis of the specimens dissected. *A. C. B.'s* Japanese bloom, *e.g.*, Madame Carnot (a variety I can just remember) had rather narrow florets, although it built up a huge flower; the variety Wm. Turner, of the Japanese Incurved type, has somewhat narrow florets very closely packed together, whereas the variety Louisa Pockett is a much coarser flower, having thick, leathery florets, many of the first to open being tubular, while the later ones are often fully half- to three-quarters-of-an-inch wide, thus requiring much sustenance from the plant to carry them through to perfection; this undoubtedly accounts for the smaller number of florets it contained. *A. W. Warner, Hamble Cliff.*

Root-stock Problem in Apple-growing.—My attention has been called to an article in your issue of February 23, on the above subject. The writer, Mr. H. Howard Grace, finishes his letter by stating that "Apple trees overseas are mostly standards, and that eventually they will be the same here." This is quite contrary to fact as regards our chief competitors, such as those in British Columbia and the western States of Washington, and Oregon. The former of these is now the leading Apple-growing State of the Union. As a few years ago I had the pleasure of visiting many of the Apple-producing districts of these north-west States, I can state that all the newly-planted orchards are of what we call bush trees, that is, they have no tall, bare bole. As they get older, some of the bottom branches may be cut off, if very low. In a country where it is necessary to spray from four to six times per annum, it is absolutely necessary that the trees should be kept fairly low. In the States that have severe winters the stocks are brought inside, grafted a few inches above the ground level, covered with sand until the frost breaks, and then planted in the nursery rows. In Australia, where I spent the best part of my life, the Northern Spy stock has been generally used for more than forty years, as this is immune to woolly aphis. This stock is also worked chiefly by budding a few inches above the ground level. These stocks are generally produced from stools, thus ensuring their being true to type. In these days, when quality counts, and this can only be obtained by spraying and thinning, low trees are more than ever desirable, and do not require a forty-runged ladder to enable workers to deal with them. *J. C. Alpars, Te Hongi, Longford, Gloucester.*

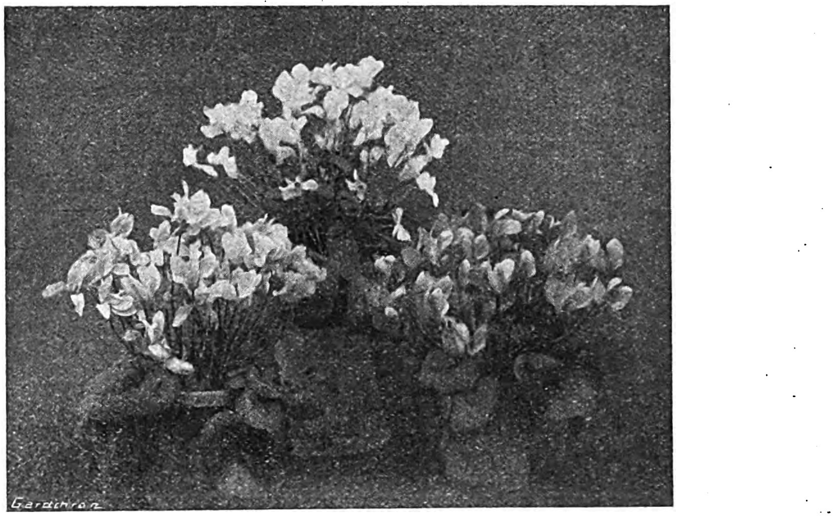

FIG. 94.—CYCLAMENS EXHIBITED AT DUBLIN.

Lapagerias.—*W. P. W.* (p. 145) writes of his experience in the grand old establishment of Messrs. James Veitch and Sons fifty-two years ago. It is quite refreshing to meet (even in print) one of the veterans of those good old days, and does one good to think of the fine men who were the departmental "chiefs" of those times. Your correspondent will, no doubt, remember Mr. Dominy, Mr. Manning, Mr. (as he then was) Harry and Mr. Arthur Veitch, among many others, most of whom will have joined the great majority. Many useful lessons did young men learn in that splendid establishment, which have stood them in good stead in the years that have followed. The fine display of the Lapagerias as well as Orchids, Azaleas, etc., will, as your correspondent observes, never be effaced from the memory. *W. A. Jenkins, Ropner Park, Stockton-on-Tees.*

What Shall we do with our Greenhouses ?—This is a problem that those with glasshouses have to face. Large areas of glass are not wanted; general expenses are high; taxation makes the upkeep difficult, and the garden consequently suffers. Here, a large area of glass has been nearly obsolete since 1916. Last year we were asked to take it in hand and see what could be done with cold houses. Backed up by an interested employer, the first step was to get them in working order—with repairs and paint. Four of them have been growing Peaches and Nectarines for some time and has been generally profitable, finely-flavoured fruits, with good colour, of Duke of York, Condor, and Peregrine Peaches, and Elruge, Pine Apple and Lord Napier Nectarines, being produced. One vinery only was retained, planted with vines of Black Hamburgh, Alicante and Appley Towers, all successful sorts. Two large vineries were cleared and the borders planted with fan-trained Apricots, the varieties being New Large Early, Early Moorpark and St. Ambroise, while single cordons of Plums, choice dessert sorts such as Jefferson, Oullin's Gage, Coe's Golden Drop, Transparent Gage and Denniston's Superb, were planted against the pillars. Apples, such as Cox's Orange Pippin, Ribston Pippin and Madresfield Court are grown against one of the back walls, and Pears, that love a warm, sunny wall, are grown against the other, the varieties planted being Doyenné du Comice, Louise Bonne of Jersey, Fondante d'Automne and Clapp's Favourite—all cordons. Choice dessert Gooseberries, as single cordons, to act as fill-ups, and to be removed when the permanent trees required the room, were also planted. Market growers have for many years filled their houses with annual flowers, Tomatos, Cucumbers and vegetables that were in general demand. Why should not private gardeners do the same ? Having memories of the old orchard house cultivation, as gleaned under such grand old growers as James MacGregor, George Woodgate and Thomas Coomber, V.M.H., surely they can readily adapt themselves to present day conditions when heat is so difficult to secure. Bed cultivation generally suggests itself in preference to pot work, as being more economical and profitable, especially having regard to the labour problem. Gardeners, as a class, must be broad-minded, hard as it is to keep abreast with changing conditions. It would be extremely interesting to hear the experiences and views of others, through the medium of *The Gardeners' Chronicle*, on this problem with which modern gardeners are faced. *G. H. Everett, Taplow Court Gardens, Bucks.*

Japanese Gardens.—Japanese gardens have been planned and planted in many English grounds, yet they must necessarily miss much of the true spirit of a garden of Japan. A Japanese gardener works much as an artist does, seizing what is unchanging and fixing it into a little imaginary world of diminutive trees, rocks, bridges and water. Colour comes with the Azaleas, Maples and Cherries. All seem to have lived just so from time immemorial. In his garden beautiful there must be nothing to suggest the transitoriness or mutability of life. Flowers which attain their loveliness and then linger on through slow stages of decay violate his sense of beauty, they are kept out. Hence the love for Cherry-blossom—yesterday but pinky buds, to-day a mass of snowy-pink loveliness, and to-morrow, touched by the breeze, off it goes a shower of pinky snow, casting as it vanishes the most delicate and refined of odours. There is no decay, nothing to allow one's mind to dwell sadly on what once was loveliness. *A. Telfer, Coxland, Ewhurst, Surrey.*

Effects of the Severe Frost.—"Yesterday Ross-on-Wye, Herefordshire, was again the coldest place in the British Isles." Thus the meteorological report has expressed it several times during February. Here we are seventeen miles from Ross-on-Wye, as the crow flies, and our lowest temperature was 36° of frost, 4° below zero. The damage to shrubs etc., cannot yet be definitely stated. Ribes speciosum, Senecio Greyii, Veronica Traversii and some others seem past hoping for, and such things as Pyrus japonica and Prunus (Amygdalus) Davidiana var. alba have their round, plump buds reduced to a soft, dry, spongy consistency. In ordinary years they are making a gay show by the end of February. This year we wonder whether the wood buds will have been also badly damaged. But the damage which strikes the eye in every direction is that sustained by Laurel, Portugal Laurel, Laurestinus, and even Holly. On the Laurels particularly, the leaves have been turned very brown; in some cases the green has entirely disappeared and we wonder what will be the ultimate result. I have never before seen such damage to these shrubs, and if any of your readers can state from experience whether it would be best to leave them alone to recover, or to cut them back, and, if so, when, I shall be very glad to have their advice. Enclosed are a few Laurel sprays which will give you a very fair idea of what these shrubs are like at present. *P. Murray Thomson, Bridge Sollers, Hereford.*

[The foliage was brown and withered.—Eds.]

Gardeners' Pay and Status.—As a young professional gardener, I would like to give my version on the subject of "Gardeners' Pay and Status." To begin with, gardeners are generally treated and classed as domestic servants, while some people put us on a par with agricultural labourers, and name us as "yokels." This alone is sufficient to cause our low status, and therefore low wages. Of course, we should be classified, treated and paid as skilled tradesmen or professional men. Secondly, there seems to be a tendency among employers to adopt a certain standard or accepted rate of pay (unfortunately low) which they offer in a "take it or leave it" style, knowing full well that they can easily obtain a man at their price sooner or later. This is where so-called gardeners, such as your correspondents have previously mentioned, can jump in, to the detriment of professional gardeners. My belief is that employers know that we are worth more money than we get, and they can afford to pay more, but will not do so because they fear we might develop a little spirit of independence; this they will not tolerate. Another point is that gardening is generally looked upon as unimportant and of no consequence. The majority of people think mistakenly that anybody can "mess about" in a garden; supply a man with a besom, spade, and a pair of shears, and he automatically becomes a gardener! I certainly agree with your correspondent, R. J. Pearson, that the big horticultural centres could, and should, do something to dispel the bogey of low pay and status, which seems to have existed in the gardening profession for years. Apparently the Professional Gardeners' Association, whose activities are reported in *The Gardeners' Chronicle*, is a step in the right direction, and these reports make very welcome reading. To do any good it must have men at the head who are alive to the needs of the gardening profession, men who have progressive ideas, and a go-ahead programme, with the necessary power to carry it through. A point of importance is that professional gardeners must shake off their apathy and enter into the spirit of the thing, and then join up in their thousands. Anyhow, anything worth having is worth working for! *B. C.*

——Your correspondents, *J. Batty* and *H. E. D.* (page 166) both bear out my experience, which might be worth mentioning. After about twenty years of sound, all-round training, I felt myself quite capable of taking a head place. I accepted what appeared to be a good start. The place was infested with Gout-weed, in clay, notably in about nine hundred square yards of herbaceous border. There was nothing for it but to make a clean sweep, so I raised hundreds of plants, wheeled the old stuff away, and replanted. I was rewarded by my employer saying she preferred the border in its former condition, and would I take away all the labels; inside a week, I was asked to label the plants in the herbaceous borders! I struggled on, somewhat crestfallen, replacing Sphagnum-moss pulled out of the Orchid pots, and being insulted by instructions on how to water plants. After two years of this I respectfully suggested that I might be credited with some knowledge of garden work, and for this crime I was relegated to the horticultural scrap heap, my nerves and confidence shaken. This was about eighteen months ago, and I find no fewer than four men have been thus treated. It seems scarcely credible that a person who "prefers" Gout-weed to a well-planned herbaceous border should be able to ruin capable, conscientious men, but such is too obviously the case. *G. D.*

THE NATIONAL IMPORTANCE OF FRUIT-GROWING.—II.

(Continued from p. 165).

In the previous article I dealt with the amount of fruit that is consumed in the country; in this one, I propose to deal with the amount that can be economically produced.

Mr. Seabrook, in his paper, when comparing conditions in British Columbia with those in England, states "land fit for fruit can be bought in England at from £15 per acre." This statement, as it stands, is rather misleading, as much cheap land is limited in the fruits that it will grow. While it is impossible to generalise about such a varying thing as land, farms which are bought at £15 an acre will generally need a considerable outlay before they are in a condition for planting fruits. On the other hand, there is good fruit land in British Columbia for which no buyer will make an offer, even at the price of ordinary land in this country.

It is almost as difficult to generalise on the subject of yields as on that of land; but certain definite averages are available which have been used authoritatively by the countries concerned.

American and Nova Scotian cost records, as given in the Report of the Imperial Economic Committee, 1926, are based on an average yield of four to five tons, while the Ministry of Agriculture gives the annual yield for Great Britain and Ireland for 1908 as 41 cwt. per acre, and for 1913 as 35 cwt. per acre. (These are the only British figures available and refer only to productive acreage).

This average yield of about two tons per acre must be compared with the arable farmer's average of thirty-two bushels of Wheat per acre, and taken as a standard. Although the farmer is not content with thirty-two bushels, and hopes to grow more, he would be pleased indeed if he were to double this figure, let alone treble it.

In Mr. Seabrook's paper, he gives the average yields of his two best varieties of Apple, namely, Bismarck and Worcester Pearmain, over seven consecutive years, as more than seven tons per acre. He refers to the comparative irregularity of the British crop with reference to other countries, but is fortunate himself in obtaining an average yield well above theirs.

It is only on a basis of average yields that any calculations can be made about the amount of fruit available for replacing that which is imported. But the facts given in the former article indicate that it would be no easy matter to capture the balance of the market for hardy fruits in this country. This indication is confirmed by the Report of Fruit Marketing in the Ministry of Agriculture's Economic Series, No. 15, where it is stated that the percentage of Black Currants produced in this country was 72·1 in 1924, and 72·9 in 1925. This indicates clearly that the fruit-grower in this country has a monopoly of seventy per cent. of the Black Currants consumed in England. Similar figures for Apples in the same years are 26·2 per cent. and 53·7 per cent., and for Pears in 1923 and 1924, 2·7 per cent. and 28·1 per cent. These figures, taken together, show very clearly what Mr. Seabrook refers to in his paper, that our home-grown supply must be regular to ensure a successful sale, and that continuity of supply is essential.

As is seen from the figures quoted above, where a regular supply is assured, as with soft fruits, then the home market is held. But where the supply is erratic, as with Apples and Pears, the percentage of the home market filled must vary from year to year.

These facts are demonstrated by the crop figures for Black Currants, Apples and Pears, in 1924 and 1925 and are, for Black Currants, 1924, 360,000 cwts.; 1925, 258,000 cwts.; Apples, 1924, 2,382,500 cwts.; 1925, 6,526,500 cwts.; and Pears, 1923, 23,000 cwts.; 1924, 495,000 cwts. These figures indicate a very clear measure of the risk attached to the growing of each crop. *A Norfolk Grower.*

(To be continued).

FRUIT GARDEN.

THE MANURING OF FRUIT TREES.

The results of the investigations carried out at Long Ashton, by Mr. T. Wallace, on the manuring of fruit trees in relation to quality, and which he has disseminated widely, has supplied a long felt want to gardeners, and particularly to commercial fruit-growers. A brief summary of these investigations will, I am sure, be of much interest.

Mr. Wallace, at the outset, states "there is no one best method of manuring to produce 'quality.' Each case is a particular one, and the specific objectives can be gained only by a thorough knowledge of the effects of the particular factors contributing to the final result and by modifying or utilising these in an appropriate manner."

High yield must be sacrificed for quality. In general, with mature trees, the highest yields will be obtained under a system of high cultivation, plus high manuring, either with dung or artificial manures; but the fruits produced under such a system, while excellent and profitable in early sorts—and especially in culinary varieties—are poor keepers, travel badly, and lack colour. The use of dung in considerable quantities will not generally result in the production of fruits of high market value. The fruits produced under such a system are generally of the large, poor-keeping, poor colour and easily bruised type.

The production of fruits of high quality may be most readily obtained by manurial means on trees such as the Apple, by the intelligent use of artificial manures and, in particular, by the use of quick-acting, nitrogenous and potash manures. Phosphatic manures, he states, have given no important "quality" results.

Mr. Wallace gives some very important "deficiency" results. Deficiency of nitrogen decreases yield, size and high flavour. The fruits possess less juice and are slightly sub-acid. However, it increases firmness of flesh, and promotes a red colour or a deep yellow ground colour, which no rich manurial ingredient gives to any notable extent. Deficiency of phosphorous decreases yield and size. The colour is only slightly affected, but the flesh is soft, while the fruits do not keep well and the flavour is very sour and unpleasant. Deficiency of potassium decreases yield and size. The fruits retain an immature appearance. The red colour is generally poorer than in ordinary fruits and the ground colour tends to remain green. The fruits are sub-acid, sweet to taste, lack juice, but store fairly normally.

Little is known, as yet, of the effects of excesses of the three above manurial ingredients on quality, with the exception of nitrogen. The most usual effects of high nitrogen are increased size of fruits, loss of colour, soft, juicy flesh, poor keeping and travelling qualities, but a high flavour.

The proportions of the three main nutrient elements to use in order to obtain high quality, vary with the condition of the tree. The balance of the nitrogen over potassium should not be too great, and it is unnecessary to apply large dressings of phosphatic manures.

Mr. Wallace is of the opinion that practically all the desired effects may be obtained by the use of inorganic materials. There are, however, certain types of soil on which he would undoubtedly supplement his "inorganics" with organic matter in some form or other. Soils containing high proportions of lime often yield highly-coloured fruits, but excellent quality fruits are frequently grown on slightly acid soils.

Late summer is regarded as the best time to apply these manures to young trees, and many prominent growers hold that late summer is also the best time for those of mature age. *H. H. C.*

BLACK CURRANT DANIELS' SEPTEMBER.

UNTIL the advent of this new variety, the season of the Black Currant was all too short. Fruits of the Red and White sorts will, if duly protected, hang until late October or November, but the ordinary Black Currant is past its best at the end of July. The demand for this fruit in the kitchen has led me for many years past to extend the season so much as possible, but, unfortunately, the larger and better-grown the berries, the more readily do they drop off.

Daniels' September does not even commence to ripen its fruits until the other varieties are over, and there is not the slightest difficulty in keeping sound fruits until the middle of September. This variety is of robust constitution, carrying good foliage; the fruit bunch is long, sometimes bearing so many as twelve berries of average size, and of exceptionally good flavour.

Its origin is similar to that of many other good fruits. A single bush was observed growing in a local garden. Its value was recognised and cuttings secured, but for several years the new variety was planted experimentally, both in field and garden. Not until its superiority was decidedly proved was it exhibited and offered for sale. In 1916, it gained the Award of Merit, followed by a First Class Certificate in 1921, from the Royal Horticultural Society. The exhibit was of sprays cut from bushes grown in the open field, and the berries in August were so firm and fresh as to attract much attention.

My own experience on our rather light soil is very favourable, and I understand that Messrs. Daniels Bros. are backing it heavily, having already forty acres of this variety planted out for fruit-bearing alone. *J. Comber, Nymans Gardens, Handcross, Sussex.*

VEGETABLE GARDEN.

CUCUMBERS IN FRAMES.
